His son and successor Khosroo Nooshirvan is celebrated by the Persian historians as a model of justice, generosity, and sound policy. He ascended the throne A. D. 531. He is said to have been the fruit of a casual amour of Kobad, who, flying from his brother Ferose, then established on the throne, halted for a night with a beautiful girl at Nishapore. Four years afterwards, on his return to that city, his fair mistress presented him with a boy, who was one day to reign so gloriously on the Persian throne. His first care after his accession to the sovereignty was to extirpate the pernicious sect of Mazdak, encouraged by his father, one of whose leading tenets was a community of property and of women. He had recourse to severe measures. The founder of the sect and many of his followers were put to death; and the women and property which they had appropriated were restored to those to whom they belonged. He was indefatigable in promoting the prosperity of his dominions, in building and repairing bridges, in restoring and repeopling decayed towns and villages, in founding schools and colleges, and in giving every degree of encouragement to learned men, and even to the Greek philosophers who resorted to his court. His empire was divided into four great governments, namely, 1*st*, Khorassan, Seistan, and Kerman; 2*d*, the lands dependent on the cities of Ispahan and Koom, the provinces of Gheelan, Azerbijan, and Armenia; 3*d*, the provinces of Fars and Ahwaz; and 4*th*, Irak, which extended to the frontier of the Roman empire. A well-digested system of provincial government was introduced into those provinces, and every check adopted that could prevent the abuse of power. He imposed a fixed and moderate land-tax over all his dominions, and a capitation-tax on the Jews and Christians; and the strictest regulations were adopted for preserving the discipline of his army. The reign of Nooshirvan was illustrated as well by his conquests abroad as by his wise policy at home. He compelled Justinian to conclude a disgraceful peace at the price of 30,000 pieces of gold; and the reduction of Syria, the capture of Antioch, and the advance of the Persian armies to the shores of the Mediterranean, attest his triumphant reign. Though he was checked in his career of conquest towards the west, yet his sway was finally extended over the countries beyond the Oxus, over those to the south of the Indus, some provinces of India, and the finest districts of Arabia. He reached the advanced age of more than eighty years.

Hoormuz III. the Chosroes of the Greeks, was declared the successor of Nooshirvan his father. His administration was wise and prosperous for a time, whilst he acted under the advice of his preceptor; but on the death of the latter, he fell into every excess, and, after a short and disastrous reign, was dethroned and put to death by one of his generals, Baharam Choubeen, who usurped the supreme authority. But Khosroo Purveez (Hormisdas), the son of the late king, flying to the Roman emperor Maurice, his adopted father, was, by his assistance, reinstated in the throne, and Baharam was forced to seek refuge amongst the Tartars, whose armies he had formerly defeated, and amongst whom he died. The new monarch showed his gratitude to the Roman emperor by scrupulously fulfilling all the engagements he had contracted with him. He surrendered Dara and several other strong places on the frontier, and, besides, sent him costly presents. But no sooner did he hear of the death of Maurice, than he invaded the Roman territories with a large army; pillaged and destroyed Dara, Mardin, Edessa, and Amida; laid waste Syria; took the holy city of Jerusalem; and set on fire the magnificent churches of St Helena and Constantine. The true cross, which had been enclosed in a golden case, and buried deep in the earth, was discovered and borne in triumph to Persia; and a crowd of captive priests and bishops swelled the train of the conqueror. Egypt was added to his other conquests; his troops entered Alexandria in triumph; and, after carrying his victorious arms westward to Carthage and Tripoli, and finally extirpating the Greek colonies of Cyrene, he returned in triumph through the sands of the Libyan desert. In the same campaign another army advanced from the Euphrates to the Thracian Bosphorus; and, after taking Chalcedon, his victorious troops remained encamped for twelve years in the vicinity of Constantinople. But, whilst his general and his armies were thus gaining laurels in the field, Khosroo was indulging at home in the most unheard-of luxury. Every season a splendid palace was raised; and his thrones were made of the most exquisite materials, one being formed to represent the twelve signs of the zodiac and the hours of the day. His treasures; his wives, amounting to 12,000, besides the incomparable Shereen, of whom he was passionately fond; his horses, amounting to 50,000; his Arabian charger of surpassing fleetness; and his musician Barbud; furnish inexhaustible topics for the pen of the historian, and for the hyperbolical praises of his countrymen. But his reign, hitherto glorious, was, towards its termination, closed with misfortunes. Herodius, the Roman emperor, alike remarkable for luxury and indulgence in the palace and for valour and military skill in the field, was roused to a sense of the public danger by the victories of Khosroo, and with a powerful army suddenly invaded Persia. In the course of six years, he succeeded in stripping the Persian king of all his foreign conquests; he defeated his armies in every encounter; marched without opposition into the heart of his country; destroyed his splendid palaces, and plundered his hoarded treasures. His subjects, headed by his own son, at last rebelled against him, and put him to death, after a reign of thirty-eight years. Persia, after the death of this prince until the accession of Yezdijird III. (the Isdigertes III. of western writers), was a scene of confusion and misery, from the combined evils of famine, the contentions of the nobles, a succession of weak sovereigns, or rather, as Sir John Malcolm terms them, pageants of power, and from the threatened attack of the Arabian tribes, who, under the standard of the Mahommedan faith, had now become very formidable to all surrounding states. In their first attacks on the Persians, the Moslemin armies were repulsed, and their leader Abu Obeid was slain. The Arabs, reinforced, were again defeated by Mehran the Persian general. But in another action the Persians were defeated, and their general slain. Yezdijird, who was now elevated to the throne, was the last hope of the sinking state. An ambassador was sent to him from the Arabian tribes, proffering peace on condition that he should accept of their religion, and pay the taxes which all believers are bound to pay. These terms were rejected with disdain. Great armies were now assembled on both sides; they met on the plains of Nahavund, A. D. 641, where the Mahommedans gained a remarkable victory, that for ever decided the fate of Persia. Of the Persians 30,000 perished on the field, and 80,000 more were drowned in a deep trench which surrounded the camp. Persia, from this date, fell under the dominion of the Arabian caliphs. Yezdijird, the last monarch of the Sassanian line, fled from the field of battle to Seistan, to Khorassan, and lastly to Merv, from which being also forced to fly, he concealed himself in a mill eight miles distant. But the miller, tempted by his rich robes and armour, murdered him whilst he slept, and thus ended, A. D. 651, the dynasty of the Sassanides, and the idolatrous worship of the Magi, which had existed in Persia for 1200 years.

After the flight of Yezdijird, the armies of Persia, scattered and discouraged, were able to oppose only a feeble resistance to the hardy children of the desert, skilfully commanded, and, besides, inflamed by a fanatic enthusiasm; and in a short time, accordingly, they very soon overran and laid waste the whole country, with a bigoted fury that had no parallel, sparing neither sex nor age, and subverting in one common ruin the laws, manners, and most sacred institutions of the country. Many were contented to purchase life by embracing the new faith; and others fled to the mountains and fastnesses of the country, or to a distant land. "The progress of the conquerors," says Sir John

Malcolm, "was rapid and wonderful; colonies from the burning deserts of Arabia were extended over the cold countries of Khorassan and Balkh; and they flourished on the soil to which they were transplanted.[1]" The conquest of the country being completed, it was divided into different provinces, over which lieutenants were appointed; and it was thus held for more than two centuries under the dominion of the caliphs. But this system of provincial authority terminated, as usual, with the declining energy of the supreme power, in destruction and anarchy in its subordinate parts. The caliph at Bagdad, from the head of a powerful and warlike tribe, had degenerated into a mere pageant; and as the bonds of authority were relaxed, the different rulers and chiefs of provinces began to throw off their allegiance, and to aspire to independent power. The caliph was merely reverenced as the supreme pontiff; his governors used his name in their public prayers; they were nominally his vassals; but they held the substance, and he had only the shadow, of political power. The sceptre, which was feebly held by the successors of Omar and Ali, presented a tempting prize to aspiring ambition; nor, in the distracted state of the country, was it long before it was claimed and won by an adventurer from the lowest ranks of life. Yacoob-ben-Leis was the son of a pewterer of the name of Leis, in Seistan. He worked, when young, at his father's trade; but he was prodigal of his money; and, tempted by his necessities, he became the leader of a bold and desperate band, which gradually increased with the success of his enterprises. He soon attained power and consideration; and his aid was solicited by Salah-ebn-Naser, the ruler of Seistan, against his fellow-ruler of Khorassan. He was afterwards raised to be commander of Salah's army; and the first use he made of his power was to seize on the chief who had conferred it on him, and to send him to Bagdad; a service for which he claimed and received the government of his native province, as the servant and lieutenant of the faithful. He afterwards took the important fortress of Herat, reduced the province of Kerman, marched thence to Shiraz, and finally made himself master of the greater part of Persia. The caliph, secretly dreading his power, sent him a formal investiture of certain territories as governor, which he rejected with disdain. "Tell your master," said he to the envoy, "I am already indebted to my sword for what he so generously bestows upon me. Let him keep the investiture for some person who will own the obligation, and who is disposed to question my title." He was afterwards engaged in open war with the caliph, when he was overtaken by disease, and died, in 877, leaving almost the whole kingdom of Persia to his brother Amer, who reigned twenty-three years, but was defeated and taken prisoner by Ismail, a Tartar chief with whom he was at war, and, being sent to Bagdad, was there executed. With Amer fell the fortunes of his family; and though two more princes maintained a precarious authority, the empire of Persia was divided between two families, the Samanee and Dilemee. The power of the first extended over Khorassan, Seistan, Balkh, and the countries of Transoxiana, including the cities of Bukharia and Samarcand. The Dilemee princes exercised sovereign power over the greater part of Irak, Fars, Kerman, Kusistan, and Laristan. Of the first-named dynasty Osmael was the most celebrated. His grandfather was a Tartar chief of the name of Saman, who claimed descent from Baharam Choubeen, the Sassanian. He extended his conquests both eastward and westward, and died in 907, at the age of sixty. Asia was at this time the scene of great political revolutions, in the course of which adventurers arose from the lowest ranks; and, having gradually increased their followers, at last acquired sovereign power. It was one of these fortunate chiefs, Abustakeen, that laid the foundation of the great empire of Mahmood of Ghizni. He was one of the chiefs of Bukharia, who having renounced his allegiance to that court, retired to Ghizni with such followers, amounting originally to seven or eight hundred, as he could collect, and there laid the foundation of a petty principality. His son Isaak succeeded him; but he reigning only a short time, the supreme power by unanimous consent was given to Sabactageen, a man of Turkish descent, who, according to some, had been purchased as a slave by Abustakeen, whilst others state, and with more probability, that he was one of the royal guards. He extended his empire by conquest; and when he died, his kingdom extended from Khorassan to the Punjab. Ismail, his younger son, succeeded; but his ambitious brother soon wrested the sceptre from his feeble hand. Ameer Noah, the fifth monarch from Ismail, being hard pressed by his nobles, applied for aid to Sabactageen, who sent his son Mahmoud with an army that overthrew the rebels, and the young prince obtained as a reward the government of Khorassan. Such was the commencement of that great empire of Mahmoud of Ghizni in Persia, which in a few years stretched from Bagdad to Kashgar, and from Georgia to Bengal, and which rose on the ruins of many other subverted empires. He was an enterprising and active prince; and was distinguished by his fanatical zeal, which impelled him to the invasion of India, from which he brought back an immense spoil, valued at twenty millions of dirhems (L.458,333 sterling), 53,000 captives, and 350 elephants, besides jewels to a vast amount. This conquest of India was marked by the wildest rapine and devastation; and his zeal was especially signalized by breaking down and destroying all the idols and splendid temples which were dedicated to idolatry. He died in the year 1208, in a magnificent edifice, to which he had vainly given the title of the "palace of felicity." He was succeeded by Musaood, who was defeated by the Seljuk Turcomans in Khorassan; and in the succeeding reign of Madood, the house of Ghizni lost the whole of their Persian dominions. These Tartar tribes were numerous and powerful; they were a nation of shepherds, inured to fatigue, to long marches, and to every kind of hardy exercise, and trained from their infancy to the use of arms. Their numbers and discipline enabled them easily to overpower the civilized inhabitants of more fertile countries. Accordingly, in the year 1042, the Tartar tribes subdued Khorassan; and their sovereign Togrul Beg, chief of the tribe of Seljuk, assumed in 1389 the state of a sovereign at Nishapoor. In the succeeding twenty years he overran all Persia, made himself master of Bagdad, and took prisoner the sovereign pontiff, the commander of the faithful. He approached him, however, with every outward mark of reverence, and was constituted the temporal lieutenant of the eastern and western divisions of the empire. This alliance was farther cemented by a marriage with the daughter of the caliph. But Togrul Beg, who had by this time attained to his seventieth year, died a few months after the marriage. He was succeeded by his nephew Alp Arselan, the Valiant Lion, who has been praised by all historians for his justice, valour, and generosity. He successfully defended his dominions against an invasion by the Romans; defeated their armies; and having made their emperor prisoner, generously set him at liberty for a fair ransom. He was killed by a rebellious chieftain whom he had ordered to be put to death, but who, having shaken off his guards, assailed him on the throne with all the fury of despair. Alp Arselan, an unerring archer, seized his bow, and commanded his guards to stand aloof; but for the first time his arrow missed its mark, and he fell under the assassin's stroke.

The celebrated Malik Shah, his son, succeeded to the throne; and his reign rivalled, and even surpassed, in glory that of his father. Syria and Egypt were subdued by his victorious generals; Bukharia, Samarcand, and Khauresm yielded to his sway; and he received homage and tribute from the tribes beyond the Jaxartes, and from the distant country of Kashgar. Including the territories of all those princes whom he had conquered, and obliged to do him homage and to pay tribute, his dominion extended from the Mediterranean to the wall of China, and prayers for his prosperity were offered up at the same time in the cities of Jerusalem, Mecca, Medina, Bagdad, Ispahan, Rhe, Bukharia, Samarcand, Ourganjee, and Kashgar. Malik Shah was celebrated as a great and a good prince; the only exception to which is his treatment of Nizam-ul-Mulk, the old and veteran minister of his father and himself. Giving ear to the calumnies of his enemies, he disgraced this faithful councillor, who was soon afterwards stabbed by an assassin hired for this purpose by his successor in office, from a fear of any favourable change taking place in his master's sentiments. Malik Shah survived his minister only a few months, being seized with a violent illness, which terminated his life, in his thirty-eighth year. "The country of Persia," says Sir John Malcolm, "was greatly improved during his reign; many colleges and mosques were built; and agriculture was promoted by the construction of canals and water-courses. Learning was also encouraged; and an assembly of astronomers from every part of Malik Shah's wide dominions were employed for several years in reforming the calendar; and their labours, which established the Jellalean or glorious era, is a proof of the attention which was given at this period to the noblest of all sciences." For thirty years after the death of Malik Shah, Persia was distracted by the wars of his four sons, who contended for the supreme power; but Sanjar, having at length triumphed over his competitors, was elevated to the throne. His reign was for a time successful and prosperous. He resided in Khorassan; and from this spot, as from a centre, his dominion extended in one direction beyond the Indus, and in another to the Jaxartes. Towards the latter end of his reign he experienced the most signal reverses of fortune. Advancing into Tartary, he was completely defeated by the monarch of Kara Khatug, his family were made prisoners, and all his baggage was plundered. He afterwards marched against the Turcoman tribe of Ghuz, who had refused their royal tribute, and in a decisive action which ensued he was defeated and taken prisoner. After being long detained, and cruelly treated, he made his escape, and returned to his own country, where the spectacle of his wasted dominions, ravaged and destroyed by barbarous invaders, so preyed upon his spirits, that he died of melancholy in 1175, at the age of seventy-three. After his death Persia continued during forty years distracted by the wars between different branches of the Seljookian dynasty. The last who exercised sovereign power was Togrul III., who was slain by the monarch of Khauresm, as he went into battle flushed with wine.

---

[1] History of Persia, vol. i. chap. viii.

With this prince terminated the race of the Seljookian monarchs in Persia, who from the commencement of the reign of Togrul I. had ruled 158 years. From the decline of this dynasty to the conquest of Persia by Hulakoo Khan, the son of the great conqueror Genghis, the country was distracted by the contests of these rival chiefs, who are known under the name of Atta-begs. They were petty princes, who taking advantage of the weakness and anarchy which prevailed, extended their authority over some of the finest provinces of the country. A detailed account of the progress and decay of these various dynasties would exceed our limits; nor would it contain either amusement or instruction. But there is one chief who requires to be noticed, who may be said to have been the head of a band of assassins devoted to his purposes, and by means of whom he caused the most powerful sovereigns to tremble, and spread far and wide the terror of his mysterious power. His followers were reckoned at 50,000; they were called mysterious and devoted; and each was bound, under the most dreadful sanctions, to sacrifice, at the command of their chief, either his own life or that of another. Hussun Subah was the first of these chiefs. He had been mace-bearer of Alp Arselan; but being displeased with his minister Nizam-ul-Mulk, he retired to Rhe, and afterwards to Syria, where he entered into the service of a chief of the family of Ismail, and adopted their views concerning the right of the descendants of Ismail to the holy dignity of Imaum, instead of the younger brother of Ismail. He afterwards returned to Rhe, his native place, where, leaguing himself with other mal-contents, he succeeded in gaining possession of the mountain fort of Allahamaut, whence he commenced a series of depredations on the surrounding country. Malik Shah Seljookee sent a force against him, which was repulsed. He was soon afterwards exposed to a more serious attack from the Sultan Sanjar, who resolved to extirpate a race whose murders and depredations spread terror over his kingdom. But he was warned to desist from his fatal project, by secret threats of assassination. He had made some marches in the direction of Allahamaut, when one morning as he awoke he discovered a poniard stuck in the ground close to his bed-side, and read with surprise, written on the handle, "Sultan Sanjar, beware. Had not thy character been respected, the hand that stuck this dagger into the hard ground could with more ease have plunged it into thy soft bosom." The warrior who had often faced death in the field of battle trembled at this mysterious threat; and it is certain that he desisted from his meditated attack. Hussun Subah brought several other hill-forts under his sway; and was styled "chief of the mountains," or, as his Arabic title has been erroneously translated, "the old man of the mountain," the name by which he and his descendants are distinguished in the European histories. Caliphs, princes, and nobles, fell under the blows of these assassins; and the power and dominions of Hussun Subah were handed down through a series of sovereigns who ruled for 170 years, the terror and disgrace of Asia, and who in 1256 were finally extirpated by the overwhelming and victorious armies of Hulakoo Khan, who rivalled his sire in the rapidity of his conquests. His first design was to turn his arms against the declining empire of the Greeks; but he was diverted from this object by an astrologer, who directed his hostility against Bagdad, the seat of the caliph's authority. This place was speedily stormed by the Tartar armies, and its inhabitants were put to the sword; the Caliph Mustasim, with his only surviving son, were slain; and thus was for ever extinguished the celebrated empire of the Arabian caliphs. The conquest of Persia, Mesopotamia, and all Syria, was achieved by Hulakoo in the same year, who meditated other ambitious schemes of conquest in the East. But the defeat of his army in Syria by the prince of the Mamelukes in Egypt compelled him to abandon his design; and having restored his affairs in Syria, he fixed his residence at Maragha, a beautiful town of Azerbijan, where he spent his declining years in the cultivation of letters and philosophy. He built an observatory on the summit of a mountain, the foundation of which still remains, "and where," says Sir John Malcolm, "his favourite, Nasser-u-Deen, formed those astronomical tables which have become so celebrated under the name of the tables of Eel-Khannee," and are still referred to for the latitude and longitude of such places as are not fixed by European observations. He was succeeded by Abaku-Khan in the year 1264, who was anxious, by cultivating the arts of peace, to repair the ravages of war, and to heal the still bleeding wounds of his wasted empire. He was assailed from the east by the powerful armies of Tartar chiefs; but he succeeded in repelling all their attacks, and in maintaining the integrity of his empire. He died, it is supposed, by poison, in the year 1281. The Mogul lords having held a council, raised to the throne his brother Neckandar, who, though he was baptized in his youth, afterwards renounced the Christian faith, which he persecuted with all the violence of a renegade, and assumed the name of Ahmed Khan. But his persecution of the Christians was so obnoxious to his own subjects, that they conspired against him, and deprived him both of his crown and of his life. Arghoun, his nephew, whom he had thrown into prison, was raised to the throne by the Mogul nobles, but did not assume the name until he received the investiture from the emperor of Tartary, by whom he was hailed as sovereign of Persia, Arabia, and Syria. His reign was marked by no event of any consequence; and on his death, which occurred in 1291, his brother Key Khaton was raised to the throne by the majority of the Ameers. The latter was indolent, sensual, and extravagant; and his short and inglorious reign would hardly merit notice, were it not for an attempt by an officer of the revenue department, of known talent, to introduce a paper-currency, in order to supply the means of royal extravagance. But credit, the foundation of paper-currency, cannot exist under a despotism which affords no security either for life or for property. The scheme was therefore altogether vain, and appears to have been the device of a tyrant for cheating or plundering his defenceless subjects. From this period until the conquest of the country by Timour or Tamerlane, the history of Persia presents one continued scene of intestine commotion; subordinate chieftains contending for dominion, distraction and violence everywhere prevailing, and the country sinking under the ruthless devastations of war. It is in scenes of trouble and revolution such as these that ambition finds scope for its daring schemes, and that genius, emerging from obscurity, rises, in spite of every obstacle, to its high destiny. Timour the Tartar, or Tamerlane, a corruption of Timour-lung, or Timour the Lame, an appellation derived from an obvious bodily defect, was descended from Korachar Nevian, who had been vizier to Chaghtai the son of Genghis, and also claimed kindred with that great conqueror. The early years of Timour were passed amidst danger and difficulty; and it was in that school that he acquired those qualities which raised him to the sovereignty of the world. He was counsellor and general to the Tartar prince, Ouleaus Khajah, who ruled over the territories between the Oxus and the Jaxartes. But having soon thrown off his allegiance to this prince, he led a wandering life, with only a few faithful followers, enduring hardships and peril, yet never yielding to despair. He had formed a close alliance with Ameer Hussein, one of the most powerful nobles of Transoxiana. Their joint object was to expel the enemies of their country; and Ouleaus, though he had conquered in the field, having been forced to retire with disgrace from the siege of Samarcand, the countries between the Jaxartes and the Oxus were freed from the foreign enemy. A war for the possession of Transoxiana now ensued between Timour and Hussein, and was only interrupted by a short and hollow peace, which terminated in the overthrow of Hussein, who was taken prisoner, and, as is generally believed, put to death, with the secret sanction or by the orders of his rival. Eleven years elapsed before Timour had fully reduced to tranquillity his newly-acquired dominions, and had extended his power over Kashgar and Khaurezm; after which his whole reign was one unvaried course of the most triumphant success. Victory everywhere attended his arms; he subdued cities and kingdoms; strongholds hitherto deemed impregnable yielded to his power; and the devoted countries through which he passed were given up to slaughter and devastation, their towns being sacked, the defenceless people savagely massacred, and vast pyramids of heads raised up as the trophies of his victories. He subdued Khorassan, Candahar, and Caubul, and laid the two latter cities under heavy contributions. He invaded Persia, which, being now ruled by the degenerate descendants of Hulakoo, was entirely barren and wasted. He extended the limits of his empire to the farthest bounds of Tartary; and whilst one body of his troops spread dismay to the wall of China, another army penetrated to the banks of the Irtysch, and a third to the Volga. Timour next marched against Bagdad, which he stormed, and also took the remarkably strong fortress of Takreet; after which his vast armies were dispersed over Asia Minor, Mesopotamia, Kurdistan, and Georgia. He afterwards invaded Russia, and advancing to Moscow, took and plundered that city. Returning to his own country, he prepared for the invasion of India, a particular account of which would be a mere detail of burning and massacre. His war with Bajazet, and his defeat and capture of that warlike chief, were amongst the latest exploits of his active reign; and he had embarked on the arduous enterprise of the conquest of China, when he was arrested by an enemy which he could not conquer. He was seized with a violent illness at the city of Otrar, where he expired in 1405, declaring Peer Mahommed Jehangheer his successor. The latter, however, had a competitor for the crown in Khuleel Sultan, his cousin, by whom he was deposed and murdered; and, in his turn, Khuleel, infatuated by his attachment to the beautiful Shad-ul-Mulk, on whom he squandered the vast treasures of Timour, was deposed by the nobles.

He was attached to the arts of peace, a philosopher, a man of science, and a poet; and his whole care was to heal the wounds inflicted on his country by the wars of the former reign. He rebuilt Herat and Merv, and drew around A.D. 1446. him from all quarters men of literature and science. Sultan Shah Rokh, uncle of Khuleel Sultan, hearing of the misfortunes of his nephew, marched from Khorassan, and his authority was acknowledged over all Transoxiana. Khuleel Sultan was succeeded by Ulugh Beg, who also followed the arts of peace, and neglected those of war. He was deposed and put to death in the year 1449, by his son Abdul Lateef, who was slain by his own soldiers within the short period of six months. The Mogul dynasty in Persia was now fast verging to decay, and its final extinction was preceded, as usual, by scenes of confusion and civil war. The kingdom was at length divided amongst three sovereigns, viz. Sultan Hassein Mirza, a descendant of Timour, who kept a splendid court at Herat, and governed Khorassan; Kora Yussuf, the Turcoman chief of the Black Sheep (the tribes of the Black and White Sheep being so called from their carrying the figures of those animals on their respective standards), ruled over Azerbijan, Irak, Fars, and Kerman; and Uzun Hussoun, chief of the Turcomans of the White Sheep, who finally acquired possession of all western Persia, and attacked the Emperor Mohammed II., from whom he sustained a severe defeat. After his death A.D. 1468. the country was distracted by the contentions of his sons, grandsons, and nephews, for the supreme authority; and their dissensions, whilst they accelerated their own ruin, prepared the way for a native dynasty, which was gladly A.D. 147 hailed by the people as the auspicious omen of domestic peace.

Shah Ismail was the first monarch of the Suffavean line. He traced his descent from Moosa Kauzim, the seventh imaum. The first of the family who attained to any celebrity was Sheik Suffee-ul-Deen, who resided in the town of Ardebil, and from whom the dynasty takes its name of Suffavean, or Suffyean. His son Sudder-ul-Deen inherited all the sanctity of his sire. The great conqueror Timour even condescended to visit him in his cell, that he might receive his blessing; and on his asking whether he, Timour, could do aught for his comfort, "Give up," replied the saint, "those Turks whom thou hast carried off as captives." The disinterested request was granted, the saint was dismissed with presents, and the descendants of these captives ever afterwards acknowledged their gratitude by their ardent support of the Suffavean dynasty. The immediate descendants of Sudder-ul-Deen, Khaujah Ali, Juneyd, and Hyder, acquired also a great reputation for sanctity. The first, after making the pilgrimage to Mecca, visited Jerusalem, where he died. His grandson Juneyd assumed the sacred mantle or patched garment worn by the Suffee teachers, after his father's death; and so numerous were his disciples, that Kara Koinlu, who at that time ruled in Azerbijan, took the alarm, and banished him from Ardebil. He returned to Shirwan, where he was killed by an arrow in a conflict with the troops of that province. He was married to a sister of Uzun Hussoun, chief of the Turcomans of the White Sheep; and this lady was the mother of Sultan Hyder, who succeeded him, and became a warrior as well as a saint. His uncle Uzun Hussoun gave him his daughter in marriage, by whom he had three sons, Sultan Ali, Ibrahim Meerza, and Sultan Shah Ismail. Hyder was defeated and slain in an attack which he made on the province of Shirwan in order to revenge his father's death. Sultan Ali succeeded; but he and his brothers were seized at Ardebil, by Yakub, one of the descendants of their grandfather Uzun Hussoun, who had become jealous of their influence, and confined in a fort, where they remained prisoners for four years. They afterwards made their escape, and were soon joined by numerous adherents. But in the mean time they were attacked, Sultan Ali was slain, and his brothers fled in disgrace to Gheelan, where Ibrahim Meerza died. These events occurred during the infancy of Ismail, the third son of Hyder, of whom we know little till he attained the age of fourteen, when he collected his adherents, and marched against the great enemy of his family, the ruler of Shirwan, whom he defeated. Alwund-Beg, a prince of the dynasty of the White Sheep, hastening with his troops to crush the young warrior, shared the same fate; and the triumphant prince having made himself master of the province of Azerbijan, fixed his residence at Tabriz. Next year he vanquished Sultan Mourad, one of the military competitors for supreme dominion in Persia; and in less than four years from his leaving Gheelan he was acknowledged the sovereign of Persia.

A. D. 1502. Shah Ismail, not being born the chief of a tribe, had no hereditary feuds to avenge; his family were objects of hostility to no one; and he united in his person the reverence and affection of all his subjects. He was a firm adherent of the Sheahs, and of the title of Ali to the caliphate after his uncle Mahommed's death, pitying his misfortunes, and hating with pious zeal, as usurpers of the caliphate, Abubekr, Omar, and Osman, the three first successors of the Prophet, and all their Soonee followers. The Turkish tribes to whom he owed his elevation were highly honoured. They were distinguished by a red cap, from which they received the name of Kuzzilbash, or golden heads, which has descended to their posterity. Persia, Khorassan, Bagdad, and Balkh, submitted to his arms. His territories were afterwards invaded by Sultan Selim about the year 1514, with a numerous and well-disciplined army. In the action which took place, the Persian monarch, after performing prodigies of valour, was entirely defeated, which affected him so deeply that he was never afterwards seen to smile. After the death of Selim he crossed the Araxes, wrested Georgia from the possession of Turkey, and died at Ardebil in the year 1523. He was succeeded by his son Tamasp, who ascended the throne when he was only ten years of age. His reign, which continued fifty-three years, proved prosperous. He repelled the invasions of the Uzbecks on the east, and of the Ottomans on the west. It was from him that Humaiun, emperor of India, when he fled from his rebellious subjects, received the aid which enabled him to regain his throne. It was to him also that Elizabeth sent her envoy, Anthony Jenkinson. But the intolerance of the Mahommedan monarch could not brook the presence of a Christian. His family was numerous; and after several years of disputed succession, and of brief and troubled reigns, Abbas his grandson was proclaimed king in 1582, when a minor. During the earlier years of this monarch's reign, the country was alternately alarmed by internal disturbance and foreign aggression, each party in their turn using the name of the sovereign. But as he advanced to manhood he vindicated his rights, and in the course of three years he reigned the A. D. 15 undisputed sovereign of the country. His reign, which lasted forty-three years, was highly successful and glorious. He was engaged in wars with the Turks and with the Uzbecks, whose armies he defeated in several actions; and it was during his time that an amicable intercourse commenced between Persia and Europe.

Sir Anthony Shirley, a gentleman of family, was persuaded by the Earl of Essex to repair to the court of Persia; and, with twenty-six followers, gallantly mounted and richly attired, he presented himself to the king, who received him with every mark of distinction. The military skill of these foreigners enabled him to discipline his army and to improve his artillery, so that with an army of 60,000 warriors he obtained a decisive victory over 100,000 Turks. In this battle, which was fought on the 24th of August 1605, Sir Anthony Shirley was thrice wounded. After the battle, as Shah Abbas was resting on the field, a man of uncommon stature and of a soldier-like appearance was led past by a youth, who had just made him prisoner. The king having asked who the captive was, the latter replied, "I belong to the Kourd family of Mookree." An officer of the house of Mookree in the service of the king had a bloody feud with the family of the prisoner, and the king commanded the captive to be delivered to him. The officer, however, refused to receive him. "My honour," he said, "calls for blood; but I have made a vow never to take advantage of an enemy who is bound and in distress." The king, irritated by this noble speech, which was a reproof to himself, called to the captain of the guards to strike off the head of the prisoner. The gigantic Kourd immediately broke the cords by which he was bound, drew his dagger, and rushed upon the king. A fierce struggle ensued, in which all the lights were extinguished, and in the darkness no one dared to strike. At last the king exclaimed, "I have seized his hand; I have seized his hand." Order was restored, and lights being brought, the unfortunate captive was pierced by a hundred swords. This victory gave a decided check to the Turks, who were driven from Azerbijan, Georgia, Koordistan, Bagdad, Mosul, and Diarbekir, all of which were re-annexed to the Persian empire. This monarch also entered into an alliance with the English for the destruction of the flourishing Portuguese settlement of Ormuz, which unhappily proved but too successful; and this place, long renowned as the seat of wealth and a great commercial emporium, was plundered and left to decay. Extravagant hopes were entertained in England of the great wealth which was to be derived from a commerce with Persia, and other embassies were fitted out and despatched to the Shah. But these hopes were not realized; nor did they rest on any better foundation than the fanciful descriptions given of these eastern countries by European travellers.

Abbas, considered as an eastern king, may be termed enlightened, and anxious for the good of his subjects. He expended his revenues in the improvement of his dominions, and erecting caravanserais, bridges, aqueducts, bazaars, mosques, and colleges; he embellished Ispahan his capital, and Amshed; and he built splendid palaces, the ruins of which still attest his taste and magnificence. He was also distinguished by his toleration, especially to Christians; and he was liberal in his foreign policy, though his treatment of the inhabitants of Georgia, who were violently transplanted from one district to another, without any regard to their convenience or feelings, was tyrannical in the extreme. He indulged freely in the use of wine, yet he affected extreme piety, every year making a pilgrimage to some particular shrine. To his family he proved a sanguinary tyrant. He had four sons, whom he caressed, whilst in infancy, with parental fondness, but who, as they arrived at manhood, were viewed with jealousy and hatred. The oldest son was assassinated, and the eyes of his other children were put out, by his orders. One of these, Khodahbundah, shut out from the light of day, wandered about gloomy and desperate, brooding over schemes of vengeance against his most unnatural father. He had a daughter, Fatima, innocent and lovely, and the delight of her grandfather, who could not endure that she should be out of his sight. The prince, learning the fondness of his father for this his child, seized her one day with all the fury of a maniac, and deprived her of life. He next directed his frantic fury against his son, who was carried away by the distracted mother. The rage and despair into which Abbas was thrown by the death of his granddaughter gave a momentary joy to the son, who concluded this bloody tragedy by swallowing poison. Abbas died soon afterwards, in 1628, at the age of seventy, worn out with affliction of mind.

By the desire of the expiring prince, Sam Mirzam, one of the sons of Suffee, who had been murdered, was placed on the throne, which he occupied fourteen years. His son Abbas II. succeeded him at the age of ten, and reigned prosperously twenty-five years, though his habits were licentious and intemperate. He was succeeded by his eldest son Abbas in the year 1641, who, under the title of Shah Solyman, reigned twenty-nine years. He was, like his father, the slave of dissolute habits; and his drunken orgies were often stained with blood. He was succeeded by Hussein Mirza, a weak prince, who was ruled by eunuchs and priests, and whose measures tended to destroy the little spirit which yet lingered amongst the nobles and chiefs. The first twenty years of his reign passed over in tranquillity, but it was only the prelude to a political storm. The Afghan tribes who inhabit the mountainous tract between Khorassan and the Indus had long been subject to Persia, and having often suffered great oppression, at length broke out into rebellion, irritated by the tyranny of Gurgeen Khan. The insurgents were headed by Meer Vais, an Afghan chief. They invited the obnoxious governor Gurgeen Khan to a feast, where he was suddenly attacked and put to death; and Meer Vais, collecting his followers, surprised and stormed the fortress of Candahar. He then proceeded to strengthen himself in his newly usurped power. Whilst the weak monarch endeavoured by negotiation to pacify this formidable insurgent, Meer Vais imprisoned his ambassador, and set his power at defiance; and a second ambassador met with no better treatment. The court of Persia now assembled an army under the command of Khusru Khan, who advanced against Meer Vais, defeated his army, and laid siege to Candahar. The insurgent chief having assembled another army, compelled the Persian general to raise the siege of that place, and afterwards defeated him in a decisive action, in which he was slain. In the midst of his successes Meer Vais died, and was succeeded by his brother Meer Abdallah, who was assassinated by Mahmoud, son of Meer Vais. The troubles which now afflicted Persia on every side gave ample leisure to Mahmoud to mature his plans, and to consolidate his power. The Uzbecks were ravaging Khorassan; the tribes of Kurdistan were almost at the gates of Ispahan; the Abdallee Afghans had taken Herat, and afterwards Mushed; the islands in the Persian Gulf had been subdued by the Arabian governor of Mascat; and the rude tribes of Georgia had attacked Shirwan, and plundered Shamachie. A prediction by an astrologer, of the total destruction of the capital by an earthquake, completed the public dismay, when intelligence was received that Mahmoud Ghiljee had entered the country at the head of 25,000 Afghans. He was met by the royal army of 50,000 troops; and an action took place, which ended entirely in favour of the Afghans. The consequence was the siege or blockade of Ispahan, which, after enduring all the miseries of famine, surrendered on the 21st of October, after a siege of seven months. The following day the fallen monarch of Persia, Hussein, took a solemn leave of his subjects, and signed a capitulation, by which he resigned the crown to Mahmoud. He proceeded, attended by a train of nobles, and by 300 troops, towards the Afghan camp; and being permitted, after some delay, to proceed to the palace of Ferrahabad, he was introduced into a great hall or saloon, where he found the conqueror seated. He addressed him in the following words. "Son, since the great sovereign of the universe does not will that I should reign any longer, and the moment has come which he has appointed for thy ascending the throne of Persia, I resign the empire to thee. May thy reign be prosperous." He then presented the royal plume of feathers, which he took from his turban, to the vizier of Mahmoud; but that prince refusing to accept it from any other than the monarch to whom it belonged, the humbled prince now took it from the minister, and placed the emblem of royalty in the turban of his enemy, who all the while retained his seat, and exclaimed, "Reign in peace." After the usual refreshments of tea and coffee, Mahmoud addressed his captive. "Such," said he, "is the instability of human grandeur. God disposes of empires as he pleases; he takes them from one to give to another; but I promise ever to consider you as my father, and to undertake nothing without your advice."[1] Hussein, with his nobles, after doing homage to the Afghan sovereign, was confined for seven years in a small palace, when his enemies, threatened with a reverse of fortune, caused him to be assassinated; and in his person may be said to have terminated the Suffavean dynasty, as his son Tamasp, though he assumed the title of king, never possessed any real power, and only struggled a few years against his inevitable fate.

Mahmoud having thus succeeded in acquiring the sovereignty of Persia, now endeavoured to conciliate the people whom he had subdued. But the Persians hated the Afghan yoke; and, as they recovered from their first dismay, they began to attack and to cut off scattered parties of the invaders. At the same time Persia was invaded both by Russian and Turkish armies. The Russian army advanced into the country and took possession of Derbend, and the Turkish army was already on its march to Hamadan, when the inhabitants of Kazreen rose in insurrection, and expelled the Afghan garrison from the place. Mahmoud was now seriously alarmed. The probable revolt of the capital seemed to be the most immediate danger; and his gloomy mind, alarmed and enraged by these signs of vengeance, conceived the horrible design of exterminating the conquered people. He commenced with the massacre of three hundred nobles and their children, who were treacherously invited to a feast. He afterwards put to death three thousand of the late king's guards, whom he had taken into his pay; and at length every person who had

[1] Sir John Malcolm's History of Persia, chap. xv. p. 343.

Persia. been in the service of Shah Hussein was included in one bloody proscription, and put to death without mercy. For fifteen days the city of Ispahan was one scene of blood, and the spirit of the people was so broken under this unheard of tyranny, that one Afghan might often be seen leading three or four Persians to execution.

After this, Mahmoud, being aided by the Kurdish tribes, succeeded in making himself master of some of the principal cities of Irak and Fars. But his affairs appeared to be on the decline; his kingdom was threatened from various points, and his mind proved at last unequal to the difficulties with which he was assailed. In this extremity he resorted for relief to the most abject and degrading superstitions; he shut himself up in a vault for fourteen days and nights, fasting and enduring the severest penances; and, under the influence of this gloomy fanaticism, he lost his reason, and fell into the most furious paroxysms of madness. In this melancholy situation his mother, out of compassion to him, directed him to be smothered. But this event did not take place till, under his fatal orders, thirty-nine princes of the Suffavean blood had suffered an untimely death. He was succeeded by Ashruff, the son of Meer Abdallah, and nephew of Meer Vais. The first period of Ashruff's reign was successful. He gained repeated victories over the Turkish armies, who were compelled to retire; and he concluded the war by compelling the Turkish court to acknowledge his title to the throne. But he was now assailed from another quarter by more serious dangers. Tamasp, the son of Shah Hussein, and the representative of the Suffavean princes, was in Mazanderan, where he was joined by a distinguished chief, Nadir Kouli, a well-known warrior, who now declared his resolution to expel every Afghan from the soil of Persia. Tamasp, from the day of his father's abdication, had assumed royal state, and, now that he was supported by Nadir and the nobles of Khorassan and Mazanderan, he found himself in a condition to exercise the authority of a sovereign. Nadir being invested with the sole command, soon succeeded in reducing Mushed and Herat, and at length all Khorassan, under the authority of Tamasp. Ashruff now prepared for the defence of his sovereign authority; and having raised an army, he advanced into Khorassan against his enemy, whose followers, he knew, were daily increasing. The Afghans
A. D. 1729. were defeated in a series of sanguinary actions, and pursued, first to Teheran, and finally to the gates of Ispahan. It was at first proclaimed in the city that the Afghans had obtained the victory; but the loud wailings of the women from the citadel soon disclosed the result of the battle. The night was passed in preparations for flight. The old men, women, and children, were mounted on mules and camels, and having packed up all the treasure and spoil which they could carry away, they took the route to Shiraz by break of day; the tyrant Ashruff having in the mean time cruelly murdered Shah Hussein, who was still detained a prisoner, and the pressure of circumstances only preventing a general massacre, which was fully intended. Nadir lost no time in pursuing the discouraged and flying Afghans. They were overtaken at Persepolis, and immediately fled towards Shiraz, where, though they were still 20,000 strong, they were deserted by their leader, who fled homewards with only two hundred followers. The army was dispersed in wandering bands, which were closely pursued and cut down by their exasperated foes; and Ashruff himself, whilst wandering in Seistan, was recognised and slain by Abdallah Khan, a soldier of Beloochistan, who sent his head, with a large diamond which he found on his person, to Shah Tamasp. The Afghan invasion was one of the most cruel calamities which ever befell the Persians. Within the short period of seven years they had massacred nearly a million of the inhabitants, laid waste the finest provinces of the country, and levelled the proudest edifices with the dust; yet they had neither the power nor the policy to maintain their conquest. From the first to the last day of their rule they appeared only a small body of foreigners in the midst of a great nation; and they accordingly fell before the first aspiring adventurer who could combine and direct the national resources against the ill-constructed fabric of their power. Persi

Nadir Shah was born in the province of Khorassan, on the 11th of November 1688. His father was in a low condition, earning a livelihood by making coats and caps of sheep-skins. He was taken prisoner by the Uzbecks at the age of seventeen, but made his escape from them after a captivity of four years. He was for a considerable period the chief of a band of robbers, the high way in those countries to distinction and power. He experienced many vicissitudes of fortune; and being a plunderer of known valour and resolution, he had collected 3000 followers, by whose aid he laid under contribution the extensive province of Khorassan. His friendship was now courted by A. D. 1
his uncle, who was in possession of the fort of Kelat. Nadir pretended to listen to his overtures; but deeming him an obstacle to his further rise, he treacherously slew him with his own hands, and proceeded to employ the power which he had thus acquired against the Afghans, the enemies of his country. And so well did he succeed in this popular and patriotic enterprise, that the Afghans were entirely expelled from the country; whilst, for his eminent services, he received a gift from his sovereign, Tamasp, of the four provinces of Khorassan, Mazanderan, Seistan, and Kerman. He then proceeded to attack the Turks, who still occupied the western provinces of Irak and Azerbijan, and having defeated them in various actions, took possession of Tabriz, Ardebil, and all the principal cities. He returned to quell an alarming insurrection of the Afghans, who were unable to withstand his victorious armies; and in the mean time the imbecile Tamasp commenced a war with the Turks, which ended in a disgraceful peace. He had for some time been a mere pageant in the hands of Nadir; and this unfortunate war, with other complaints against him, furnished a plausible pretence for his dethronement, which took place on the 16th of August 1732. He retired to Khorassan, where he was afterwards put to death by Reza Kouli, the son of Nadir, and with the knowledge, if not by the secret orders, of the father. His son, an infant eight months old, was seated on the throne; but Nadir was now in substance, as he was soon to be in form, the real sovereign. In 1736 the death of this infant removed the only obstacle to his ambition; and, in a vast assembly of his nobles and troops, he was, after much pretended reluctance, prevailed on to accept of the crown. This high dignity served only to give a fresh stimulus to his active and enterprising habits. In the course of a new war with the Turks, having regained the provinces which had been wrested from the imbecile Tamasp, and concluded a peace, he turned his arms eastward. Candahar and Balkh were besieged and taken by his son Reza Kouli, who passed the Oxus, and defeated the ruler of Bukharia and the Uzbecks. Afghanistan was afterwards subdued; and Nadir finally completed his military glory by the conquest of Delhi. A single battle was sufficient to disperse the Mogul host; and Nadir, with his triumphant legions, entered the capital, which made no resistance. Its treasures were plundered; and its inhabitants, who rose on the Persian soldiery, were, in revenge, given over to an indiscriminate massacre, in which neither age nor sex was spared. Nadir returned in triumph, loaded A. D. 1
with the spoils of one of the richest capitals of the East. He continued to prosecute his conquests on every side, and restored the ancient glory of the Persian empire, when it extended from the chain of the Caucasus eastward to the Indus.

But the glory of foreign conquest was tarnished by domestic tyranny. In an expedition against the Lesghees, a mountain tribe upon the western frontier, Nadir was wounded by an assassin, who fired on him from a wood. His suspicion fell on his son Reza Kouli, or had been instilled into his mind by artful intriguers. Under this impression he commanded his son into his presence, and immediately caused him to be deprived of his eyesight. But so struck was he with remorse after the deed had been done, that he vented his fury upon all around him; and fifty noblemen were put to death by his orders, because they had not come forward to sacrifice their lives for the young prince, the hope of his country. "It is not my eyes," says the prince, "that you have put out, but those of Persia." The mind of Nadir was deeply affected; he became gloomy and ferocious; all his future actions were deeds of horror; and he exceeded in barbarity all that has ever been recorded of the most bloody tyrants. The country languished under his extortions; and when he at last raised the people to insurrection, his fury knew no bounds, and he not only murdered individuals, but gave up whole cities to the destroying sword. Several of the principal officers of his court, learning that their names were in a proscribed list, resolved to anticipate the vengeance of the tyrant. The execution of the plot was committed to four chiefs who were employed about the palace, and who, on the pretext of business, rushed past the guards in the inner tents, and found the tyrant asleep. He was awakened by the noise, and had slain two of the conspirators, when he was deprived of life by a blow from Salah Beg, the captain of the guards.

The sudden death of Nadir Shah involved the country in the greatest distraction. He was succeeded by his nephew Ali, who took the name of Adil Shah. But his reign was short and inglorious. He was taken prisoner by his brother Ibrahim Khan, and put to death at Mushed, as his captor himself also was, being slain by the officer who guarded him. Shah Rokh, the grandson of Nadir, succeeded; but the throne was ere long usurped by Meerza Syud Mahommed, by whom Shah Rokh was taken prisoner and deprived of sight. The usurper being defeated and taken prisoner by Yusuf Ali, the principal general of Shah Rokh's army, was immediately put to death. The blind Shah Rokh was again raised to the throne; but the measures of his general, Yusuf Ali, were opposed by two chiefs, the respective heads of a Kurdish and an Arabian tribe, and by their joint efforts the faithful general of Shah Rokh was defeated and slain, and he himself again sent from a throne to a prison. The two chiefs, however, soon quarrelled; and Meer Aulum, the Arabian, triumphed, but only to fall before the rising power of the Afghans under Ahmed Khan Abdallee. This leader might at the time have easily accomplished the reduction of Persia. But judging more wisely, he assembled the principal chiefs, and proposed to them that the province which gave birth to Nadir should be given as a principality to his grandson. To this all the chiefs agreed, and Shah Rokh was again established in the undisturbed possession of Khorassan. At this period Persia was in a complete state of distraction, from the contentions of rival chiefs. Mahommed Hussein Khan, chief of the tribe of Kujurs, had established himself at Astrabad, and had brought under his authority the whole province of Mazanderan. The province of Azerbijan was under the rule of Azad Khan, an Afghan leader, who had been one of the generals of Nadir Shah. Gheelan was independent, under one of its own chiefs, Hidayet Khan. At this time Ali Murdan Khan, a chief of the tribe Bukteearee, took possession of Ispahan, and, resolving to elevate a prince of the house of Suffee to the throne, he invited the nobles to join his standard. The principal of those chiefs was Kurreen Khan, of the tribe of Zund, a man distinguished by his sagacity and courage, and between whom and Ali Murdan Khan a rivalship for power soon took place. Kurreen Khan, dreading the enmity of Ali Murdan, took the field against him. But his assassination soon afterwards left Kurreen undisputed master of the south of Persia. He was joined by most of the tribes from that country, and being at war with Azad Khan, he was entirely defeated by him in a general action, and so discouraged by the unpromising state of his affairs, that he meditated a retreat into India. But he was dissuaded from so unworthy a course by the remonstrances of his general Roostum Sultan, the chief of Khisht, who attacked the enemy in a narrow pass, and obtaining a complete victory, re-established the power of Kurreen Khan, who again occupied the city of Shiraz, where he employed his utmost efforts to recruit his army. Azad Khan, throwing himself on the clemency of his conqueror, was received into his service, and became one of his most attached followers. The most powerful enemy of Kurreen Khan was Mahommed Hussein Khan, the chief of the Kujurs, who ruled in Mazanderan. He advanced against Shiraz with a powerful force; but the city being bravely defended, he was compelled to raise the siege, and to retreat to Ispahan. He afterwards engaged Kurreen in a general action, in which, being deserted by part of his troops, he was defeated and slain. The whole province of Mazanderan then submitted to the conqueror, and this was followed by the submission of Gheelan and the greater part of Azerbijan. Khorassan was the only province which he did not subdue; and his forbearance is ascribed to compassion for the blind Shah Rokh, who still retained this remnant of his extensive dominions.

Kurreen Khan was distinguished by a love of justice and a moderation not usual amongst eastern princes. He died in the year 1779, in the eightieth year of his age, after a reign of twenty-six years. His administration was generally just and beneficent. He encouraged agriculture and commerce, which greatly revived during the latter years of his reign; and he protected, by his justice, Christians as well as Mahommedans. He never refused mercy to a fallen foe, though he sometimes punished severely, that he might strike terror into his enemies. Many stories are recorded of him, which display the kindness of his heart. He often repeated an anecdote of his early life. "When I was a poor soldier," said Kurreen, "in Nadir Shah's camp, my necessity led me to steal from a saddler a gold-embossed saddle, which had been sent by an Afghan chief to be repaired. I soon afterwards learned, that the man from whose shop it had been taken was lying in prison under sentence of death. My conscience smote me, and I replaced the saddle exactly on the place whence I took it. I watched till it was discovered by the saddler's wife, who on seeing it gave a scream of joy, fell down upon her knees, and prayed aloud that the person who had brought it back might live to have a hundred gold-embossed saddles. I am quite certain," he added, smiling, "that the honest prayer of the old woman has aided my fortune in the attainment of that splendour which she desired I should enjoy."[1] The humane disposition of this prince prompted him to acts of mercy; and the generous confidence with which he treated those whom he forgave, never failed to attach them to his person. It is the practice of the Persian kings to devote a portion of their time to hear the complaints of their subjects; and the following anecdote related of Kurreen Khan illustrates the temper and consideration with which he performed this important duty.

---

[1] Sir John Malcolm's History of Persia, chap. xviii.

He was one day on the point of retiring from the judgment-seat, harassed and fatigued with a long attendance, when a suitor rushed forward in the greatest distraction, and, calling aloud for justice, complained that he had been robbed and plundered by thieves of all he possessed. “What was you about,” said the prince, “when you was robbed?” “I was asleep,” answered the man. “And why did you sleep?” exclaimed Kurreen, in an impatient tone. “Because,” said the suitor, “I made a mistake, and thought you was awake.” The royal judge, pleased with this manly boldness, turned to his vizier, and desired him to pay the merchant's losses from the treasury. “We must,” he added, “try to recover the property from the robbers.”

After the death of Kurreen Khan, the succession to the crown was, as usual, disputed, and in the course of these contests his four sons either perished under the daggers of assassins, or were sacrificed in the intrigues of ambitious chiefs contending for the crown. Zuckee Khan, the moment his father died, assumed the reins of government; whilst Saaduck Khan at the same time evacuated Bassorah, and advanced towards Shiraz. But he was unable to contend against Zuckee Khan, and was soon forced to retire. In the mean time, Aga Mahommed Khan Kujur, who had been detained prisoner at Shiraz, and who was duly apprized by his sister, an inmate of the royal harem, of the progress of Kurreen Khan's illness, and at last of his death, contrived to escape to Mazanderan, where he proclaimed himself a competitor for the throne. The cruelties of Zuckee, who had treacherously murdered a number of his rebellious nobles, after pledging his faith for their safety, soon provoked revenge, and he was himself put to death at Yezdikhanst. Aboul Futteh Khan was proclaimed king of Persia the moment Zuckee Khan was put to death. Saaduck Khan hastened from Kerman to Shiraz when he heard of the assassination of Zuckee Khan, and proclaimed himself king, arresting the person of Aboul Futteh Khan, and causing his eyes to be put out. He was besieged in his capital by his nephew Ali Mourad Khan, his most formidable enemy, and, being obliged to surrender, he was put to death, with most of his sons. Ali Mourad was, in his turn, put down by another rival; and Jaffier Khan, nephew of Kurreen, and Aga Mahommed, were at length the only rivals left to contend for the crown. The former having disgusted one of his chief supporters, Hajee Ali Kouli, he engaged in a conspiracy against him; and having put poison in his victuals, he and others rushed into his chamber when he was writhing under its effects, and put a period to his existence. He was succeeded by Lootf Ali Khan, who was one of the most remarkable characters recorded in the Persian annals. His appearance was greatly in his favour; his fine countenance, full of animated expression; his form tall and graceful, and, though slender, active and strong. He was at Kerman when he heard of his father's murder, which took place in the year 1789; and though Syud Mourad Khan was at first proclaimed king by the conspirators, yet, by the aid of Hajee Ibrahim, appointed by his father the first magistrate of the province of Fars, he was soon enabled to assert his claim to the crown. He was bold in counsel and fearless in action, and maintained a long and well-sustained struggle for the sovereignty, in the course of which he performed prodigies of valour. But he wanted prudence and temper, and had no control over his passions. Unbending in his pride, and harsh and unconciliating in his manners, he employed terror as the chief source of his influence. His great error was in quarrelling with and disgusting his faithful minister Hajee Ibrahim, a statesman of consummate prudence and talents, who abandoned his service for that of his rival and enemy, Aga Mahommed Khan, and was ever afterwards his most formidable enemy.[1] Lootf Ali maintained the contest for six years; the “slightest spark,” according to a Persian author, “always rekindling the flame of hope in the breast of the warrior.” But he was at length overwhelmed by the superior forces of his enemy; and, flying from Persia, he was treacherously seized, after a brave resistance, in which he was seriously wounded, and being delivered into the hands of Aga Mahommed Khan, was treated with a brutality of insult which is too shocking to be described, and which, Sir John Malcolm adds, disgraced human nature. His eyes were torn out, and he was sent to languish out a miserable existence in Teheran, where an order was soon afterwards sent for his execution. Lootf Ali terminated his extraordinary career in 1795, in the twenty-fifth year of his age. Nor was Aga Mahommed's cruel treatment of the inhabitants of Kerman less shocking. This place was the last stronghold of Lootf Ali. It was defended by him with his usual bravery, and being at length taken by treachery, became the scene of the most dreadful atrocities. The place was almost depopulated. Many women and children, to the number of 20,000, were carried into slavery. The men were murdered, and numbers were deprived of sight, many of whom were afterwards seen by Sir John Malcolm begging their bread. Lootf Ali was the last of the Zund family of princes, who had ruled over Persia for nearly half a century.

Aga Mahommed Khan having now firmly established himself upon the throne of Persia, his first care was to restore order throughout his dominions, and to repel foreign aggression. Having tranquillized the southern and central provinces, he invaded Armenia and Karabang, and marching straight to Teflis, he defeated Heraclius, prince of Georgia; and having taken the city, he sacked it, and made a dreadful slaughter of the inhabitants, carrying into slavery 20,000 women and children. He then turned his arms eastward, subdued Khorassan, and repressed the incursions of the pillaging Turcomans in the vicinity of Astrabad, as well as of the Uzbecks in Bukharia. But however rigorous his administration, and however active in the field, all his exploits were stained with cruelties. His avarice was unbounded; and he scrupled at no atrocity to gratify it. He had long thirsted after the jewels of which Nadir Shah had despoiled India, and these he wrested without remorse from their unfortunate possessors. From the aged and blind Shah Rokh he extorted, by the severest tortures, several of those which were the most precious, particularly a ruby, which had belonged to Aurungzebe, and which was of extraordinary size and value. This precious jewel was retained to the last, until boiling lead had been poured upon the head of the unhappy prince, when, in his intolerable agony, he declared where it was hidden. He was afterwards conveyed to Damghan in Khorassan, where he died in a few days, in the sixty-third year of his age, in consequence of the tortures to which he had been subjected.

Aga Mahommed Khan succeeded in tranquillizing the country, partly by policy, and still more by terror. He often spared his enemies, and conciliated them, not however from any feeling of humanity, but from a sense of his own interest; for his disposition was stern, cruel, and vindictive, and his reign presents a series of atrocities scarcely equalled in the bloody annals of the East. Sir John Malcolm palliates his atrocities, and observes, that though his executions are murders, we must not assume that justice is always violated, because the form of administering it is repugnant to our feelings; and, further, he adds, that "the punishment of bodies of men to deter others of similar condition from equal guilt, is perhaps the only mode by which uncivilized nations can be preserved in peace."[1] But according to Sir John Malcolm's own account, not only the forms, but every principle of justice, were violated by the executions, or murders, as he justly calls them, of the Persian despot. Ali Khan, a chief of the Affshar tribe, had opposed Aga Mahommed Khan in the field. He was decoyed into his power by the deepest treachery, and being arrested amidst fawning and caresses, his eyes were put out. The brave and generous Jaffier Kouli, his own brother, was in like manner seduced, by the kindest assurances, to visit the court at Teheran, where he was welcomed with every appearance of cordiality, and the night passed in peace. Next day Aga Mahommed observed, "You have not, I believe, looked at the new palace; walk there with Baba Khan (his son), and after you have seen it, return to me." But the moment he entered the portico, some assassins who had been stationed there fell upon him and slew him. This act, unequalled in atrocity, stamps upon Aga Mahommed the character of a cold-blooded villain, whose portrait may be truly drawn in the words of the immortal poet, "I can smile, and smile, and murder when I smile." And were not justice and humanity alike violated in the cruel torture of the blind Shah Rokh? The punishment of bodies of men, that is, the indiscriminate massacre of thousands, including infants and old men, and the carrying off of women by violence, Sir John Malcolm palliates on the tyrant's plea, necessity; as if cruelty, and not justice and humanity, were the only mode of maintaining peace amongst uncivilized nations, or as if it were quite allowable in political morality to kill one half of a nation in order to compel the other to abandon their barbarous mode of living. The truth is, that Aga Mahommed appears to have been a prodigy of cruelty, swayed alternately by avarice and revenge, and his own absolute will, the only warrant of his evil deeds; so that it is idle to try his conduct by any moral test. Many stories are related of his implacable cruelty and revenge. He not only murdered or deprived of sight all the relations of Lootf Ali, but he dug up the bones of the virtuous Kurreen Khan and those of Nadir Shah, which he caused to be burned at the entrance of his palace, that he might indulge in the savage pleasure of trampling on their remains. The following is a trait of his vindictive disposition. "I could not," he has been known to say, "express openly the hatred and revenge I harboured against the murderers of my father, and the despoilers of my inheritance; but whilst sitting with Kurreen Khan in his hall of audience, I often used to cut his fine carpets with a pen-knife concealed under my cloak, and felt some relief in doing him this secret injury. It was foolish, and betrayed a want of forecast; for these carpets are mine, and I might have even then calculated on their being so."

---

[1] See, in Sir John Malcolm's excellent History of Persia, a full account of all the transactions of Lootf Ali's reign. Sir John was personally acquainted with Hajee Ibrahim, who informed him that his principal reason for taking part with Mahommed Khan was, to save his country from the continual petty wars with which it had been long afflicted. (Vol. ii. chap. xix. p. 183.)

Aga Mahommed Khan being apprised of the invasion of Persia by Russia, sent his army to defend the frontier. But the death of the Empress Catharine relieved Persia from the serious danger with which it was threatened. Aga Mahommed then determined to move towards Georgia; and having received a friendly deputation from the inhabitants of Sheshah, he proceeded with some light troops, and took possession of this important fortress. Three days afterwards, a dispute having occurred between a Georgian slave, a personal attendant on the monarch, and another servant, respecting some money that was missing, the king, enraged at the noise which they made, directed that they should both be put to death. Saaduck Khan Shekakee, a nobleman of the highest rank, solicited their pardon, which was refused; but as it was the night of Friday, sacred to prayer, their lives were spared till next morning, and, with a singular infatuation, the despot permitted them to perform their usual services about his person. Despair gave them courage; and whilst the monarch was asleep, they entered his tent, accompanied by an associate, and stabbed with their poniards one of the ablest monarchs (according to Sir John Malcolm) who ever sat on the throne of Persia. He was then in the sixty-third year of his age, and had ruled for upwards of twenty years, though he had enjoyed the undisputed sovereignty of the country for only a small portion of that time.

Aga Mahommed Khan was in person so slender, that he appeared like a youth of fourteen or fifteen. His face was beardless and shrivelled, resembling that of an aged and wrinkled woman; it was at no time pleasant or agreeable, and when clouded with indignation, as it often was, its expression was horrible. He was so sensible of this, that he could not bear any one to look at him. "The first passion of his mind," says Sir John Malcolm, "was the love of power, the second avarice, and the third revenge. In all these he indulged to excess. He was harsh and abrupt, and often cruel to his ministers and to his domestics, who trembled at the sound of his shrill and dissonant voice, which was generally raised to utter some term of gross abuse, or issue an order for punishment. The minister Hajee Ibrahim was, however, an exception. He was uniformly treated with unbounded confidence." "The penetration of the monarch," says the historian of Persia so often quoted, "discovered at once the talents of that extraordinary man, whose plainness of manner, blunt speech, manly fortitude, and astonishing knowledge of public affairs, led Aga Mahommed to give him his entire confidence, and no confidence was ever better rewarded. The minister, though he contrived to gratify the avarice of his master, and to promote his ambition, often obtained favour for others through the kindness of his disposition, whenever he could interfere without danger to himself. He was generally dressed in the plainest manner, and he greatly disliked the hyperbolical complimentary style of the East, insomuch that, when the secretaries of the court, in reading papers to him, commenced their flowery introductions, he desired them to 'pass over the nonsense, and proceed to the subject of the letter at once.'"

By the influence and wise management of Hajee Ibrahim, the crown was secured to the nephew of the deceased monarch, who assumed the sovereignty under the title of Futteh Ali Khan. Saaduck Khan made a feeble effort to oppose him, but was attacked and defeated. Two other attempts to usurp the crown, the one made by the king's brother Hussein Kooli Khan, and the other by Mahommed Khan, a prince of the Zund family, were subdued; and since this period the internal tranquillity of the country has not been disturbed. The most important events in the reign of Futteh Ali were connected with the wars which he entered into with Russia, and which generally proved unfavourable to Persia. In 1800 Georgia finally submitted to the dominion of Russia; and in 1803 Mingrelia was subdued. Gonjah was taken; and although the invaders were forced to raise the siege of Erivan, they overran Daghistan and Shirwan, and, in 1805, Karabang yielded to their victorious arms. The interference of Great Britain arrested the progress of Russian conquest; and Persia was saved from further inroads by the treaty of Goolistan, concluded in October 1813, which fixed the relative boundaries so indefinitely, as, after much tedious negotiation, to give rise to a new war. In this war, which commenced in the month of July 1826, the prince royal of Persia took the field, with forty thousand men, twelve thousand of whom were regulars; and at the outset he gained several important advantages. But the superior discipline of the Russian armies, trained in the wars of Europe, triumphed in the end; and in 1828, seeing no prospect of maintaining the war with success, peace was again sought for through the mediation of Great Britain. It was concluded on the 21st of February, at Turkomanshee. Besides large cessions of territory, namely, the Khanat of Erivan and that of Nakshivan, and the greater part of Talish, including all the islands which fall within its direction, Persia agreed to pay ten crores, of 500,000 each, of tomauns, as an indemnification for the expenses of the war. Since this treaty, the peace of the two countries has not been disturbed; and the prince royal, turning his attention to the internal concerns of his kingdom, has succeeded in reducing the rebellious chiefs of Khorassan. By the aid of a Polish refugee, equally skilful and brave, he acquired possession of Yeza, took Toorshish and Khabooshan by storm, and reduced to obedience all the other chiefs in that quarter.

---

[1] History of Persia, vol. ii. p. 272.

Still it is manifest, from the accounts of all travellers, that the present dynasty of the Kujurs stands upon a precarious foundation. The misrule which pervades every district of the country, the tyranny and extortions which oppress all classes, and the insecurity of life and property, have excited throughout the kingdom a thorough detestation of the present rulers. The people sigh for that security, that religious liberty, and that protection, which they know to be enjoyed under the British government in India; and it is well known that petitions have been addressed to influential quarters from a great proportion of the chiefs and nobles, and from other classes, craving permission to throw themselves on the protection of Britain, and declaring that if they are disappointed, they will solicit the aid of Russia. Any government, even that of foreigners, which would give them security for their lives and properties, they consider as preferable to the hated yoke of the Kujur tyrant. (F.)

PERSICUS Sinus, in *Ancient Geography*, a part of the sea which the Romans called *Mare Rubrum*, and the Greeks *Mare Erythræum*. On the east it is bounded by Arabia Felix, between which and Caramania it runs into the land, and washes Persia on the south.

PERSIUS Flaccus (Aulus), a celebrated Roman satirist, was a native of Volaterra in Etruria, and descended of an equestrian family of considerable eminence in the state. The little that we know respecting his personal history is chiefly derived from a slight sketch commonly ascribed to the pen of Suetonius. He was born A. D. 34, in the twentieth year of the reign of Tiberius, and died A. D. 62, in the twenty-eighth year of his age, and in the eighth of the reign of Nero. He lost his father at an early age; and his mother, Fulvia Sisennia, removed to Rome, that her son might enjoy the best education which the imperial city could furnish. He studied first under the grammarian Rhemmius Palæmon, and the rhetorician Virginius Flavus; and when he reached his sixteenth year, he was placed under the Stoic philosopher Annæus Cornutus, to whom he became passionately attached, and from whom he imbibed those tenets by which his writings are characterized. In his younger days he was much in the company of Pætus Thrasea, whose noble character must no doubt have tended to form the mind of Persius to virtuous habits. He was also intimately acquainted with Lucan, who had been his fellow-pupil under Cornutus. His admiration of the Satires of Lucilius is said to have first turned his attention to the study of poetry. His character was austere, his mode of life pure and blameless, and his affection for his friends strong and unbending. He left a considerable property to his mother and sisters; and his books, which are said to have consisted of seven hundred volumes, he bequeathed to his friend Cornutus. The philosopher recommended to his mother that she should commit to the flames all his manuscripts except his Satires. These were accordingly preserved, and consist of one book, divided, according to some, into five satires, and according to others, into six.

If we consider the nature and general scope of the writings of Persius, we shall find the severe tenets of the Stoics everywhere pervading them, and that the poet, unable to conceal the virtuous indignation which naturally rises in his breast, in contemplating the ignoble and vicious lives of those by whom he was surrounded, pours forth in strong and unmeasured language the feelings which occupy his soul. He disdains, like Horace, to laugh at those vices which he regards with such deep-felt abhorrence. He has none of the lively and playful humour of Horace; and there is a sternness and an austerity in his remarks, which leave a painful impression on the mind. He shows that he is entirely occupied with his subject, and that his sentiments flow from a mind deeply convinced of their truth. His language, however, is at times so obscure and enigmatical, that it is difficult to attach a meaning to it, even with the assistance of the ancient scholia. This circumstance has tended to detract much from the merits of Persius; but Quintilian and Martial, amongst the ancients, have both expressed a high admiration of his talents and writings.

The best edition of his Satires is that of Ruperti, published along with the Satires of Juvenal, Leipzig, 1819. The best separate edition is that of Franz Passow, with a metrical translation and introduction to the life and writings of Persius, Leipzig, 1809.

PERSON, an individual of a rational and intelligent nature. Thus we say, an ambassador represents the person of his prince; and that, in law, the father and son are reputed the same person.

Person, in *Grammar*, a term applied to such nouns or pronouns as, being either prefixed or understood, are the nominatives in all inflections of a verb. See Grammar.

PERSONAL, any thing that concerns, or is restricted to, the person.

Personal Action, in *Law*, is an action levied directly and solely against the person, in opposition to a real or a mixed action.

Personal Verb, in *Grammar*, a verb conjugated in all the three persons, and so called in opposition to an impersonal verb, or that which has the third person only.

PERSONALITY, in the schools, is that which constitutes an individual a distinct person.

PERSONIFYING, the assigning to an inanimate object the sentiments and language of a living being.

PERSPECTIVE.

Perspective is the art of drawing upon a plane surface true resemblances or pictures of objects, as the objects themselves appear to the eye from any distance and situation, real or imaginary.

It was in the sixteenth century that perspective was revived, or rather re-invented. It owes its birth to painting, and particularly to that branch of it which was employed in the decorations of the theatre, where landscapes were properly introduced, and which would have looked unnatural and horrid if the size of the objects had not been pretty nearly proportioned to their distance from the eye. We learn from Vitruvius, that Agatharchus, instructed by Æschylus, was the first who wrote upon this subject; and that afterwards the principles of the art were more distinctly taught by Democritus and Anaxagoras, the disciples of Agatharchus. Of the theory of this art, as described by them, we know nothing, since none of their writings have escaped the general wreck that was made of ancient literature in the dark ages of Europe. However, the revival of painting in Italy was accompanied with a revival of this art.

The first person who attempted to lay down the rules of perspective was Pietro del Borgo, an Italian. He supposed objects to be placed beyond a transparent tablet, and endeavoured to trace the images which rays of light emitted from them would make upon it. But we do not know what success he had in this attempt, because the book which he wrote upon the subject is not now extant. It was, however, very much commended by the famous Egnazio Dante; and, upon the principles of Borgo, Albert Durer constructed a machine, by which he could trace the perspective appearance of objects.

Balthazar Perussi studied the writings of Borgo, and endeavoured to render them more intelligible. To him we owe the discovery of points of distance, to which all lines that make an angle of forty-five degrees with the ground line are drawn. A little time after, Guido Ubaldi, another Italian, found that all the lines that are parallel to one another, if they be inclined to the ground line, converge to some point in the horizontal line; and that through this point also, a line drawn from the eye, parallel to them, will pass. These principles, put together, enabled him to make out a pretty complete theory of perspective.

Great improvements were made in the rules of perspective by subsequent geometricians; particularly by Professor Gravesande, and still more by Dr Brooke Taylor, whose principles are in a great measure new, and far more general than any that had been made before his time.

In order to understand the principles of perspective, it will be proper to consider the plane on which the representation is to be made as transparent, and interposed between the eye of the spectator and the object to be represented. Thus, suppose a person at a window looks through an upright pane of glass at any object beyond it, and, keeping his head steady, draws the figure of the object upon the glass with a black-lead pencil, as if the point of the pencil touched the object itself; he would then have a true representation of the object in perspective, as it appears to his eye.

In order to this, two things are necessary; first, that the glass be laid over with strong gum-water, which, when dry, will be fit for drawing upon, and will retain the traces of the pencil; and, secondly, that he look through a small hole in a thin plate of metal, fixed about a foot from the glass, between it and his eye, and that he keep his eye close to the hole, otherwise he might shift the position of his head, and consequently make a false delineation of the object.

Having traced the figure or outline of the object, he may go over it again with pen and ink, and when the ink is dry, put a sheet of paper upon it, and trace it thereon with a pencil; then taking away the paper and laying it upon a table, he may finish the picture by giving it the colours, lights, and shades, as he sees them in the object itself. By these means he will have a true resemblance of the object.

To every person who has a general knowledge of the principles of optics, this must be self-evident. For, as vision is occasioned by pencils of rays coming in straight lines to the eye from every point of the visible object, it is plain that, by joining the points in the transparent plane, through which all those pencils respectively pass, an exact representation must be formed of the object, as it appears to the eye in that particular position, and at that determined distance; and were pictures of things to be always first drawn on transparent planes, this simple operation, with the principle upon which it is founded, would comprehend the whole theory and practice of perspective. As this, however, is far from being the case, rules must be deduced from the sciences of optics and geometry, for drawing representations of visible objects upon opaque planes; and the application of these rules constitutes what is properly called the *art of perspective.*

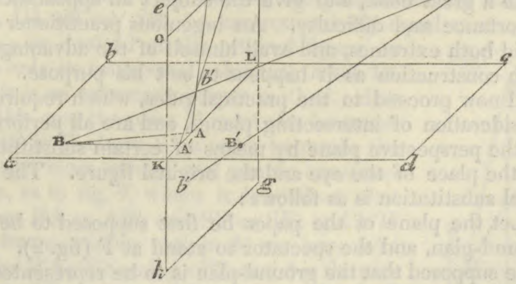
Previously to our laying down the fundamental principles of this art, it may not be improper to observe, that when a person stands right against the middle of one end of a long avenue or walk, which is straight and equally broad throughout, the sides thereof appear to approach nearer and nearer to each other as they are further and further from his eye; or the angles under which their different parts are seen become less and less according as the distance from his eye increases; and if the avenue be very long, the sides of it at the farthest end will seem to meet, and there an object that would cover the whole breadth of the avenue, and be of a height equal to that breadth, would appear to be only a mere point.

Having made these preliminary observations, we shall now proceed to the practice of perspective, which is built upon the following

THEOREM I.

Let *abcd* (fig. 1) represent the ground plan of the figure to be thrown into perspective, and *efgh* the transparent plane through which it is viewed by the eye at E. Let these planes intersect in the straight line KL. Let B be any

Fig. 1.



point in the ground-plan, and BE a straight line, the path of a ray of light from that point to the eye. This will pass through the plane *efgh* in some point *b*; or B will be seen through that point, and *b* will be the picture, image, or representation of B.

If BA be drawn in the ground-plan, making any angle BAK with the common intersection, and EV be drawn parallel to it, meeting the picture-plane or perspective plane in V, and VA be drawn, the point *b* is in the line VA so situated that BA is to EV as *b*A to *b*V.

For since EV and BA are parallel, the figure BA*b*VE*b*B is in one plane, cutting the perspective plane in the straight line VA; the triangles BA*b*, EV*b*, are similar, and BA : EV = *b*A : *b*V.

Cor. 1. If B be beyond the picture, its picture *b* is above the intersection KL; but if B be between the eye and the picture, as at B′, its picture *b*′ is below KL.

2. If two other parallel lines BA′, ES, be drawn, and A′, S, be joined, the picture of B is in the intersection of the lines AV and A′S.

3. The line BA is represented by *b*A, or *b*A is the picture of BA; and if AB be infinitely extended, it will be represented by AV. V is therefore called the *vanishing point* of the line AB.

4. All lines parallel to AB are represented by lines converging to V from the points where these lines intersect the perspective-plane; and therefore V is the vanishing point of all such parallel lines.

5. The pictures of all lines parallel to the perspective-plane are parallel to the lines themselves (fig. 8).

6. If through V (fig. 1) be drawn HVO parallel to KL, the angle EVH is equal to BAK.

Remark. The proposition now demonstrated is not limited to any inclination of the picture-plane to the ground-plane; but it is usual to consider them as perpendicular to each other, and the ground-plane as horizontal. Hence the line KL is called the *ground-line*, and OH the *horizon-line*; and OK, perpendicular to both, is called the *height of the eye.*

If ES be drawn perpendicular to the picture-plane, it will cut it in a point S of the horizon-line directly opposite to the eye. This is called the *point of sight*, or *principal point.*

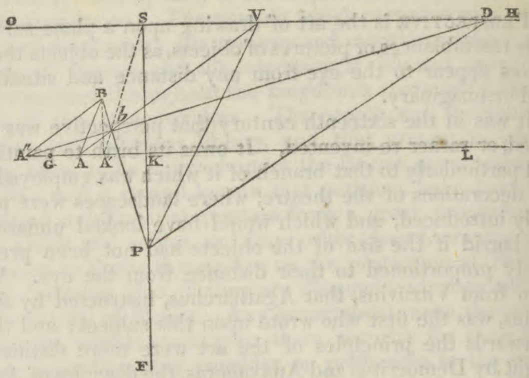
7. The pictures of all vertical lines are vertical, and the pictures of horizontal lines are horizontal, because these lines are parallel to the perspective plane.

8. The point of sight S is the vanishing point of all lines perpendicular to the perspective plane.

The above proposition is a sufficient foundation for the whole practice of perspective, whether on direct or inclined pictures, and serves to suggest all the various practical constructions, each of which has advantages which suit particular purposes. Writers on the subject have either confined themselves to one construction, from an affectation of simplicity or fondness for system; or have multiplied precepts, by giving every construction for every example, in order to make a great book, and give the subject an appearance of importance and difficulty. An ingenious practitioner will avoid both extremes, and avail himself of the advantage of each construction as it happens to suit his purpose. We shall now proceed to the practical rules, which require no consideration of intersecting planes, and are all performed on the perspective plane by means of certain substitutions for the place of the eye and the original figure. The general substitution is as follows:

Let the plane of the paper be first supposed to be the ground-plan, and the spectator to stand at F (fig. 2). Let it be supposed that the ground-plan is to be represented on a plane surface, standing perpendicularly on the line GKL of the plan, and that the point K is immediately opposite to the spectator, or that FK is perpendicular to GL: then FK is equal to the distance of the spectator's eye from the picture.

Fig 2.



Now suppose a piece of paper laid on the plan with its straight edge lying on the line GL; draw on this paper KS perpendicular to GL, and make it equal to the height of the eye above the ground-plan. This may be much greater than the height of a man, because the spectator may be standing on a place much raised above the ground-plan. Observe also that KS must be measured on the same scale on which the ground-plan and the distance FK were measured. Then draw HSO parallel to GL. This will be a horizontal line, and (when the picture is set upright on GL) will be on a level with the spectator's eye, and the point S will be directly opposite to his eye. It is therefore called the *principal point*, or *point of sight.* The distance of his eye from this point will be equal to FK. Therefore make SP (in the line SK) equal to FK, and P is the projecting point or substitute for the place of the eye. It is sometimes convenient to place P above S, sometimes to one side of it on the horizontal line, and in various other situations; and writers ignorant of, or inattentive to, the principles of the theory, have given it different denominations, such as *point of distance, point of view,* &c. It is merely a substitute for the point F in fig. 1, and its most natural situation is below, as in this figure.

The art of perspective is conveniently divided into Ichnography, which teaches how to make a perspective draught of figures on a plane, commonly called the ground-plan; and Scenography, which teaches how to draw solid figures, or such figures as are raised above this plan.

Prob. 1. *To put into perspective any given point of the ground-plan.*

First general construction.

From B and P (fig. 2) draw any two parallel lines BA, PV, cutting the ground-line and horizon-line in A and V, and draw BP, AV, cutting each other in *b*; *b* is the picture of B.

For it is evident that BA, PV of this figure are analogous to BA and EV of fig. 1, and that BA : PV = *b*A : *b*V.

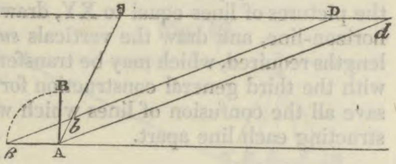
If BA′ be drawn perpendicular to GL, PV will fall on PS, and need not be drawn. A′V will be A′S. This is the most easy construction, and nearly the same with Ferguson's.

Second general construction.

Draw two lines BA, BA″, and two lines PV, PD, parallel to them, and draw AV, A″D, cutting each other in *b*; *b* is the picture of B by Cor. 2. This construction is the foundation of all the rules of perspective that are to be found in the books on this subject. They appear in a variety of forms, owing to the ignorance or inattention of the authors to the principles. The rule most generally adhered to is as follows;

Draw BA perpendicular to the ground-line, and AS to the point of sight, and set off $A\beta$ equal to BA. Set off SD equal to the distance of the eye in the opposite direction from S that β is from A, where B and E of fig. 1 are on opposite sides of the picture; otherwise set them the same way. D is called the point of distance. Draw βD, cutting AS in b. This is evidently equivalent to drawing BA′ and PS perpendicular to the ground-line and horizon-line, and BA″ and PD (fig. 2) making an angle of 45° with these lines, with the additional puzzle about the way of setting off A′A″ and SD, which is avoided in the construction here given.

Fig. 3.



This usual construction, however, by a perpendicular and the point of distance, is extremely simple and convenient; and two points of distance, one on each side of S, serve for all points of the ground-plan. But the first general construction requires still fewer lines, if BA be drawn perpendicular to GL, because PV will then coincide with PS.

Third general construction.

Draw BA (fig. 3) from the given point B perpendicular to the ground-line, and AS to the point of sight. From the point of distance D set off Dd equal to BA, on the same or the contrary sides as S, according as B is on the same or the contrary side of the picture as the eye. Join d A, and draw Db parallel to dA. b is the picture of B. For SD, Dd are equal to the distances of the eye and given point from the picture, and SD : Dd = b S : bA.

This construction does not naturally arise from the original lines, but is a geometrical consequence from their position and magnitude; and it is of all others the most generally convenient, as the perpendicular distances of any number of points may be arranged along SD without confusion, and their direct situations transferred to the ground-line by perpendiculars such as BA; and nothing is easier than drawing parallels, either by a parallel ruler or a bevel square, used by all who practise drawing.

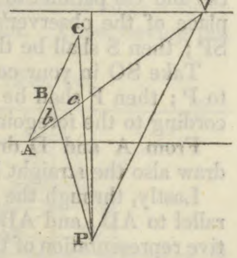
Prob. 2. *To put any straight line* BC *of the ground-plan in perspective.*

Find the pictures b, c, of its extreme points by any of the foregoing constructions, and join them by the straight line bc.

Perhaps the following construction will be found very generally convenient.

Produce CB till it meet the ground-line in A, and draw PV parallel to it; join AV, and draw PB, PC, cutting AV in b, c. V is its vanishing point, by Cor. 3 of the fundamental theorem.

Fig. 4.



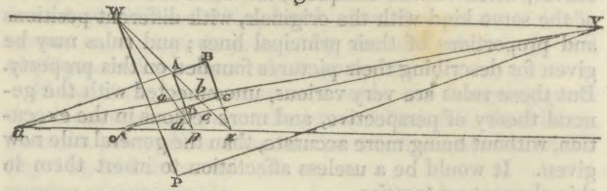
It must be left to the experience and sagacity of the drawer to select such circumstances as are most suitable to the multiplicity of the figures to be drawn.

Prob. 3. *To put any rectilineal figure of the ground-plan in perspective.*

Put the bounding lines in perspective, and the problem is solved.

The variety of constructions of this problem is very great, and it would fill a volume to give them all. The most generally convenient is to find the vanishing points of the bounding lines, and connect these with the points of their intersection with the ground line. For example, to put the square ABCD (fig. 5) into perspective.

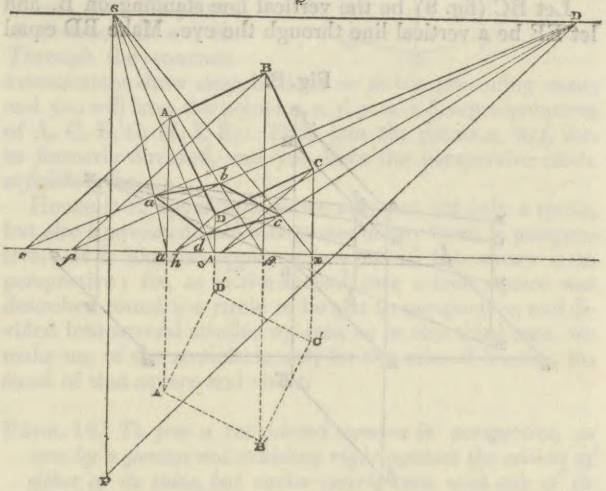
Fig. 5.



Draw from the projecting point PV, PW, parallel to AB, BC, and let AB, BC, CD, DA, meet the ground line in α, κ, δ, β, and draw αV, δV, κW, βW, cutting each other in $abcd$, the picture of the square ABCD. The demonstration is evident.

This construction, however, runs the figure to great distances on each side of the middle line, when any of the lines of the original figure are nearly parallel to the ground-line. The following construction avoids this inconvenience.

Fig. 6.

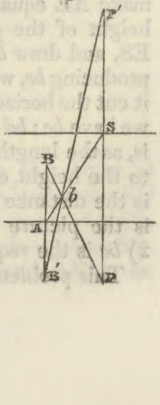


Let D be the point of distance. Draw the perpendiculars Aα, Bβ, Cκ, Dδ, and the lines Ae, Bf, Cg, Dh, parallel to PD. Draw Sα, Sβ, Sκ, Sδ, and De, Df, Dg, Dh, cutting the former in a, b, c, d, the angles of the picture.

It is not necessary that D be the point of distance; only the lines Ae, Bf, &c. must be parallel to PD.

Remark. In all the foregoing constructions the necessary lines (and even the finished picture) are frequently confounded with the original figure. To avoid this great inconvenience, the writers on perspective direct us to transpose the figure; that is, to transfer it to the other side of the ground-line, by producing the perpendiculars Aα, Bβ, Cκ, Dδ, till αA′ βB′, &c. are respectively equal to Aα, Bβ, &c.; or, instead of the original figure, to use only its transposed substitute A′B′C′D′. This is an extremely proper method. But in this case the point P must also be transposed to P′ above S, in order to retain the first or most natural and simple construction, as in fig. 7, where it is evident, that when BA = AB′, and SP = SP′, and B′P′ is drawn, cutting AS in b, we have bA : bS = B′A : P′S = BA : PS, and b is the picture of B; whence follows the truth of all the subsequent constructions with the transposed figure.

Fig. 7.



Prob. 4. *To put any curvilineal figure on the ground-plan into perspective.*

Put a sufficient number of its points in perspective by the foregoing rules, and draw a curve line through them.

It is well known that the conic sections and some other curves, when viewed obliquely, are conic sections or curves of the same kind with the originals, with different positions and proportions of their principal lines; and rules may be given for describing their pictures founded on this property. But these rules are very various, unconnected with the general theory of perspective, and more tedious in the execution, without being more accurate, than the general rule now given. It would be a useless affectation to insert them in this elementary treatise.

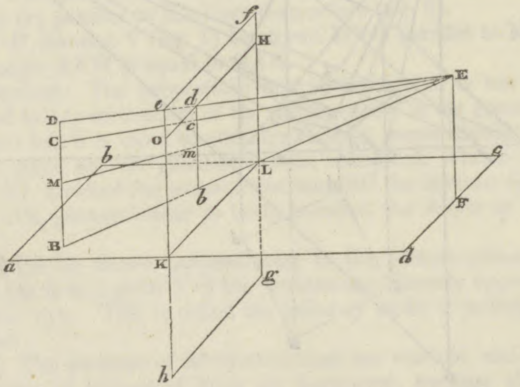
We come, in the next place, to the delineation of figures not in a horizontal plane, and of solid figures. For this purpose it is necessary to demonstrate the following

THEOREM II.

The length of any vertical line standing on the ground plane is to that of its picture as the height of the eye to the distance of the horizon-line from the picture of its foot.

Let BC (fig. 8) be the vertical line standing on B, and let EF be a vertical line through the eye. Make BD equal to EF, and draw DE, CE, BE. It is evident that DE will cut the horizon-line in some point *d*, CE will cut the picture-plane in *c*, and BE will cut it in *b*, and that *bc* will be the picture of BC, and is vertical, and that BC is to *bc* as BD to *bd*, or as EF to *bd*.

Fig. 8.

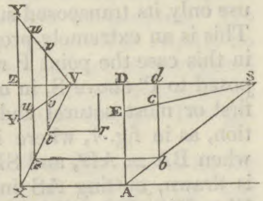


Cor. The picture of a vertical line is divided in the same ratio as the line itself. For BC : BM = *bc* : *bm*.

Prob. 5. *To put a vertical line of a given length in perspective standing on a given point of the picture.*

Through the given point *b* (fig. 9) of the picture draw S*b*A from the point of sight, and draw the vertical line AD, and make AE equal to the length or height of the given line. Join ES, and draw *bc* parallel to AD, producing *bc*, when necessary, till it cut the horizontal line in *d*, and we have *bc* : *bd* = AE : AD, that is, as the length of the given line to the height of the eye, and *bd* is the distance of the horizon-line from the point *b*, which is the picture of the foot of the line. Therefore (Theor. 2) *bc* is the required picture of the vertical line.

Fig. 9.



This problem occurs frequently in views of architecture; and a compendious method of solving it would be peculiarly convenient. For this purpose, draw a vertical line XZ at the margin of the picture, or on a separate paper, and through any point V of the horizon-line draw VX. Set off XY, the height of the vertical line, and draw VY. Then from any points *b*, *r*, on which it is required to have the pictures of lines equal to XY, draw *bs*, *rt*, parallel to the horizon-line, and draw the verticals *su*, *tv*: these have the lengths required, which may be transferred to *b* and *r*. This, with the third general construction for the base points, will save all the confusion of lines which would arise from constructing each line apart.

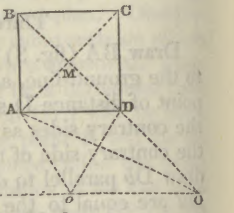
Prob. 6. *To put any sloping line in perspective.*

From the extremities of this line, suppose perpendiculars meeting the ground-plane in two points, which we shall call the base points of the sloping line. Put these base points in perspective, and draw, by last problem, the perpendiculars from the extremities. Join these by a straight line. It will be the picture required.

Prob. 7. *To put a square in perspective, as seen by a person not standing right against the middle of either of its sides, but rather nearly even with one of its corners.*

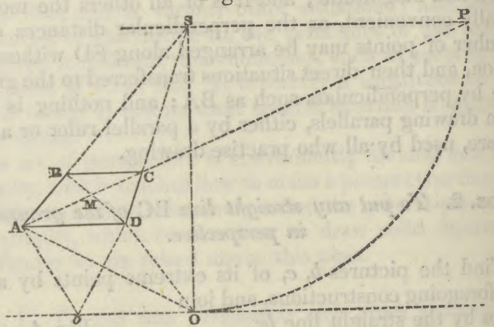
In fig. 10, let ABCD be a true square, viewed by an observer, not standing at *o*, directly against the middle of its sides AD, but at O almost even with its corner D, and viewing the side AD under the angle AOD; the angle A*o*D (under which he would have seen AD from *o*) being 60 degrees.

Fig. 10.



Make AD in fig. 11 equal to AD in fig. 10, and draw SP and O*o* parallel to AD. Then, in fig. 11, let O be the place of the observer's eye, and SO be perpendicular to SP; then S shall be the point of sight in the horizon SP.

Fig. 11.

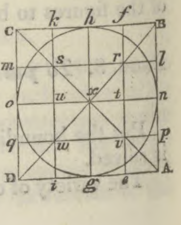


Take SO in your compasses, and set that extent from S to P; then P shall be the true point of distance, taken according to the foregoing rules.

From A and D draw the straight lines AS and DS; draw also the straight line AP, intersecting DS in C.

Lastly, through the point of intersection C draw BC parallel to AD; and ABCD in fig. 11 will be a true perspective representation of the square ABCD in fig. 10. The point M is the centre of each square, and AMC and BMD are the diagonals.

Fig. 12.



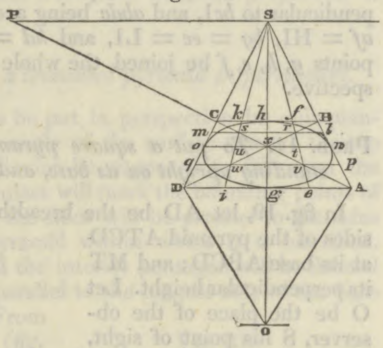
Prob. 8. *To put a reticulated square in perspective, as seen by a person standing opposite to the middle of one of its sides.*

A reticulated square is one that is divided into several little squares, like net-work, as fig. 12, each side of which is divided into four equal parts, and the whole surface into four times four (or sixteen) equal squares.

Having divided this square into the given number of lesser squares, draw the two diagonals AxC and BxD.

Make AD in fig. 13 equal to AD in fig. 12, and divide it into four equal parts, as Ae, eg, gi, and iD.

Fig. 13.



Draw SP for the horizon, parallel to AD, and, through the middle point g of AD, draw OS perpendicular to AD and SP. Make S the point of sight, and O the place of the observer's eye.

Take SP equal to SO, and P shall be the true point of distance. Draw AS and DS to the point of sight, and AP to the point of distance, intersecting DS in C: then draw BC parallel to AD, and the outlines of the reticulated square ABCD will be finished.

From the division points e, g, i, draw the straight lines ef, gh, ik, tending towards the point of sight S; and draw BD for one of the diagonals of the square, the other diagonal AC being already drawn.

Through the points r and s, where these diagonals cut ef and ik, draw lm parallel to AD. Through the centre point x, where the diagonals cut gh, draw no parallel to AD. Lastly, through the points v and w, where the diagonals cut ef and ik, draw pq parallel to AD; and the reticulated perspective square will be finished.

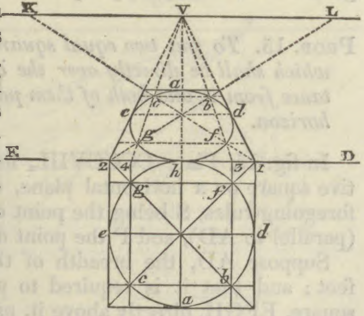
This square is truly represented, as if seen by an observer standing at O, and having his eye above the horizontal plane ABCD on which it is drawn, as if OS was the height of his eye above that plane; and the lines which form the small squares within it have the same letters of reference with those in fig. 12, which is drawn, as it would appear, to an eye placed perpendicularly above its centre x.

Prob. 9. *To put a circle in perspective.*

If a circle be viewed by an eye placed directly over its centre, it appears perfectly round; but if it be obliquely viewed, it appears of an elliptical shape. This is plain by looking at a common wine-glass set upright on a table.

Make a true reticulated square, as fig. 12, of the same diameter as you would have the circle; and setting one foot of your compasses in the centre x, describe as large a circle as the sides of the square will contain. Then, having put this reticulated square into perspective, as in fig. 13, observe through what points of the cross lines and diagonals of fig. 12 the circle passes; and through the like points in fig. 13 draw the ellipsis, which will be as true a perspective representation of the circle as the square in fig. 13 is of the square in fig. 12.

Fig. 14.

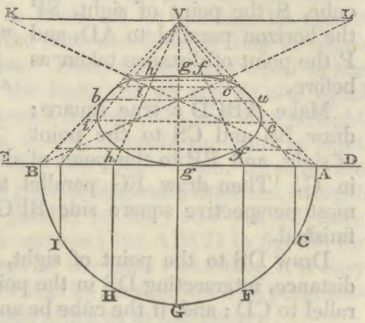


This is Mr Ferguson's rule for putting a circle in perspective; but the following rules by Wolf are perhaps more universal.

If the circle to be put in perspective be small, describe a square about it. Draw first the diagonals of the square, and then the diameters ha and de (fig. 14), cutting one another at right angles; draw the straight lines fg and bc parallel to the diameter de. Through b and f, and likewise c and g, draw straight lines meeting DE, the ground line of the picture, in the points 3 and 4. To the principal point V draw the straight lines 1V, 3V, 4V, 2V, and to the points of distance L and K, 2L and 1K. Lastly, join the points of intersection a, b, d, f, h, g, e, c, by the arcs ab, bd, df, and $abdfhgeca$ will be the circle in perspective.

If the circle be large, so as to make the foregoing practice inconvenient, bisect the ground line AB, describing, from the point of bisection as a centre, the semicircle AGB (fig. 15), and from any number of points in the circumference C, F, G, H, I, &c. draw to the ground line the perpendiculars C1, F2, G3, H4, I5, &c. From the points A, 1, 2, 3, 4, 5, B, draw straight lines to the principal point or point of sight V, likewise straight lines from B and A to the points of distance L and K. Through the common intersections draw straight lines as in the preceding case; and you will have the points a, c, f, g, h, i, b, representatives of A, C, F, G, H, I, B. Then join the points a, c, f, &c. as formerly directed, and you have the perspective circle $acfghibihgfca$.

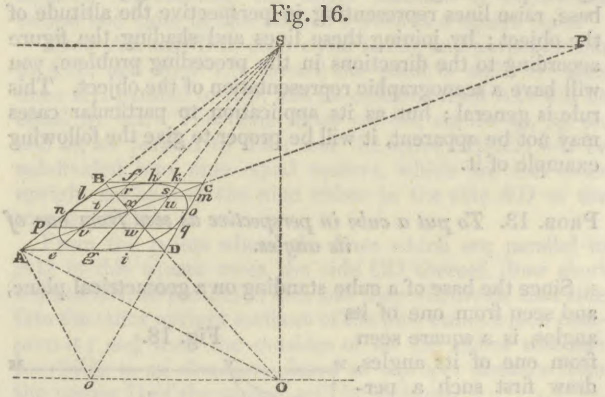
Fig. 15.



Hence it is apparent how we may put not only a circle, but also a pavement laid with stones of any form, in perspective. It is likewise apparent how useful the square is in perspective; for, as in the second case a true square was described round the circle to be put in perspective, and divided into several smaller squares, so in this third case, we make use of the semicircle only for the sake of brevity, instead of that square and circle.

Prob. 10. *To put a reticulated square in perspective, as seen by a person not standing right against the middle of either of its sides, but rather nearly even with one of its corners.*

Fig. 16.



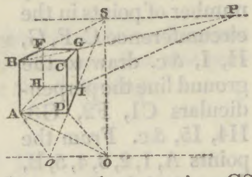
In fig. 16, let O be the place of an observer, viewing the square ABCD almost even with its corner D. Draw at pleasure SP for the horizon, parallel to AD, and make SO perpendicular to SP; then S shall be the point of sight, and P the true point of distance, if SP be made equal to SO.

Draw AS and DS to the point of sight, and AP to the point of distance, intersecting DS in the point C; then draw BC parallel to AD, and the outlines of the perspective square will be finished. This done, draw the lines which form the lesser squares, as taught in Prob. 8, and the work will be completed. You may put a perspective circle in this square by the same rule as it was done in fig. 13.

Prob. 11. *To put a cube in perspective, as if viewed by a person standing almost even with one of its edges, and seeing three of its sides.*

In fig. 17, let AB be the breadth of either of the six equal square sides of the cube AG; O the place of the observer, almost even with the edge CD of the cube, S the point of sight, SP the horizon parallel to AD, and P the point of distance taken as before.

Fig. 17.



Make ABCD a true square; draw BS and CS to the point of sight, and BP to the point of distance, intersecting CS in G. Then draw FG parallel to BC, and the uppermost perspective square side BFGC of the cube will be finished.

Draw DS to the point of sight, and AP to the point of distance, intersecting DS in the point I: then draw GI parallel to CD; and, if the cube be an opaque one, as of wood or metal, all the outlines of it will be finished; and then it may be shaded as in the figure.

But if you want a perspective view of a transparent glass cube, all the sides of which will be seen, draw AH toward the point of sight, FH parallel to BA, and HI parallel to AD: then AHID will be the square base of the cube, perspectively parallel to the top BFGC; ABFH will be the square side of the cube parallel to CGID, and FGIH will be the square side parallel to ABCD.

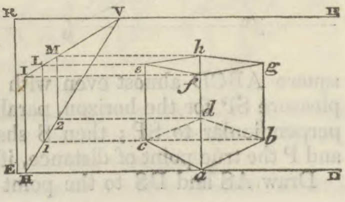
As to the shading part of the work, it is such mere children's play, in comparison of drawing the lines which form the shape of any object, that no rules need be given for it. Let a person sit with his left side toward a window, and he knows full well that if any solid body be placed on a table before him, the light will fall on the left-hand side of the body, and the right-hand side will be in the shade.

Prob. 12. *To put any solid in perspective.*

Put the base of the solid, whatever it be, in perspective by the preceding rules. From each bounding point of the base, raise lines representing in perspective the altitude of the object; by joining these lines and shading the figure according to the directions in the preceding problem, you will have a scenographic representation of the object. This rule is general; but as its application to particular cases may not be apparent, it will be proper to give the following example of it.

Prob. 13. *To put a cube in perspective as seen from one of its angles.*

Fig. 18.

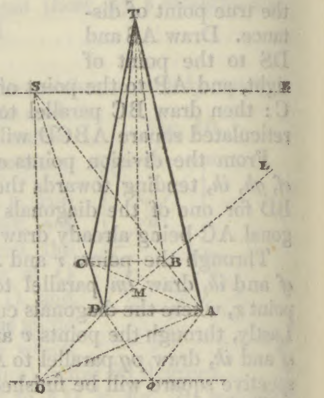


Since the base of a cube standing on a geometrical plane, and seen from one of its angles, is a square seen from one of its angles, draw first such a perspective square: then raise from any point of the ground-line DE (fig. 18) the perpendicular HI equal to the side of the square, and draw to any point V in the horizonal line HR the straight lines VI and VH. From the angles d, b, and c, draw the dotted lines $d2$ and $c1$ parallel to the ground line DE. Perpendicular to those dotted lines, and from the points 1 and 2, draw the straight lines L1 and M2. Lastly, since HI is the altitude of the intended cube in a, L1 in c and b, M2 in d, draw from the point a the straight line fa perpendicular to aE, and from the points b and c, bg and ce, perpendicular to $bc1$, and $abdc$ being according to rule, make $af = HI$, $bg = ec = L1$, and $hd = M2$. Then, if the points g, h, e, f be joined, the whole cube will be in perspective.

Prob. 14. *To put a square pyramid in perspective, as standing upright on its base, and viewed obliquely.*

In fig. 19, let AD be the breadth of either of the four sides of the pyramid ATCD at its base ABCD; and MT its perpendicular height. Let O be the place of the observer, S his point of sight, SE his horizon, parallel to AD and perpendicular to OS; and let the proper point of distance be taken in SE produced toward the left hand, as far from S as O is from S.

Fig. 19.



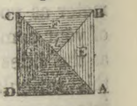
Draw AS and DS to the point of sight, and DL to the point of distance, intersecting AS in the point B. Then from B draw BC parallel to AD; and ABCD shall be the perspective square base of the pyramid.

Draw the diagonal AC, intersecting the other diagonal BD at M, and this point of intersection shall be the centre of the square base.

Draw MT perpendicular to AD, and of a length equal to the intended height of the pyramid: then draw the straight outlines AT, CT, and DT; and the outlines of the pyramid (as viewed from O) will be finished; which being done, the whole may be so shaded as to give it the appearance of a solid body.

If the observer had stood at o, he could have only seen the side ATD of the pyramid; and two is the greatest number of sides that he could see from any other place of the ground. But if he were at any height above the pyramid, and had his eye directly over its top, it would then appear as in fig. 20, and he would see all its four sides, E, F, G, H, with its top t just over the centre of its square base ABCD; which would be a true geometrical, and not a perspective square.

Fig. 20.



Prob. 15. *To put two equal squares in perspective, one of which shall be directly over the other, at any given distance from it, and both of them parallel to the plane of the horizon.*

In fig. 15, Plate CCCCVIII., let ABCD be a perspective square on a horizontal plane, drawn according to the foregoing rules, S being the point of sight, SP the horizon (parallel to AD), and P the point of distance.

Suppose AD, the breadth of this square, to be three feet; and that it is required to place just such another square, EFGH, directly above it, parallel to it, and two feet from it.

Make AE and DH perpendicular to AD, and two thirds of its length: draw EH, which will be equal and parallel

Perspective.

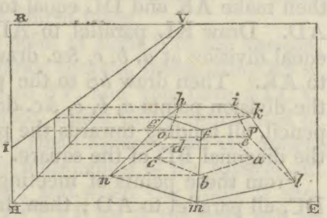
to AD; then draw ES and HS to the point of sight S, and EP to the point of distance P, intersecting HS in the point G: this done, draw FG parallel to EH; and you will have two perspective squares, ABCD and EFGH, equal and parallel to one another, the latter directly above the former, and two feet distant from it, as was required.

By this method shelves may be drawn parallel to one another, at any distance from each other in proportion to their length.

PROB. 16. *To put a truncated pyramid in perspective.*

Let the pyramid to be put in perspective be quinquangular. If from each angle of the surface whence the top is cut off, a perpendicular be supposed to fall upon the base, these perpendiculars will mark the bounding points of a pentagon, of which the sides will be parallel to the sides of the base of the pyramid within which it is inscribed. Join these points, and the interior pentagon will be formed with its longest side parallel to the longest side of the base of the pyramid. From the ground line EH (fig. 21) raise the perpendicular IH, and make it equal to the altitude of the intended pyramid. To any point V draw the straight lines IV and HV, and by a process similar to that in Prob. 16, determine the scenographical altitudes *a*, *b*, *c*, *d*, *e*. Connect the upper points *f*, *g*, *h*, *i*, *k* by straight lines; and draw *lk*, *fm*, *gn*, and the perspective of the truncated pyramid will be completed.

Fig. 21.



Cor. If in a geometrical plane two concentric circles be described, a truncated cone may be put in perspective in the same manner as a truncated pyramid.

PROB. 17. *To put in perspective a hollow prism lying on one of its sides.*

Let ABDEC (fig. 22) be a section of such a prism. Draw HI parallel to AB, and distant from it the breadth of the side on which the prism rests; and from each angle internal and external of the prism let fall perpendiculars to HI. The parallelogram will be thus divided by the ichnographical process below the ground-line, so as that the side AB of the real prism will be parallel to the corresponding side of the scenographic view of it. To determine the altitude of the internal and external angles: from H (fig. 23) raise HI perpendicular to the ground-line, and on it mark off the true altitudes H1, H2, H3, H4, and H5. Then, if from any point V in the horizon be drawn the straight lines VH, V1, V2, V3, V4, V5, or VI; by a process similar to that of the preceding problem, will be determined the height of the internal angles, viz. 1=*aa*, 2=*bb*, 4=*dd;* and of the external angles, 3=*cc* and 5 = *ee;* and when these angles are formed and put in their proper places, the scenograph of the prism is complete.

Fig. 22.

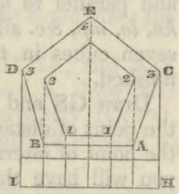


Fig. 23.

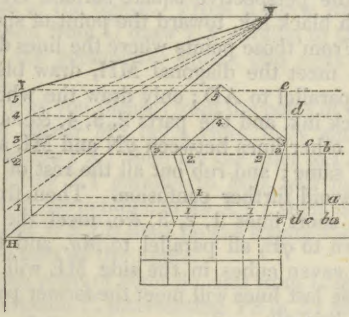

PROB. 18. *To put a square table in perspective standing on four upright square legs, of any given length with respect to the breadth of the table.*

In fig. 1, Plate CCCCVIII., let ABCD be the square part of the floor on which the table is to stand, and EFGH the surface of the square table, parallel to the floor.

Suppose the table to be three feet in breadth, and its height from the floor to be two feet; then two thirds of AD or EH will be the length of the legs *i* and *k;* the other two (*l* and *m*) being of the same length in perspective.

Having drawn the two equal and parallel squares ABCD and EFGH, as shown in Prob. 15, let the legs be square in form, and fixed into the table at a distance from its edges equal to their thickness. Take A*a* and D*d* equal to the intended thickness of the legs, and *ab* and *dc* also equal thereto. Draw the diagonals AC and BD, and draw straight lines from the points *a*, *b*, *c*, *d*, towards the point of sight S, and terminating at the side BC. Then, through the points where these lines cut the diagonals, draw the straight lines *n* and *o*, *p* and *q*, parallel to AD; and you will have formed four perspective squares (like ABCD in fig. 19) for the bases of the four legs of the table: and then it is easy to draw the four upright legs by parallel lines, all perpendicular to AD, and to shade them as in the figure.

To represent the intended thickness of the table-board, draw *eh* parallel to EH, and HG toward the point of sight S: then shade the spaces between these lines, and the perspective figure of the table will be finished.

PROB. 19. *To put five square pyramids in perspective, standing upright on a square pavement composed of the surfaces of eighty-one cubes.*

In fig. 1, Plate CCCCVI., let ABCD be a perspective square drawn according to the foregoing rules, S the point of sight, P the point of distance in the horizon PS, and AC and BD the two diagonals of the square.

Divide the side AD into nine equal parts (because 9 times 9 is 81) as A*a*, *ab*, *bc*, &c. and from these points of division *a*, *b*, *c*, *d*, &c. draw lines toward the point of sight S, terminating at the furthermost side BC of the square. Then, through the points where these lines cut the diagonals, draw straight lines parallel to AD, and the perspective square ABCD will be subdivided into eighty-one lesser squares, representing the upper surfaces of eighty-one cubes, laid close to one another's sides in a square form.

Draw AK and DL, each equal to A*a*, and perpendicular to AD; and draw LN toward the point of sight S: then draw KL parallel to AD, and its distance from AD will be equal to A*a*. This done, draw *al*, *bm*, *cn*, *do*, *ep*, *fq*, *gr*, and *hs*, all parallel to AK; and the space ADKL will be subdivided into nine equal squares, which are the outer upright surfaces of the nine cubes in the side AD of the square ABCD.

From the points where the lines which are parallel to AD in this square meet the side CD thereof, draw short lines to LN, all parallel to DL, and they will divide that side into the outer upright surfaces of the nine cubes which compose it; and then the outsides of all the cubes that can be visible to an observer, placed at a proper distance from the corner D of the square, will be finished.

As taught in Prob. 14, place the pyramid AE upright on its square base A*tva*, making it as high as you please; and the pyramid DH on its square base *huw*D, of equal height with AE.

Draw EH from the top of one of these pyramids to the top of the other; and EH will be parallel to AD.

Draw ES and HS to the point of sight S, and HP to the point of distance P, intersecting ES in F.

From the point F draw FG parallel to EH; then draw EG, and you will have a perspective square EFGH (parallel to ABCD) with its two diagonals EG and FH intersecting one another in the centre of the square at I. The four corners of this square, E, F, G, H, give the perspective heights of the four pyramids AE, BF, CG, and DH; and the intersection I of the diagonals gives the height of the pyramid MI, the centre of whose base is the centre of the perspective square ABCD.

Lastly, place the three pyramids BF, CG, MI, upright on their perspective bases at B, C, and M; and the required perspective representation will be finished as in the figure.

Prob. 20. *To put upright pyramids in perspective, on the sides of an oblong square or parallelogram, so that their distances from one another shall be equal to the breadth of the parallelogram.*

In most of the foregoing operations we have considered the observer to be so placed as to have an oblique view of the perspective objects: in this we shall suppose him to have a direct view of fig. 2, Plate CCCCVI., that is, standing right against the middle of the end AD which is nearest to his eye, and viewing AD under an angle of 60 degrees.

Having cut AD in the middle, by the perpendicular line S*s*, take S therein at pleasure for the point of sight, and draw ES for the horizon, parallel to AD. Here S*s* must be supposed to be produced downward, below the limits of the plate, to the place of the observer; and SE to be produced towards the left hand beyond E, far enough to take a proper point of distance therein, according to the foregoing rules.

Take A*d* at pleasure, and D*g* equal to A*d*, for the breadths of the square bases of the two pyramids AE and DF next the eye: then draw AS and *d*S, and likewise DS and *g*S, to the point of sight S; and DG on to the point of distance, intersecting AS in G: then from G draw GI parallel to AD; you will have the first perspective square AGID of the parallelogram ABCD.

From I draw IH to (or toward) the point of distance, intersecting AS in H: then, from H draw HK parallel to AD, and you will have the second perspective square GHKI of the parallelogram. Go on in this manner till you have drawn as many perspective squares up toward S as you please.

Through the point *e*, where DG intersects *g*S, draw *bf* parallel to AD; and you will have formed the two perspective square bases A*bcd* and *ef*D*g* of the two pyramids at A and D.

From the point *f* (the upper outward corner of *ef*D*g*) draw *fh* toward the point of distance, till it meets AS in *h*; then from this point of meeting draw *hm* parallel to GI, and you will have formed the two perspective squares G*hik* and *lm*I*n*, for the square bases of the two pyramids at G and I.

Proceed in the same manner to find the bases of all the other pyramids, at the corners of the rest of the perspective squares in the parallelogram ABCD, as shown by the figure. Then,

Having placed the first two pyramids at A and D upright on their square bases, as shown in Prob. 9, and made them of any equal heights at pleasure, draw ES and FS from the tops of these pyramids to the point of sight S: place all the rest of the pyramids upright on their respective bases, making their tops touch the straight lines ES and FS; and all the work, except the shading part, will be finished.

Prob. 21. *To put a square pyramid of equal-sized cubes in perspective.*

Fig. 3, Plate CCCCVI., represents a pyramid of this kind, consisting, as it were, of square tables of cubes, one table above another; 81 in the lowest, 49 in the next, 25 in the third, 9 in the fourth, and 1 in the fifth or uppermost. These are the square numbers of 9, 7, 5, 3, and 1.

If the artist is already master of all the preceding operations, he will find less difficulty in this than in attending to the following description of it; for it cannot be described in a few words, but may be executed in a very short time.

In fig. 4, Plate CCCCVI., having drawn PS for the horizon, and taken S for the point of sight therein (the observer being at O), draw AD parallel to PS for the side (next the eye) of the first or lowermost table of cubes. Draw AS and DS to the point of sight S, and DP to the point of distance P, intersecting AS in the point B. Then, from B draw BC parallel to AD, and you will have the surface ABCD of the first table.

Divide AD into nine equal parts, as A*a*, *ab*, *bc*, *cd*, &c. then make AK and DL equal to A*a*, and perpendicular to AD. Draw KL parallel to AD, and from the points of equal division at *a*, *b*, *c*, &c. draw lines to KL, all parallel to AK. Then draw *h*S to the point of sight S, and from the division points *a*, *b*, *c*, &c. draw lines with a black-lead pencil, all tending towards the point of sight, till they meet the diagonal BD of the square.

From these points of meeting draw black-lead lines to DC, all parallel to AD; then draw the parts of these lines with black ink which are marked 1, 2, 3, 4, &c. between *h*E and DC.

Having drawn the first of these lines βq with black ink, draw the parts *ai*, *bk*, *cl*, &c. (of the former lines which met the diagonal BD) with black ink also; and rub out the rest of the black-lead lines, which would otherwise confuse the following part of the work. Then draw LF toward the point of sight S; and from the points where the lines 1, 2, 3, 4, &c. meet the line DC, draw lines down to LF, all parallel to DL; and all the visible lines between the cubes in the first table will be finished.

Make *i*G equal and perpendicular to βi, and *q*M equal and parallel to *i*G; then draw GM, which will be equal and parallel to *iq*. From the points *k*, *l*, *m*, *n*, &c. draw *kn*, *lo*, *mp*, &c. all parallel to *i*G, and the outsides of the seven cubes in the side G*q* of the second table will be finished.

Draw GS and MS to the point of sight S, and MP to the point of distance P, intersecting GS in H; then, from the point of intersection H, draw HI parallel to AD; and you will have the surface GHIM of the second table of cubes.

From the points *n*, *o*, *p*, *q*, &c. draw black-lead lines toward the point of sight S, till they meet the diagonal MH of the perspective square surface GHIM; and draw SM, with black ink, toward the point of sight.

From those points where the lines drawn from *n*, *o*, *p*, *q*, &c. meet the diagonal MH, draw black-lead lines to MI, all parallel to AD; only draw the whole first line $\gamma 1$ with black ink, and the parts 2, 3, 4, &c. and *nt*, *ou*, *pv*, &c. of the other lines between *y*N and MI, and GM and $\gamma 1$, with the same; and rub out all the rest of the black-lead lines, to avoid further confusion. Then from the points where the short lines 1, 2, 3, &c. meet the line MI, draw lines down to *q*E, all parallel to M*q*, and the outer surfaces of the seven cubes in the side ME will be finished; and all these last lines will meet the former parallels 2, 3, 4, &c. in the line *q*E.

Make *t*O equal and perpendicular to γt, and *y*P equal and parallel to *t*O; then draw OP, which will be equal and parallel to *ty*. This done, draw OS and PS to the point of sight S, and PP to the point of distance P in the horizon. Lastly, from the point Q, where PP intersects OS, draw QR parallel to OP; and you will have the outlines OQRP of the surface of the third perspective table of cubes.

From the points *u*, *v*, *w*, *x*, draw upright lines to OP, all parallel to *t*O, and you will have the outer surfaces of the five cubes in the sides O*y* of this third table.

From the points where these upright lines meet OP, draw lines toward the point of sight S, till they meet the diagonal PQ; and from these points of meeting draw lines to PR, all parallel to OP, making the parts 2, 3, 4, 5, of these lines with black ink which lie between ZY and PR. Then, from the points where these lines meet PR, draw lines down to *y*N, which will bound the outer surfaces of the five cubes in the side PN of the third table.

Draw the line δ1 with black ink; and, at a fourth part of its length between δ and Z, draw an upright line to S, equal in length to that fourth part, and another equal and parallel thereto from Z to V: then draw SV parallel to δZ, and draw the two upright and equidistant lines between δZ and SV, and you will have the outer surfaces of the three cubes in the side SZ of the fourth table.

Draw SS and VS to the point of sight S in the horizon, and VP to the point of distance therein, intersecting SS in T; then draw TU parallel to SV, and you have STUV, the surface of the fourth table, which being reticulated or divided into nine perspective small squares, and the uppermost cube W placed on the middlemost of the squares, all the outlines will be finished; and when the whole is properly shaded, as in Plate CCCCVI. fig. 3, the work will be done.

Prob. 22. *To represent a double cross in perspective.*

In fig. 5, Plate CCCCVI., let ABCD and EFGH be the two perspective squares, equal and parallel to one another, the uppermost directly above the lowermost, drawn by the rules already laid down, and as far asunder as is equal to the given height of the upright part of the cross; S being the point of sight, and P the point of distance, in the horizon PS taken parallel to AD.

Draw AE, DH, and CG; then AEHD and DHGC shall be the two visible sides of the upright part of the cross; of which the length AE is here made equal to three times the breadth EH.

Divide DH into three equal parts, HI, IK, and KD. Through these points of division, at I and K, draw MO and PR parallel to AD; and make the parts MN, IO, PQ, KR, each equal to HI; then draw MP and OR parallel to DH.

From M and O draw MS and OS to the point of sight S; and from the point of distance P draw PN, cutting MS in T: from T draw TU parallel to MO, and meeting OS in U; and you will have the uppermost surface MTUO of one of the cross pieces of the figure. From R draw RS to the point of sight S; and from U draw UV parallel to OR; and OUVR shall be the perspective square end next the eye of that cross part.

Draw PMX (as long as you please) from the point of distance P, through the corner M; lay a ruler to N and S, and draw XN from the line PX: then lay the ruler to I and S, and draw YZS. Draw XY parallel to MO, and make XW and YB equal and perpendicular to XY: then draw WB parallel to XY, and WXYB shall be the square visible end of the other cross part of the figure.

Draw BK toward the point of sight S; and from U draw UP to the point of distance P, intersecting YS in Z: then, from the intersection Z draw Z*a* parallel to MO, and Z*b* parallel to HD, and the whole delineation will be finished.

This done, shade the whole, as in fig 6, Plate CCCCVI., and you will have a true perspective representation of a double cross.

Prob. 23. *To put three rows of upright square objects in perspective, equal in size, and at equal distances from each other, on an oblong square plane, the breadth of which shall be of any assigned proportion to the length thereof.*

Fig. 7, Plate CCCCVI., is a perspective representation of an oblong square plane, three times as long as it is broad, having a row of nine upright square objects on each side, and one of the same number in the middle; all equally high, and at equal distances from one another, both longwise and crosswise, on the same plane.

In fig. 8, Plate CCCCVI., PS is the horizon, S the point of sight, P the point of distance, and AD (parallel to PS) the breadth of the plane.

Draw AS, NS, and DS, to the point of sight S; the point N being in the middle of the line AD: and draw DP to the point of distance P, intersecting at AS in the point B: then, from B draw BC parallel to AD, and you have the perspective square ABCD.

Through the point *i*, where DB intersects NS, draw *ae* parallel to AD; and you will have subdivided the perspective square ABCD into four lesser squares, as *ai*N, N*ie*D, *a*B*ki*, and *ik*C*e*.

From the point C (at the top of the perspective square ABCD) draw CP to the point of distance P, intersecting AS in E; then from the point E draw EF parallel to AD; and you will have the second perspective square BEFC.

Through the point *l*, where CE intersects NS, draw *bf* parallel to AD; and you will have subdivided the square BEFC into the four squares B*blk*, *klf*C, *b*E*ml*, and *lm*F*f*.

From the point F (at the top of the perspective square BEFC) draw FP to the point of distance P, intersecting AS in I; then from the point I draw IK parallel to AD; and you will have the third perspective square EIKF.

Through the point *n*, where FI intersects NS, draw *cg* parallel to AD; and you will have subdivided the square EIKF into four lesser squares, E*cnm*, *mng*F, *c*I*on*, and *no*K*g*.

From the point K (at the top of the third perspective square EIKF) draw KP to the point of distance P, intersecting AS in L; then from the point L draw LM parallel to AD; and you will have the fourth perspective square ILMK.

Through the point *p*, where KL intersects NS, draw *dh* parallel to AD; and you will have subdivided the square ILMK into the four lesser squares I*dpo*, *oph*K, *d*L*qp*, and *pq*M*h*.

Thus we have formed an oblong square ALMD, whose perspective length is equal to four times its breadth, and it contains sixteen equal perspective squares. If greater length was still wanted, we might proceed farther on toward S.

Take A3, equal to the intended breadth of the side of the upright square object AQ (all the other sides being of the same breadth), and AO for the intended height. Draw O 18 parallel to AD, and make D 8 and 4 7 equal to A 3; then draw 3 S, 4 S, 7 S, and 8 S to the point of sight S; and among them we shall have the perspective square bases of all the twenty-seven upright objects on the plane.

Through the point 9, where DB intersects 8 S, draw 1 10 parallel to AD, and you have the three perspective square bases A 1 2 3, 4 5 6 7, 8 9 10 D, of the three upright square objects at A, N, and D.

Through the point 21, where *eb* intersects 8 S, draw 14, 11 parallel to AD; and you will have the three perspective squares *a* 14 15 16 17 18 19 20, and 21 11 *e* 22, for the bases of the second cross row of objects; namely, the next beyond the first three at A, N, and D.

Through the point *w*, where CE intersects 8 S, draw a line parallel to BC; and you will have three perspective squares, at B, *k*, and C, for the bases of the third row of objects; one of which is set up at B.

Through the point *x*, where *fc* intersects 8 S, draw a line parallel to *bf;* and you will have three perspective squares, at *b*, *l*, and *x*, for the bases of the fourth cross row of objects.

Go on in this manner, as you see in the figure, to find the rest of the square bases, up to LM; and you will have 27 upon the whole oblong square plane, on which you are to place the like number of objects, as in fig. 7, Plate CCCCVI.

Having assumed AO for the perspective height of the three objects at A, N, and D (Plate CCCCVI. fig. 8) next the observer's eye, and drawn O 18 parallel to AD, in order to make the objects at N and D of the same height as that at O; and having drawn the upright lines 4 15, 7 W, 8 X, and D 22, for the heights at N and D; draw OS and RS, 15 S and WS, XS and 22 S, all to the point of sight S; and these lines will determine the perspectively equal heights of all the rest of the upright objects, as shown by the two placed at *a* and B.

To draw the square tops of these objects, equal and parallel to their bases, we need only give one example, which will serve for all.

Draw 3 R and 2 Q parallel to AO, and up to the line RS; then draw PQ parallel to OR, and OPQR shall be the top of the object at A, equal and parallel to its square base A 1 2 3. In the same easy way the tops of all the other objects are formed.

When all the rest of the objects are delineated, shade them properly, and the whole perspective scheme will have the appearance of fig. 7, Plate CCCCVI.

PROB. 24. *To put a square box in perspective, containing a given number of lesser square boxes of a depth equal to their width.*

Let the given number of little square boxes or cells be sixteen; then four of them make the length of each side of the four outer sides *ab*, *bc*, *cd*, *da*, as in Plate CCCCVII. fig. 9, and the depth *af* is equal to the width *ae*. Whoever can draw the reticulated square by the rules laid down towards the beginning of this article, will be at no loss about putting this perspective scheme in practice.

PROB. 25. *To put stairs with equal and parallel steps in perspective.*

In fig. 10, Plate CCCCVII., let *ab* be the given breadth of each step, and *ai* the height thereof. Make *bc*, *cd*, *de*, &c. each equal to *ab*, and draw all the upright lines *ai*, *bl*, *cn*, *dp*, &c. perpendicular to *ah* (to which the horizon *s*S is parallel); and from the points *i*, *l*, *n*, *p*, *r*, &c. draw the equidistant lines *i*B, *l*C, *n*D, &c. parallel to *ah;* these distances being equal to that of *i*B from *ah*.

Draw *xi* touching all the corner-points *l*, *n*, *p*, *r*, *t*, *v;* and draw 2 16 parallel to *xi*, as far from it as you want the length of the steps to be.

Toward the point of sight S draw the lines *a*1, *i*2, *k*3, *l*4, &c. and draw 16 15, 14 13, 12 11, 10 9, 8 7, 6 5, 4 3, and 2 1, all parallel to A*h*, and meeting the lines *w* 15, *u* 13, *s* 11, &c. in the points 15, 13, 11, 9, 7, 5, 3, and 1: then from these points draw 15 14, 13 12, 11 10, 9 8, 7 6, 5 4, and 3 2, all parallel to *ha;* and the outlines of the steps will be finished. From the point 16 draw 16 A parallel to *ha*, and A*x* 16 will be the part of the flat at the top of the uppermost step. This done, shade the work as in fig. 11, Plate CCCCVII., and the whole will be finished.

PROB. 26. *To put stairs with flats and opening in perspective, standing on a horizontal pavement of squares.*

In fig. 12, Plate CCCCVII., having made S the point of sight, and drawn a reticulated pavement AB with black-lead lines, which may be rubbed out again; at any distance from the side AB of the pavement which is nearest to the eye, and at any point where you choose to begin the stair at that distance, as *a*, draw G*a* parallel to BA, and take *ab* at pleasure for the height of each step.

Take *ab* in your compasses, and set that extent as many times upward from F to E as is equal to the first required number of steps O, N, M, L, K; and from these points of division in EF draw 1*b*, 2*d*, 3*f*, 4*h*, and E*k*, all equidistant from one another, and parallel to F*a;* then draw the equidistant upright lines *ab*, *td*, *uf*, *vh*, *wk*, and I*m*, all perpendicular to F*a;* then draw *mb*, touching the outer corners of these steps at *m*, *k*, *h*, *f*, *d*, and *b;* and draw *ns* parallel to *mb*, as far from it as you want the length of the steps K, L, M, N, O to be.

Towards the point of sight S draw *mn*, *l*5, *ko*, *i*6, *hp*, *fq*, *dr*, and *bs*. Then (parallel to the bottom-line BA) through the points *n*, *o*, *p*, *q*, *r*, *s*, draw *n*8; 5, 14; 6, 15; 7, 16; 1, 17; and 2*s;* which done, draw *n*5 and *o*6 parallel to *lm*, and the outlines of the steps K, L, M, N, O will be finished.

At equal distances with that between the lines marked 8 and 14, draw the parallel lines above, marked 9, 10, 11, 12, and 13; and draw perpendicular lines upwards from the points *n*, *o*, *p*, *q*, *r*, *s*, as in the figure.

Make H*m* equal to the intended breadth of the flat above the square opening at the left hand, and draw HW toward the point of sight S, equal to the intended length of the flat; then draw WP parallel to H*m*, and the outlines of the flat will be finished.

Take the width of the opening at pleasure, as from F to C, and draw CD equal and parallel to FE. Draw GH parallel to CD, and the short lines marked 33, 34, &c. just even with the parallel lines 1, 2, &c. From the points where these short lines meet CD, draw lines toward the point of sight S till they meet DE; then from the points where the lines 38, 39, 40, &c. of the pavement meet C*y*, draw upright lines parallel to CD; and the lines which form the opening will be finished.

The steps P, Q, R, S, T, and the flat U above the arch V, are done in the same manner with those in fig. 10, as taught in Prob. 25, and the equidistant parallel lines marked 18, 19, &c. are directly even with those on the left-hand side of the arch V, and the upright lines on the right-hand side are equidistant with those on the left.

From the points where the lines 18, 19, 20, &c. meet the right-hand side of the arch, draw lines toward the point of sight S; and from the points where the pavement lines 29, 30, 31, 32, meet the line drawn from A towards the point of sight, draw upright lines toward the top of the arch.

Having done the top of the arch, as in the figure, and the few steps to the right hand thereof, shade the whole, as in fig. 13, Plate CCCCVII., and the work will be finished.

PROB. 27. *To put upright conical objects in perspective, as if standing on the sides of an oblong square, at distances from one another equal to the breadth of the oblong.*

In fig. 14, Plate CCCCVII., the bases of the upright cones are perspective circles inscribed in squares of the same diameter; and the cones are set upright on their bases by the same rules as are given for pyramids, which we need not repeat here.

In most of the foregoing operations we have considered the observer's eye to be above the level of the tops of all the objects, as if he viewed them when standing on high ground. In this figure, and in fig. 17 and fig. 18, Plate CCCCVIII., we shall suppose him to be standing on low ground, and the tops of the objects to be above the level of his eye.

In fig. 14, Plate CCCCVII., let AD be the perspective breadth of the oblong square ABCD; and let A*a* and D*d* (equal to A*a*) be taken for the diameters of the circular bases of the two cones next the eye, whose intended equal heights shall be AE and DF.

Having made S the point of sight in the horizon parallel to AD, and found the proper point of distance therein, draw AS and *a*S to contain the bases of the cones on the left-hand side, and DS and *d*S for those on the right.

Having made the two first cones at A and D of equal height at pleasure, draw ES and FS from their tops to the point of sight, for limiting the perspective heights of all the rest of the cones. Then divide the parallelogram ABCD into as many equal perspective squares as you please; find the bases of the cones at the corners of these squares, and make the cones thereon, as in the figure.

If you would represent a ceiling equal and parallel to ABCD, supported on the tops of these cones, draw EF, then EFGH shall be the ceiling; and by drawing *ef* parallel to EF, you will have the thickness of the floor-boards and beams, which may be what you please.

This shows how any number of equidistant pillars may be drawn of equal heights to support the ceiling of a long room, and how the walls of such a room may be represented in perspective at the backs of these pillars. It also shows how a street of houses may be drawn in perspective.

Prob. 28. *To put a square hollow in perspective, the depth of which shall bear any assigned proportion to its width.*

Fig. 17, Plate CCCCVIII., is the representation of a square hollow, of which the depth AG is equal to three times its width AD; and S is the point of sight over which the observer's eye is supposed to be placed, looking perpendicularly down into it, but not directly over the middle.

Draw AS and DS to the point of sight S; make ST the horizon parallel to AD, and produce it to such a length beyond T that you may find a point of distance therein not nearer S than if AD were seen under an angle of sixty degrees.

Draw DU to the point of distance, intersecting AS in B; then from the point B draw BC parallel to AD; and you will have the first perspective square ABCD, equal to a third part of the intended depth.

Draw CV to the point of distance, intersecting AS in E; then from the point E draw EF parallel to AD; and you will have the second perspective square BEFC, which, added to the former one, makes two thirds of the intended depth.

Draw FW to the point of distance, intersecting AS in G; then from the point G draw GH parallel to AD; and you will have the third perspective square EGHF, which, with the former two, makes the whole depth AGHD three times as great as the width AD, in a perspective view.

Divide AD into any number of equal parts, as suppose 8; and from the division points *a*, *b*, *c*, *d*, &c. draw lines toward the point of sight S, and ending at GH; then through the points where the diagonals BD, EC, GF, cut these lines, draw lines parallel to AD; and you will have the parallelogram AGHD reticulated, or divided into 192 small and equal perspective squares.

Make AI and DM equal and perpendicular to AD; then draw IM, which will be equal and parallel to AD; and draw IS and MS to the point of sight S.

Divide AI, IM, and MD into the same number of equal parts as AD is divided; and from these points of division draw lines toward the point of sight S, ending respectively at GK, KL, and LH.

From those points where the lines parallel to AD meet AG and DH, draw upright lines parallel to AI and DM; and from the points where these lines meet IK and LM draw lines parallel to IM; then shade the work, as in the figure.

Prob. 29. *To represent a semicircular arch in perspective, as if it were standing on two upright walls, equal in height to the height of the observer's eye.*

After having gone through the preceding operation, this will be more easy by a bare view of fig. 18, Plate CCCCVIII., than it could be made by any description; the method being so much like that of drawing and shading the square hollow. We need only mention, that *a*T*b*EA and DF*ctd* are the upright walls on which the semicircular arch is built; that S is the point of sight in the horizon T*t*, taken in the centre of the arch; and *d* in fig. 17 is the point of distance; and that the two perspective squares ABCD and BEFC make the parallelogram AEFD of a length equal to twice its breadth AD.

Prob. 30. *To represent a square in perspective, as viewed by an observer standing directly even with one of its corners.*

In fig. 19, Plate CCCCVIII., let A9BC be a true square, viewed by an observer standing at some distance from the corner C, and just even with the diagonal C9.

Let *p*SP be the horizon, parallel to the diagonal AB; and S the point of sight, even with the diagonal C9. Here it will be proper to have two points of distance, *p* and P, equidistant from the point of sight S.

Draw the straight line 1 17 parallel to AB, and draw A8 and B10 parallel to CS. Take the distance between 8 and 9 in your compasses, and set it off all the way in equal parts from 8 to 1, and from 10 to 17. The line 1 17 should be produced a good way farther both to right and left hand from 9, and divided all the way in the same manner.

From these points of equal division, 8, 9, 10, &c. draw lines to the point of sight S, and also to the two points of distance *p* and P, as in the figure.

Now it is plain that *acb*9 is the perspective representation of A9BC, viewed by an observer even with the corner C and diagonal C9. But if there are other such squares lying even with this, and having the same position with respect to the line 1 17, it is evident that the observer, who stands directly even with the corner C of the first square, will not be even with the like corners G and K of the others; but will have an oblique view of them, over the sides FG and IK, which are nearest his eye: and their perspective representations will be *egf*6 and *hki*3, drawn among the lines in the figure; of which the spaces taken up by each side lie between three of the lines drawn toward the point of distance *p*, and three drawn to the other point of distance P.

Prob. 31. *To represent a common chair, in an oblique perspective view.*

The original lines to the point of sight S, and points of distance *p* and P (Plate CCCCVIII. fig. 19), being drawn as in the preceding operation, choose any part of the plane, as *lmn*13, on which you would have the chair L to stand. There are just as many lines (namely two) between *l* and *m* or 13 and *n*, drawn toward the point of distance *p*, at the left hand, as between *l* and 13, or *m* and *n*, drawn to the point of distance P on the right: so that *lm*, *mn*, *n*13, and 13*l*, form a perspective square.

From the four corners *l*, *m*, *n*, 13, of this square raise the four legs of the chair to the perspective perpendicular height you would have them: then make the seat of the chair a square equal and parallel to *lmn*13, as taught in Prob. 15, which will make the two sides of the seat in the direction of the lines drawn toward the point of distance *p*, and the fore and back part of the seat in direction of the lines drawn to the other point of distance P. This done, draw the back of the chair leaning a little backward, and the cross bars therein tending toward the point of distance P. Then shade the work as in the figure, and the perspective chair will be finished.

Prob. 32. *To present an oblong square table in an oblique perspective view.*

In fig. 19, Plate CCCCVIII., M is an oblong square table, as seen by an observer standing directly even with C9 (see Prob. 30), the side next the eye being perspectively parallel to the side *ac* of the square *abc*9. The forementioned lines drawn from the line 1 17 to the two points of distance *p* and P, form equal perspective squares on the ground plane.

Choose any part of this plane of squares for the feet of the table to stand upon; as at *p*, *q*, *r*, and *s*, in direction of the lines *op* and *rs* for the two long sides, and *ts* and *qr* for the two ends; and you will have the oblong square or parallelogram *qrst* for the part of the floor or ground-plane whereon the table is to stand: and the breadth of this plane is here taken in proportion to the length as 6 to 10; so that, if the length of the table be ten feet, its breadth will be six.

On the four little perspective squares at *q*, *r*, *s*, and *t*, place the four upright legs of the table, of what height you please, so that the height of the two next the eye, at *o* and *p*, shall be terminated by a straight line *uv* drawn to the point of distance P. This done, make the leaf M of the table an oblong square, perspectively equal and parallel to the oblong square *qrst* on which the feet of the table stands. Then shade the whole, as in the figure, and the work will be finished.

If the line 1 17 were prolonged to the right and left hand, and equally divided throughout (as it is from 1 to 17), and if the lines which are drawn from *p* and P to the right and left hand sides of the plate were prolonged till they came to the extended line 1 17, they would meet it in the equal points of division. In forming large plans of this sort, the ends of slips of paper may be pasted to the right and left edges of the sheet on which the plan is to be formed.

Of the Anamorphosis, or reformation of distorted images.

By this means, pictures that are so mishapen as to exhibit no regular appearance of any thing to the naked eye, shall, when viewed by reflection, present a regular and beautiful image. The inventor of this ingenious device is not known. Simon Stevinus, who was the first that wrote upon it, does not inform us from whom he learned it. The principles of it are laid down by S. Vauzelard, in his *Perspective Conique et Cylindrique*; and Gaspar Schott professes to copy Marius Bettinus in his description of this piece of artificial magic.

It will be sufficient for our purpose to copy one of the simplest figures of this writer, as by this means the mystery of this art will be sufficiently unfolded. Upon the cylinder of paper, or pasteboard, ABCD, fig. 16, Plate CCCCVIII., draw whatever is intended to be exhibited, as the letters IHS. Then with a needle make perforations along the whole outline; and placing a candle G behind this cylinder, mark upon the ground-plane the shadow of them, which will be distorted more or less, according to the position of the candle or the plane, &c. This being done, let the picture be an exact copy of this distorted image, let a metallic speculum be substituted in the place of the cylinder, and let the eye of the spectator have the same position before the cylinder that the candle had behind it. Then looking upon the speculum, he will see the distorted image restored to its proper shape. The reformation of the image, he says, will not easily be made exact in this method, but it will be sufficiently so to answer the purpose.

Other methods, more exact and geometrical than this, were found out afterwards: so that these pictures could be drawn by certain rules, without the use of a candle. Schott quotes one of these methods from Bettinus, another from Herigonius, and another from Kircher, which may be seen in his *Magia*, vol. i. p. 162, &c. He also gives an account of the methods of reforming pictures by speculums of conical and other figures.

Instead of copying any of these methods from Schott or Bettinus, we shall present our readers with that which Dr Smith hath given us in his Optics, vol. i. p. 250, as, no doubt, the best, and from which any person may easily make a drawing of this kind. The same description answers to two mirrors, one of which, fig. 24, is convex, and the other, fig. 25, is concave.

Fig. 24.

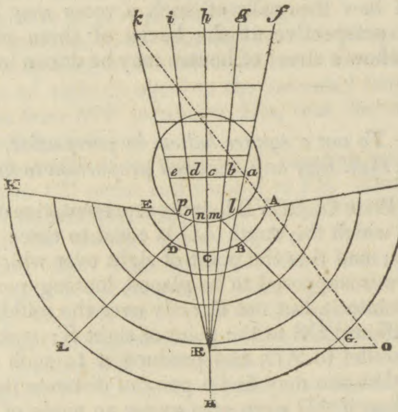

Fig. 25.

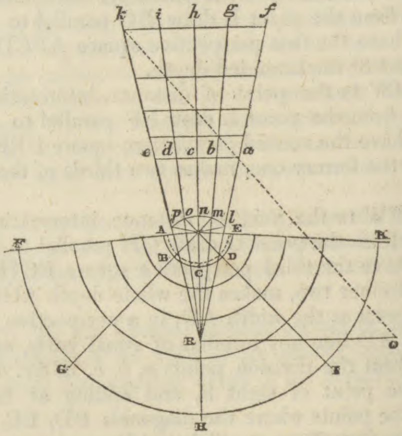

In order to paint upon a plane a deformed copy, ABCDEKIHGF, of an original picture, which shall appear regular when seen from a given point O, elevated above the plane, by rays reflected from a polished cylinder, placed upon the circle *lnp*, equal to its given base; from the point R, which must be supposed to lie perpendicularly under O, the place of the eye, draw two lines R*a*, R*e*, which shall either touch the base of the cylinder, or else cut off two small equal segments from the sides of it, according as the copy is intended to be more or less deformed. Then, taking the eye, raised above R, to the given height RO, somewhat greater than that of the cylinder, for a luminous point, describe the shadow *aekf* (of a square, fig. 24, or parallelogram standing upright upon *ae* as a base, and containing the picture required) anywhere behind the arch *lnp*. Let the lines drawn from R to the extremities and divisions of the base *a*, *b*, *c*, *d*, *e*, cut the remotest part of the shadow in the points *f*, *g*, *h*, *i*, *k*, and the arch of the base in *l*, *m*, *n*, *o*, *p*; from which points draw the lines *l*AF, *m*BG, *n*CH, *o*DI, *p*EK, as if they were rays of light that came from the focus R, and were reflected from the base *lnp*; so that each couple, *l*A, *l*R, produced, may cut off equal segments from the circle. Lastly, transfer the lines *laf*, *mbg*, &c. and all their parts in the same order, upon the respective lines *l*AF, *m*BG, &c. and having drawn regular curves, by estimation, through the points A, B, C, D, E, through F, G, H, I, K, and through every intermediate order of points; the figure ACEKHF, so divided, will be the deformed copy of the square, drawn and divided upon the original picture, and will appear similar to it, when seen in the polished cylinder, placed upon the base *lnp*, by the eye in its given place O.

The practical methods of drawing these images seem to have been carried to the greatest perfection by J. Leopold, who, in the *Acta Lipsiensia* for the year 1712, has described two machines, one for the images to be viewed with a cylindrical and the other with a conical mirror. The person possessed of this instrument has nothing to do but to take any print he pleases, and while he goes over the outlines of it with one pen, another traces the anamorphosis.

By methods of this kind, groves of trees may be cut, so as to represent the appearance of men, horses, and other objects, from some one point of view, which are not at all discernible in any other. This might easily be effected by one person placing himself in any particular situation, and giving directions to other persons what trees to lop, and in what manner. In the same method it has been contrived, that buildings of circular and other forms, and also whole groups of buildings consisting of walls at different distances, and with different positions to one another, should be painted so as to exhibit the exact representation of particular objects, which could only be perceived in one situation. Bettinus has illustrated this method by drawings in his *Apiaria*.

It may appear a bold assertion to say, that the very short sketch now given of the art of perspective is a sufficient foundation for the whole practice, and includes *all* the expeditious rules peculiar to the problems which most generally occur. It is, however, true; and the intelligent reader will perceive, that the two theorems on which the whole rests include every possible case, and apply with equal facility to pictures and originals in any position, although the examples are selected of perpendicular pictures, and of originals referred to horizontal planes, as being the most frequent. The scientific foundation being so simple, the structure need not be complex, nor swell into such volumes as have been published on the subject; which by their size deter from the perusal, and give the simple art the appearance of intricate mystery, whilst, by their prices, they defeat the design of their authors to promote the dissemination of knowledge amongst practitioners. The treatises on perspective acquire their bulk by long and tedious discourses, minute explanations of common things, or by great numbers of examples; which indeed render some of these books valuable from the variety of curious cuts, but do not at all instruct the reader by any improvements made in the art itself. For it is evident that most of those who have treated this subject have been more conversant in the practice of designing than in the principles of geometry; and therefore when, in their practice, the cases which have occurred put them upon trying particular expedients, they have thought them worth communicating to the public as improvements in the art; and each author, fond of his own little expedient, which by a scientific person would have been known as an easy corollary from the general theorem, has made it the principle of a practical system, thus narrowing instead of enlarging the knowledge of the art; and the practitioner, tired of the bulk of the volume, in which a single maxim is tediously spread out, and the principle on which it is founded kept out of his sight, contents himself with a remembrance of a maxim perhaps not understood, and keeps it slightly in his eye to avoid gross errors. We can appeal to the whole body of painters and draughtsmen for the truth of this assertion; and it must not be considered as an imputation of remissness or negligence on their part, but as a necessary consequence of the ignorance of the authors from whom they have taken their information. This is a strong statement, but it is not the less just. Several mathematicians of eminence have written on perspective, treating it as the subject of pure geometry, as it really is; and the performances of Dr Brooke Taylor, Gravesande, Wolf, De la Caille, and Emerson, are truly valuable, by presenting the art in all its perspicuous simplicity and universality. The works of Taylor and Emerson are more valuable, on account of the very ingenious and expeditious constructions which they have given, suited to every possible case. The merit of the former has been universally acknowledged by all the British writers on the subject, who never fail to declare that their own works are composed on the principle of Dr Brooke Taylor; but any man of science will see that these authors have either not understood them, or aimed at pleasing the public by fine cuts and uncommon cases; for, without exception, they have omitted his favourite constructions, which had gained his predilection by their universality, and attached themselves to inferior methods, or perhaps to inventions which they were pleased to regard as their own. What has been laid down in this article is not *professed* to be according to the principles of Dr Brooke Taylor, because the principles are not peculiar to him, but the necessary results of the theory itself, and inculcated by every mathematician who has taken the trouble to consider the subject. They are sufficient not only for directing the ordinary practice, but likewise for suggesting modes of construction in every case out of the common track. A person of ingenuity will have a laudable enjoyment in inventing rules for himself, and will be better pleased with such fruits of his own ingenuity, than in reading the tedious explanation of examples devised by another; and with this view we would, with Dr Taylor, "advise all our readers not to be contented with the scheme they find here; but, on every occasion, to draw new ones of their own, in all the variety of circumstances they can think of. This will take up more time at first, but they will find the vast benefit and pleasure of it by the extensive notions it will give them of the nature of the principles."

The art of perspective is necessary to those arts where there is any occasion for designing, as architecture, fortification, carving, and generally to all the mechanical arts; but it is more particularly necessary to the art of painting, in which nothing can be done without it. A figure in a picture, which is not drawn according to the rules of perspective, does not represent what is intended, but something else. Indeed, we hesitate not to say, that a picture which is faulty in this particular is as blameable as any composition in writing which is defective in point of orthography or grammar. It is generally thought very ridiculous to pretend to write a heroic poem, or a fine discourse, upon any subject, without understanding the propriety of the language in which we write; and to us it seems no less ridiculous for one to pretend to paint a good picture without understanding per-

Perspective, Aerial.

spective. Yet how many pictures are there to be seen, which are highly valuable in other respects, and yet are entirely faulty in this point? Indeed, this fault is so very general, that we cannot remember ever having seen a picture which is entirely free from it; and, what is more to be regretted, the greatest masters have been the most guilty of it. Such examples cause it to be overlooked; but the fault is not the less, but the more to be lamented, and deserves the greater care in avoiding it for the future. The great occasion of this fault is certainly the bad method which is generally used in educating persons in this art; for the young people are generally put immediately to drawing, and when they have acquired a facility in that, they are put to colouring. And these things they learn by rote, or by practice only, and are not at all instructed in any rules of art; by which means, when they come to make any designs of their own, though they are very expert at drawing and colouring every thing which offers itself to their fancy, yet for want of being instructed in the strict rules of art, they do not know how to govern their inventions with judgment, and become guilty of many gross mistakes, which prevent themselves, as well as others, from finding the satisfaction which they otherwise would do in their performances. To correct this defect, we would recommend it to masters of the art of painting to consider whether it would not be necessary to establish a better method for the education of their scholars, and to begin their instructions with the technical parts of painting, before they let them loose to follow the inventions of their own uncultivated imaginations.

The art of painting, taken in its full extent, consists of two parts; the inventive and the executive. The inventive part is common to poetry, and belongs more properly and immediately to the original design (which it conceives and disposes in the most proper and agreeable manner) than to the picture, which is only a copy of that design already formed in the imagination of the artist. The perfection of this art depends upon the thorough knowledge the artist has of all the parts of his subject; and the beauty of it consists in the happy choice and disposition which he makes of it. It is in this that the genius of the artist discovers and shows itself, whilst he indulges and humours his fancy, which here is not confined. But the executive part of painting is wholly confined and restricted to the rules of art, which cannot upon any account be dispensed with; and therefore in this the artist ought to govern himself entirely by these rules, and not to take any liberties whatsoever. For any thing that is not truly drawn according to the rules of perspective, or not truly coloured or truly shaded, does not appear to be what the artist intended, but something else. Wherefore, if at any time the artist happen to imagine that his picture would look better if he swerved a little from these rules, he may assure himself, that the fault belongs to his original design, and not to the strictness of the rules; for what is perfectly agreeable and just in the real original objects themselves, can never appear defective in a picture where these objects are accurately copied.

Therefore, to offer a short hint of the thoughts we have some time had as to the method which ought to be followed in instructing a scholar in the executive part of painting, we would first have him to learn the most common principles of practical geometry, and the elements of plain geometry and of common arithmetic. When he is sufficiently perfect in these, we would next have him to learn perspective; and when he has made considerable progress in the latter, so as to prepare his judgment with right notions of the alterations which figures must undergo, when they come to be drawn upon a flat surface, he may then be put to drawing by view, and be exercised in this alone with perspective, till he comes to be sufficiently perfect in both. Nothing should be more familiar to a painter than perspective; for it is the only thing which can make the judgment correct, and help the fancy to invent with ten times the ease that it could do without it.

We earnestly recommend to our readers the careful perusal of Dr Taylor's Treatise, as published by Colson in 1749, and Emerson's, published along with his Optics, as still the best *scientific* works on the subject. (B. B. B.)

PERSPECTIVE, Aerial, is sometimes employed as a general denomination for that which in a more restricted sense is called *aerial perspective*, or the art of giving a due diminution or degradation to the strength of light, shade, and colour, according to the different distances of objects, the quantity of light which falls upon them, and the medium through which they are seen; the *chiaro oscuro*, which consists in expressing the different degrees of light, shade, and colour of bodies, arising from their own shape, and the position of their parts with respect to the eye and neighbouring objects, by which their light or colours are affected; and *keeping*, which is the observance of a due proportion in the general light and colouring of the whole picture, so that no light or colour in one part may be too bright or too strong for another. A painter who would succeed in *aerial perspective* ought carefully to study the effects which distance, or different degrees or colours of light, have on each particular original colour, to know how its hue or strength is changed in the several circumstances which occur, and to represent it accordingly. As all objects in a picture take their measures in proportion to those which are placed in the front, so, in *aerial perspective*, the strength of light, and the brightness of the colours of objects close to the picture, must serve as a measure, with respect to which all the same colours at several distances must have a proportional degradation in like circumstances.

Bird's eye view in Perspective, is that which supposes the eye to be placed above any building, or other object, as in the air at a considerable distance from it. This is applied in drawing the representations of fortifications, when it is necessary not only to exhibit one view as seen from the ground, but also so much of the several buildings as the eye can possibly take in at one time from any situation. In order to this, we must suppose the eye to be removed to a considerable height above the ground, and to be placed, as it were, in the air, so as to look down into the building like a bird when flying. In representations of this kind, the higher the horizontal line is placed, the more of the fortification will be seen, and *vice versa*.

PERTH, the principal town of Perthshire, and the most central in Scotland, is situated on the banks of the river Tay, about twenty-five miles above its confluence with the German Ocean, in latitude 56. 23. 40. north, and longitude 3. 26. 20. west. The situation of Perth is one of the finest that can be imagined. Two beautiful and extensive meadows, called the North Inch and South Inch, bound it upon two sides. On the east it is washed by the waters of the Tay, whilst on the west and the south-west it is surrounded by a screen of hills, of moderate elevation, but richly wooded, and sloping gently down towards the town and the river. Of these hills, or rather eminences, the highest is that of Moncrieff, which is 756 feet above the level of the sea; but the landscape that opens to the eye from its summit is one of the finest in Scotland, comprehending in the northern distance a noble sweep of the Grampian Mountains, and presenting to the westward a splendid view of Strathearn, intersected by the numerous windings of its river; whilst to the east appear the Carse of Gowrie, rich in all the beauties of fertility, and the majestic Tay rolling onwards to the sea. The site of Perth is remarkably low, being only a few feet above the level of the sea; but notwithstanding this circumstance, and the vicinity of hills, the climate is not particularly moist, and is considered as healthy. The lowness of the situation, however, exposes the town to frequent inundations from the river, several of which make rather a formidable appearance in its annals. The greatest of these upon record appears to have happened in the reign of William the Lion, who is said to have narrowly escaped with his family and court, from the sudden rising of the waters. The years 1621, 1773, and 1814 are also memorable in the burgh records for similar and equally extensive casualties. The deepening of the Tay below the town, which has been in progress for some years, will, however, ultimately lessen the dangers to be apprehended from these sudden inundations, by affording a deeper and freer channel for the waters of the river.

Perth is one of the most ancient towns in Scotland, and its civil history, up to the sixteenth century, is deeply interwoven with the national annals. Its origin is buried in the obscurity of the past, and the very etymology of its name is uncertain.[1] For many centuries it was called St Johnston, which appears indeed to have been its most ancient designation. This name was, it seems, given to it from the circumstance of the first church erected in it, after the conversion of the inhabitants to Christianity, being dedicated to St John the Baptist; a circumstance which is in some degree confirmed by the ancient seal of the burgh, on which is represented the martyrdom of the saint. The city records are very ancient, but are not legible farther back than the year 1512. From that period they are very complete, and contain matter equally curious and interesting to the historian and the antiquary. Indeed, some of our early historians are of opinion that the town was founded by the Roman general Agricola, who erected a citadel to maintain his conquests, and check the wild spirit of the savage natives. In corroboration of this opinion, it may be stated, that there are no less than four great military roads, leading to the city from different points, which are all evidently of Roman origin. Its central situation, as well as the fertility of the soil, and the beauty of the surrounding country, must naturally have suggested to those discriminating invaders its occupation as a military station. But not to dwell on apocryphal events and circumstances, faintly looming on the verge of authentic history, the first fact of any importance which emerges from its early annals is the charter granted by William the Lion, in 1210, and which raised it to the dignity of a royal burgh. It has been said, however, that Perth must have been a royal burgh in 1106, from the terms of a charter granted in that year by Edgar, in favour of one John Mercer, who in it is designated as a burgess of the city. In the charter of confirmation by James VI. allusion is also made to a previous one, granted by David I., who died in the year 1153. Perth enjoys the dignity of having been the ancient metropolis of Scotland. James II. was the first Scottish monarch crowned in Edinburgh, an event which happened in the year 1447; and soon afterwards the parliament and courts of justice were removed thither; but it was not until 1482, in the reign of James III., that Edinburgh was declared to be the capital of Scotland, and the Scottish court finally removed from the city of St John.

Perth appears to have been early fortified. From its importance as the seat of government, its central situation, and its vicinity to the Highlands, some defence was absolutely necessary. In these rude ages it was surrounded by the feudal castles of several powerful barons, with some of whom the inhabitants appear to have been frequently at feud, whilst with others, as Chartres of Kinfauns, the Earl of Gowrie, the Earl of Atholl, Lord Scone, and Threipland of Fingask, they were on such friendly terms as to have had one of their number for chief magistrate. Amusing evidence is to be found in the records of the burgh, of these alternate feuds and fraternizations. The worthy burgesses seem to have been men of mettle in those days, and on various occasions sallying forth from behind their walls, set fire to the castles of their haughty neighbours, when the latter, probably in reprisal for some offence, had forbidden their vassals to carry provisions to the city. In the year 1311, Robert Bruce laid siege to the town, but was obliged to withdraw his troops, after various unsuccessful attempts to take it. Not discouraged, however, the Scottish hero, having selected a band of determined men, and chosen a dark night, led them on in person, scaled the walls, and carried the town, sword in hand, the king himself being the second man who entered the place. About the beginning of the fourteenth century, the famous combat between the Clan Chattan and the Clan Quhele or Clan Kay, took place on the North Inch, and was decided in favour of the former, partly by the bravery of a citizen or burgess called Harry Wynd, whom the chief of the Clan Chattan had engaged on the spot to supply the place of one of his men who had failed to appear. The particulars of this singular conflict have been described by Sir Walter Scott in the first series of his Tales of a Grandfather; and in his romance of the Fair Maid of Perth, he has, with equal skill and effect, availed himself of the traditional story, which he has embellished with the felicity peculiar to his rich and inventive genius. This city has also been the scene of several of those social tragedies, in which the history of Scotland, in those rude times, was so prolific. In the year 1336, King Edward III. of England stabbed his brother the Duke of Cornwall, before the high altar of the church of St John; and in 1437, James I. was murdered in the monastery of the Blackfriars, with circumstances of the most savage barbarity. The murderers were executed in Perth, and the details of their punishment are of the most revolting character, reflecting but little honour on the good feeling and humanity of our forefathers. Perth appears to have been several times visited by the plague, particularly in 1512, 1585, 1608, and 1645. Its ravages during the last of these visitations were severe, three thousand persons having become its victims. In 1617, James VI. honoured the ancient capital of Scotland with a visit, the details of which, as found in the burgh records, are not a little graphic and entertaining. And in 1623, one of those exhibitions, of which James was so fond, and which leave a stain upon the national annals, took place in Perth; we mean, the burning of three poor women for witchcraft. In 1633, Charles I., in his tour through Scotland, visited Perth; and in 1651, Oliver Cromwell took military possession of the city, and erected a citadel on the South Inch. In 1559 John Knox appeared in Perth, and the excitement produced by his preaching, with the imprudent conduct of the Catholic clergy, caused the destruction of the finest ecclesiastical buildings in the city. Previously to the Reformation, Perth was crowded with religious houses, the cowled inmates of which swarmed in the city like bees. Many of these houses were buildings distinguished for elegance and taste, and the destruction of them is therefore much to be regretted. But the fury of the inhabitants was, in a great measure, confined to the edifices, which they were taught by their new instructors to regard as the abodes of iniquity; and hence, whilst they pulled down "the nests that the rooks might be scattered," they offered little personal insult to any one, and not a single Roman Catholic was put to death. The men of Perth, however, were zealously devoted to the cause of the Reformation. Three hundred of their number, bedecked with "St Johnston ribands," set out from the city, determined to prosecute the work of reformation, or to perish in the attempt. Before they reached Stirling, their numbers had increased to five thousand; and by the appearance of this faithful band, the struggle between the queen and the reformers was speedily brought to an end without the effusion of blood. The year 1600 was rendered memorable by the occurrence of the famous Gowrie conspiracy, as it is called; one of those events on which ingenuity and research have exhausted themselves in vain, and which, in its origin and circumstances, still remains enveloped in impenetrable mystery.

---

[1] Lord Hailes informs us, in his Annals, that he had been favoured with various etymologies of the name, but not knowing which to choose, he had omitted them all. We learn from Fordun, however, that the town was formerly called *Bertha*, which is probably the Celtic *Bhar-tatha*, signifying the height of Tay, or Kinnoull Hill, immediately contiguous to the town; and this conjecture is strengthened by the circumstance that the word *Tatha* in Celtic is pronounced as *Ta* or *Tay* in English; so that *Bertha* is very nearly the exact sound of *Bhar-tatha*. But as the mutes B and P are interchangeable in Celtic, the one being used indiscriminately for the other, *Bertha* was shortened into *Berth* or *Perth*, in the ordinary course of human speech. It may be added, that the names of many places in the neighbourhood, as well as all over Scotland, are of Celtic origin, and that the vernacular language of the people not many miles from Perth still continues to be a dialect of that original language.

The present level of the city has been ascertained to be higher than it was at one period, and the level of the river appears also to have risen along with it, to the great injury of the navigation; vessels of considerable burden formerly discharging their cargoes farther up than they can do at present. The burgh of Perth is invested with an ample jurisdiction over the river, but does not appear to have paid much attention to the improvement of the navigation. Of late years, however, the subject has excited considerable interest; and, in 1834, the town-council obtained an act for deepening the river, and constructing a tide harbour and wet-dock. A powerful steam dredging-vessel has for some time been in operation on the river, and such have been its effects, that vessels of 200 tons, it is expected, will be soon able to discharge their cargoes at Perth. The city has also lately obtained the privilege of bonded warehouses, which will materially assist its foreign trade. The exports of the city, however, are comparatively but trifling; the accessible and thriving port of Dundee absorbing a great part of the foreign as well as coasting trade, which Perth formerly possessed. Potatoes constitute a considerable article of export to the London market, and the external commerce of the city may now be expected to improve, as the facilities of its river navigation increase. The imports are chiefly from the Baltic, and consist of flax, hemp, timber, seeds, cheese, and foreign spirits; coals, lime, salt, and manure, form the general coasting freights. In 1836, 736 vessels entered the harbour of Perth, the tonnage of which amounted to 40,000 tons. The capital vested in shipping is, however, but trifling. Between five and six thousand tons, in about eighty vessels of every description, comprise the shipping of the port of Perth. The salmon caught in the river form an item of some importance in its commerce, and are exported to London. The revenue of the burgh from its fisheries alone amounts to L.830 per annum.

A considerable quantity of cotton goods is manufactured in Perth, chiefly for Glasgow houses. The principal articles are ginghams, pullicates, umbrella-cloths, harness-muslins, and linen-lawns, employing about 1600 weavers. Calico printing and bleaching are carried on in the neighbourhood, to a very considerable extent. A large mill has lately been erected for spinning flax; and an establishment of this description has long been known as one of the best managed and most extensive in Scotland. There are, besides, three large founderies in operation, in which the manufacture of machinery and iron goods is considerable. But Perth appears to have rather retrograded as a seat of trade and commerce, as the early records of the burgh show that it formerly carried on an extensive traffic with the Baltic, the Mediterranean, and the Netherlands; the decay of which arose most probably from the increasing obstructions to the navigation of the river, by the gradual elevation of its bed from the accumulation of alluvial deposit, and from other incidental causes. The tanning of leather and the manufacture of gloves were at one time extensively carried on in Perth, but these trades have now greatly fallen off. About forty years ago, the printing of books was also a trade of some importance, but it is now of little consequence. Of late years ship-building has also been carried on to some extent. From the eligibility of its situation, the cheapness of living, and the low price of education of the best description, many respectable families in easy circumstances make Perth their residence.

The government of the city is vested in a lord provost, who is also sheriff and coroner, four bailies, a treasurer, the dean of guild, who is *ex officio* a member of the council, and nineteen councillors. There are two city clerks, a procurator fiscal, and a chamberlain. The city sends a member to parliament; and, in 1837, the constituency amounted to 1073. The burgh has a very large property and revenue, the former derived chiefly from the favour and munificence of several of the Scottish sovereigns. The property is estimated at L.67,510. 11s. 10d. and the revenue for 1836–1837 was L.6334. 8s. The debt of the city amounts to L.33,723, and the expenditure to L.5926. 11s. 7d. After Edinburgh was constituted the capital of the kingdom, Perth stood second on the roll of burghs of the Scottish parliament, and is still entitled to hold that rank. Its chief magistrate has for centuries enjoyed the title of lord provost; and by a judgment of the Court of Session (12th March 1836), he is still entitled to that distinction. The Circuit Court of Justiciary is held here twice a year, when the criminal offences committed in the counties of Perth, Fife, and Forfar are tried. At the spring court of 1838 the cases brought to trial were upwards of fifty in number, and although few of them were of great turpitude, the court were occupied during five days in disposing of them.

In the year 1831 the population of Perth amounted to 20,016 persons, but by a census recently taken, it is at present only 19,601, being 415 less than it was in 1831. The causes of this decrease are not easily ascertainable. Of the population, 11,683 have been stated as connected with the established church, and the rest are dissenters. In 1831 there were 2049 inhabited houses, containing 4956 families. Of public buildings, the principal are the bridge over the Tay, the barracks, the dépôt built for the reception of French prisoners during the war, St Paul's Church, the building erected to the memory of Provost Marshall, which contains a public library and the museum of the Literary and Antiquarian Society, the Perth Academy, the water-works, and the county buildings, a large and tasteful structure, situated close to the bank of the river. The lunatic asylum, an elegant building, is situated on the hill of Kinnoull; and an infirmary is almost finished. Besides these public buildings, several handsome streets have of late years been erected, which, combined with the natural beauty of the situation, render Perth one of the most desirable places of residence in this country. The town is well supplied with water, filtered from the river by a very ingenious method; and it is also well lighted with gas, by a company established for the purpose. The assessment for water cannot exceed five per cent. on the rental. The revenue of the post-office is about L.4000.

The Perth Academy, instituted in the year 1760, enjoys a high reputation as a seminary of classical and scientific learning. There are thirty-five schools in Perth, including the Academy. In the year 1834 the town-council applied to government for a grant, which, assisted by private subscriptions, has provided accommodation for 400 additional scholars. In 1697 a proposal was made to remove the University of St Andrews to Perth. The inhabitants have established several religious and charitable societies; and also a literary and antiquarian society of some note, which has a museum and library attached to it. A savings-bank was likewise established in 1815, the accumulated deposits of which, from that time till 1836, amounted to L.3188. 13s. 10d., whilst the sum lodged during 1836 exceeded L.381. In 1836 the assessment for the poor was L.2128. 13s. 3d. which was raised by a five per cent. tax upon rental, and L.723. 5s. 2½d. were collected at the church doors; besides which, the incorporated trades expend annually above L.2000 for the relief of their poor members. The poor's-funds obtained from the hospital of King James average yearly about L.435; and there are two other mortifications for their behoof, which realise annually L.312. 10s.; so that, not to mention various charitable societies, the interests of the poor are apparently well attended to in this ancient city.

PERTHSHIRE, one of the most extensive and beautiful counties in Scotland, being very compact and almost circular in form, is situated nearly in the centre of the kingdom. Its extreme length from east to west is about seventy-seven miles, and its greatest breadth from north to south is about sixty-eight miles. Its area has been variously estimated; but the nearest approximation to accuracy gives 2588 square miles of land and more than fifty of water. Of the 1,656,320 acres forming its superficial contents, from 500,000 to 600,000 are, according to the most recent statements, under cultivation; as many more are still uncultivated, though capable in part of tillage; and the remainder is almost wholly barren and unproductive. On the east Perthshire is bounded by the counties of Forfar, Fife, and Kinross; on the north, by Inverness and Aberdeen; on the south, by Stirling and Clackmannan; and on the west, by the shires of Argyle and Dumbarton. Its ancient and still popularly known divisions are Monteith, Athole, Strathearn, Breadalbane, Rannoch, Stormont, Perth proper, and Gowrie, to which some add Balquhidder and Glenorchy. It is under the jurisdiction of a sheriff and two substitutes, one of whom resides at Perth, and the other at Dumblane. There are within its boundaries seventy-eight parishes, or portions of parishes, some of them running into other adjacent counties.

Perthshire is distinguished amongst the counties of Scotland for the rich, varied, and picturesque beauty of its surface. From the commanding range of the Grampians, and numerous other secondary elevations, the country slopes gently down into extensive tracts of rich and fertile land, beautifully diversified, and adorned with wood and water, hill and dale, in every possible combination. Where the elevated ranges gradually disappear in the champaign country, nothing can exceed the rich and undulating character of the scenery, broken into noble and irregular valleys, or spreading out into extensive alluvial tracts, watered by streams of almost every size and character. The county of Perth is now generally divided into the highland and lowland divisions, the surface of the former being far more extensive than that of the latter. The fertile or lowland districts are chiefly, but by no means entirely, situated towards the eastern and the southern boundaries of the county. The fine valley of Strathearn, having the Grampian range on the north-west, with the Ochils and Sidlaw hills on the east, traverses it from north-east to south-west, and, including certain portions of the contiguous valleys of the Tay and the Almond, forms one of the richest and most extensive tracts in the kingdom. Besides the extensive valley of Strathearn, there are others of considerable dimensions, studded with lakes, and enlivened with streams of every variety of character. Such are those of the Tay, the Isla, and the Almond, and the valley of the Tummel, with its clear, soft, and beautiful lake, richly fringed on the margin with wood of various kinds, rising boldly up on the south, into the steep ridges of Schehallion and Faragon. Glenlyon and the valley of the Brann are not less rich and beautiful; and there are many others scarcely inferior to these in size and picturesque variety of scenery.

Perthshire is distinguished for its noble ranges of mountains, as well as for the great elevation to which some of them attain. The highest is Benlawers, 4015 feet: Benmore is 3903; Cairn Gower, 3690; and Schehallion, 3564. This last mountain is distinguished by its fine conoidal outline, as well as for being the spot selected by Dr Maskelyne for making his experiments to determine the density of the earth. Benledi rises to the height of 3550 feet; Ben Ardlanach to that of 3500; and Ben Venu to that of 3000; besides many others of considerable though inferior altitude. The principal lake is Loch Tay, fifteen miles in length, and about two at its greatest breadth. The outline of this fine lake is somewhat deficient in beauty, from the nearly straight and rigid character of its shores, particularly on the north side. At Killin and Taymouth, however, the scenery is varied and noble, presenting ample materials to the pencil of the artist. Loch Ericht is about sixteen miles in length, but half of it is included in the county of Inverness. The country around it is bare, wild, and devoid of interest. Loch Rannoch, which is nearly twelve miles in length from east to west, exhibits greater variety of outline, and its banks are agreeably diversified with old birches, the remnants of the once extensive forest of Rannoch. The finest view of Schehallion is obtained from the northern bank of this lake, at a point about four miles above Kinloch Rannoch. Viewed from the spot in question, the mountain presents a figure nearly conical, appearing to rise out of the lower extremity of the loch, and showing, in contrast with the water, one of the most magnificent natural objects to be seen in this or in any other country. Loch Earn, about six or seven miles in length, is a beautiful lake, with a richly-wooded, and in many places a highly-cultivated, but narrow strip of margin, from which the hills ascend rapidly and steeply. On the south-west there is the noble chain of lakes, Loch Ketterin, Loch Achray, and Loch Vennachar, which discharge their waters into the Forth. The scenery of these lakes is so well known as the locality of Sir Walter Scott's poetical romance, the Lady of the Lake, that it is unnecessary to describe its peculiar features. They are of the most varied and striking kind, such indeed as require to be seen in order to be fully appreciated; and the pencil rather than the pen must be employed to convey to those who have not beheld them a just conception of their mingled beauty, wildness, and magnificence. Divided from these by a ridge of elevated hills, we find Loch Ard, Upper and Lower, and Loch Con, from which the Forth takes his rise. The well-known lake of Monteith is in the vicinity of the latter. There are many other lakes, such as Loch Tummel, Loch Garry, Loch Voil, and Loch Lubnaig, all of some extent, and some of them rich in picturesque beauty of situation and outline. In the eastern quarter of the county is to be found another chain of lakes extending from near Dunkeld towards Blairgowrie, which are less known than they deserve to be. These are the three lochs of the Lowes, Marly, and Clunie. An old mansion on the loch of Clunie is said to have been the birthplace of the admirable Crichton.

The rivers of Perthshire are, the Tay, the largest stream in Scotland, with a course about ninety miles in length; the Isla, with its tributary the Ericht; and the Earn. The Tay and the Earn belong exclusively to this county, their entire course being confined to it; the Isla in the early part of its course sweeps through the western part of Forfarshire. The Tay is considered to discharge more water into the sea than any other river in Great Britain; the basin which it drains not only being very extensive in itself, and the seat of elevated mountain ranges, but abounding in streams of considerable magnitude, the principal of which it absorbs in its progress towards the German Ocean. Of those minor streams, which augment the volume of the Tay, the chief are the Lyon, the Almond, the Isla, the Brann, the Garry, and the Tummel. Throughout a considerable part of its course the scenery on the banks of the Tay is of the grandest and most impressive character; particularly in the upper part of its course, from Loch Tay, through the strath which takes its name from the river, to the pass of Birnam, where its banks become more level, and the country around assumes a softer character. But what is lost in boldness and grandeur is fully compensated by the rich and varied beauties of a wooded and cultivated soil, enriched with noble seats and stately mansions. The Earn passes through a rich and picturesque country; in some places bold and alpine in its character, and in others abounding in the mellow beauties of cultivation. On its banks, not far from its confluence with the Frith of Tay, stands the village of Pitcaithley, celebrated for its mineral waters, and now a favourite resort of fashionable valetudinarians. The Tummel is one of the finest rivers in Scotland, and is especially rich in wild and romantic scenery, from its source in Loch Rannoch, to its confluence with the Tay, immediately below the village of Logierait. The Earn and the Lyon, the Almond, the Brann, and the Airdle, besides other smaller streams, we can only afford to notice generally. They all partake more or less of the character of the fine districts which they traverse; imparting life and animation to many a mountain solitude, besides draining and watering extensive tracts of country.

Of the temperature of a region differing so much in exposure and elevation, nothing certain can safely be affirmed. In the upper and more elevated districts, where the mountain ranges slope down into the level country, and amongst the numerous glens which penetrate these in all directions, the climate is charged with moisture in a higher degree, the winters are longer and more severe, the snow frequently lies longer on the ground, and the spring is generally later than in the lower districts of the county. The highest summer temperature rarely exceeds sixty-five degrees, and the mean temperature, in three different situations in the county (none of them, however, more than 150 feet above the sea), has been found to be forty-seven degrees. The cloudy character of the atmosphere in the mountainous districts, by excluding the light of the sun, retards the ripening of the crops, and accumulates moisture, which tends to lower the average temperature. The district of Perth proper is said to be the least humid, the average water being only twenty-three inches; but in the Carse of Gowrie, on the shores of the Frith of Tay, the mean quantity of rain for twelve years was twenty-four inches and a half; at Perth, for a period of sixteen years, it was 26·95 inches; and at Belmont, in Strathmore, for thirty years, it was as high as 30·40 inches. The extensive drainage, executed of late years by various proprietors, has no doubt tended considerably to ameliorate the climate.

As far as is yet known, the minerals of Perthshire, in a commercial or economical point of view, are of no great public importance. Abundance of coal is to be found at Culross on the Forth, where it has long been wrought; but the situation renders it of no use to the inland and higher districts. Limestone is plentiful, and is wrought in considerable quantities; but for want of proper fuel it is not so generally used as it would be, peat, the only fuel in the upper districts, not being strong enough for the purpose of calcination. Lord Willoughby d'Eresby and Sir Niel Menzies have, however, lately devoted their attention to the compression of peat; and the results which they have obtained encourage the hope that that species of fuel may yet be rendered available to the improvement of the barren districts in which it abounds. Marble of a pretty good quality is found in Glentilt, and is now becoming an article of some importance in commerce. Slate is wrought in various places, particularly in the neighbourhood of Dunkeld; ironstone is found on the Devon, where it supplies the extensive iron-works established there; and copper and lead mines are said to have been at one time in operation, but have long since been abandoned. On the east side of the county shell-marl is plentiful, and is freely used as a manure. In the higher districts the general basis is granite, but in the lower sandstone prevails. The sandstone, which is of the primitive kind, stretches from the valley of Strathmore to the neighbourhood of Callander, with a dip varying from 15° to 25° towards the north-west. It seems to have received this position from the action of the central force which elevated the range of trap hills traversing the island from Montrose to Dumbarton.

In a county of so great extent, and possessing such a variety of surface, considerable diversity must exist in the character of the soil. The carse or alluvial lands on the shores of the Frith of Tay have long been celebrated for their fertility. They are considered as the joint produce of river and sea deposition for a series of ages. The general character of the soil is that of a rich clay, very deep, in some places alternating with layers of peat, and having sand and marine deposits at the bottom. This soil is not wholly alluvial, being sometimes mixed with the debris of trap-rocks, and also of the sandstone, which, as already mentioned, forms a geological characteristic of the lowland districts of Perthshire. Considerable tracts of this inferior description of alluvial soil are found accompanying the courses of the principal rivers, and extend into the upper portions of Strath-Tay, Strath-Airdle, and Strath-Tummel. A soil composed of clay and sand, and called by agriculturists a *till*, extends along a vast tract of this county from east to west, and is supposed to be formed from the red sandstone prevalent in that district. Peat is to be met with almost everywhere in Perthshire; that known by the name of *Moss Flanders* is said to extend over ten thousand acres, and is amongst the largest continuous tracts of this description in the united kingdom.

In the arable districts of this county, such as the Carse of Gowrie, and the fertile lands skirting part of the course of its principal rivers, the modes of agriculture and management of farms are much the same as in the other agricultural counties of Scotland. But of late years a spirit of improvement has been introduced, which has been much felt in this county, chiefly in the upper districts, where the old "runrig" system long kept its ground tenaciously, under the modified form of joint farms. The arable farms vary in extent from fifty to five hundred acres, and upwards; and in the Carse of Gowrie the rents are as high as in any part of the kingdom. Wheat is raised on the best soils, and has been attempted, not unsuccessfully, as high up in the county as Dunkeld. In the wheat-growing soils this crop usually alternates with beans and peas, barley, hay, and oats. Flax is more extensively raised in Perthshire than in any other part of Scotland, arising most probably from its being the raw material of the indigenous manufacture of the county. Potatoes and turnips are extensively cultivated, and of late years on the most improved methods. The pasture-farms in the higher parts of the county are large, and raise great numbers of sheep, chiefly of the black-faced kind. Other descriptions of live stock are not so much cultivated. Dairy farming does not form a prominent feature in the rural economy of this county. In some favoured spots orchards succeed well, many of them are very large, and their produce is highly celebrated. Perthshire is remarkable for the great extent and beauty of its woods. Of these, many are of natural wood, chiefly oak. But extensive plantations of various kinds of trees have been made during the last fifty years by several proprietors, especially by the late Duke of Atholl, whose planting operations have been carried on upon the most extensive scale, at once beautifying and enriching one of the finest parts of the county. To him Perthshire is indebted for the introduction of the larch, which has been found singularly adapted to the climate and soil. The plantations of this tree have thriven amazingly, and are of great extent and value. Larch has been used in ship-building, instead of oak; but their relative value for such a purpose is not yet fully ascertained. In 1674 the valued rental of Perthshire was L.339,892 Scots; and in 1815 the annual value of assessed property amounted to L.555,552 sterling.

This county is particularly rich in splendid seats and mansions belonging to the great proprietors. Of these, the most remarkable are Dunira, Taymouth Castle, Dunkeld House, the Palace of Scone, Kinfauns Castle, Murthly House, Dupplin Castle, and Blair Castle. Castle Huntly and Blair Castle are fine specimens of the old baronial and castellated habitations of the ancient lords of the soil; and Doune Castle is considered as one of the finest ruins of its kind in Scotland. Perthshire is not remarkable for antiquities, secular or ecclesiastical. Druidical circles and Roman remains are found in various places. Of the former, one circle almost entire, called by the country people Standing Stanes, formerly existed at Craigmakerran, the property, we believe, of the guildry of Perth; but about twenty-five years ago it was barbarously destroyed, and the stones blasted for the purpose of being employed in the erection of a farm-steading. Before this act of Vandalism was committed, the circle in question, which stood on a projecting crag, about six miles from Perth, on the Isla road, was perhaps one of the most perfect of the kind in the kingdom. Of the latter, the camp or station at Ardoch, and that at Comrie, are well known, as well as the Roman road, which seems to have connected them. There is another at Delvin, which is scarcely less remarkable. The ruins of the cathedrals of Dunblane and Dunkeld are also in excellent preservation, though the architecture is by no means of the highest order. The tower of Abernethy, which has long puzzled the heads of antiquaries, is unfortunately decaying rapidly, as is also the fine old abbey of Culross.

Red deer are still numerous in Perthshire, and impart a feature of peculiar interest to its forest scenery. The deer-forest of Athole is said to contain 80,000 acres; and the number of the deer in the whole county is estimated at 6000, of which about 100 are annually killed. Harts are destroyed in the months of August and September, and hinds in January, the last month of the season. From several of the large proprietors having combined to preserve the deer, it is considered that their number must be greatly upon the increase. Feathered game of every description abounds in the upland district of Perthshire, and affords a rich treat to the sportsman. Many of the moors are let to sportsmen, and bring large sums annually. Salmon is amazingly plentiful, especially in the Tay, and is also found in the tributaries of that river. The fisheries on the Tay alone are understood to bring a rental of L.10,000 a year, and those on the Earn are likewise said to be productive. The export of salmon forms a considerable article of commerce, as is mentioned in the account of Perth.

The principal towns are Perth and Culross, which are royal burghs; Crieff, Callander, Kincardine, Doune, Comrie, Dunblane, Auchterarder, Dunkeld, and Blairgowrie. Of the latter class, the largest is Crieff, the population of which in 1831 amounted to nearly 5000. It is a chief seat of the linen manufacture, which is also the principal occupation of Blairgowrie and Auchterarder, with a population of about 3000 each. None of the other towns is very remarkable, if we except Comrie, which is celebrated for the frequency of earthquakes in its neighbourhood; Dunblane, for its mineral waters; and Doune, once a great Highland mart, for its manufactory of pistols. The villages are numerous, and many of them populous and thriving; but it is unnecessary to particularize them. The greater part of Coupar Angus is included in the county of Perth.

The manufacture of linen, as already mentioned, is the staple manufacture of Perthshire; but cotton goods are also produced to a considerable extent. Mills for spinning flax, bleachfields, and calico-printfields, are numerous; and there are some large establishments for spinning cotton-yarn at Stanley near Perth, and at Danston. Paper is likewise manufactured to a considerable extent; and oil-mills are to be found in various places. A great many shoes are made in Perth, and the tanning of leather is carried on to a considerable extent at Crieff and at Thornhill. Of agricultural produce, large quantities of sheep and black cattle from the upper districts are brought to the country markets and sold there. Wool is likewise an article of considerable sale. From the more fertile districts large quantities of grain are annually brought to market. Bark and timber, principally larch and oak, also form commercial articles of no small importance. The produce of its fisheries has already been noticed as being amongst the list of exports. Limestone, slate, freestone, marl, and marble, from the fine quarries of Glentilt, are also brought to market, although, from the difficulty of transport, to a much less extent than they would otherwise be done.

In a word, the leading characteristics of this noble county are the variety and diversity of its scenery and productions, and the picturesque manner in which these are frequently grouped together. Fertility and barrenness, the wildest alpine magnificence, and the most delicious scenes upon which the eye of the lover of natural beauty could desire to rest; the rugged mountain towering in rude majesty, and the sweet glen enlivened with sunshine or curtained with mist; the rich alluvial plains of England contrasting with the glories of Switzerland in a more softened and subdued form; these are the general and prominent features by which it is distinguished. To the tourist it presents attractions of almost every kind. It is a sort of shifting diorama, in which new scenes remarkable for new beauties continually present themselves to his view, leaving upon his mind the impression that the last is, in some respects, the finest he has yet beheld. To the sportsman it opens a boundless field of amusement in its beautiful streams and its extensive moors, where the grouse, undeterred by the deadly hostility of man, renew their race but only to invite renewed destruction. In this county the naturalist has still much to explore; and after all the labours of Lord Webb Seymour, Professor Playfair, and some others, Glentilt alone would occupy a generation of mineralogists and geologists. In a word, this county, rich in every kind of natural beauty, and possessing many localities which have a deep historical interest attached to them, is not undeserving of the preeminence which has, by universal consent, been assigned to it, and merits a far larger share of attention than in the present article we have been able to bestow upon it.

The population of the county of Perth, in 1831, amounted to 142,894 persons, being an increase since 1821 of only 3844. The number of families was 31,749, and that of inhabited houses 23,809. Of the relative numbers employed in trade and agriculture we have no recent returns. The county sends a member to parliament, as does also Perth, the principal city. Culross, Queensferry, Dunfermline, Inverkeithing, and Stirling, unite in returning a third. The only change affecting this county made by the reform act, was enfranchising the city of Perth, which previously had only a fraction of a representative.

PERTINAX, an illustrious Roman emperor, who succeeded the detested Commodus. He was descended of a mean family, and, like his father, who was either a slave or the son of a manumitted slave, he for some time followed the humble employment of drying wood and making charcoal. His poverty did not, however, prevent him from receiving a liberal education. For some time he was employed in teaching a number of pupils the Greek and the Roman languages in Etruria. But having left this laborious profession, he became a soldier, and by his valour and intrepidity gradually rose to offices of the highest trust in the army, and for his services was made consul by M. Aurelius. He was afterwards entrusted with the government of Mœsia, and at length presided over the city of Rome as governor. When Commodus was murdered, Pertinax was universally chosen to succeed him in the imperial dignity; and his refusal, on the plea of old age and increasing infirmities, did not prevent his being saluted emperor and Augustus. He complied with reluctance; but his mildness, his economy, and his popularity, convinced the senate and the people of the prudence and the justice of their choice. He forbade his name to be inscribed on such places or estates as formed part of the imperial domains, and asserted that they belonged not to him but to the public. He melted all the silver statues which had been raised to his predecessor, and exposed to sale his concubines, horses, arms, and all the instruments of his pleasure and extravagance. With the money raised from these sources he enriched the empire, and was enabled to abolish all the taxes which Commodus had laid on the rivers, ports, and highways, throughout the empire. These patriotic actions gained him the affection of the worthiest and most discerning of his subjects; but the extravagant, luxurious, and vicious, raised a loud clamour against him; and when the emperor attempted to introduce amongst the prætorian guards such discipline as was absolutely necessary to preserve the peace and tranquillity of Rome, the flames of rebellion were kindled, and the minds of the soldiers completely alienated. Pertinax was apprized of their mutiny, but refused to fly at the hour of danger. Disregarding the advice of such of his friends as wished him to withdraw from the impending storm, he unexpectedly appeared before the seditious troops, and, without fear or concern, boldly asked them whether they who were bound by duty to defend the person of their prince and emperor, were come to betray him and to shed his blood? His undaunted courage and intrepidity would have had the desired effect, and the soldiers had begun to retire, when one of the most seditious of them advanced, and darted his javelin at the emperor's breast, exclaiming, "The soldiers send you this." The rest instantly followed the example; and Pertinax, muffling up his head, and calling upon Jupiter to avenge his death, remained unmoved, and was immediately despatched. His head was cut off and carried in triumph to the camp upon the point of a spear. This abominable murder happened in the 103d year of the Christian era.

It was no sooner known that Pertinax had been murdered, than the enraged populace flocked from all quarters of the city, and, uttering dreadful menaces against the authors of his death, ran up and down the streets in quest of them. The senators were no less concerned for his death than the people, probably because they were now convinced that the soldiers would suffer none but tyrants to reign. However, as they had more to lose than the common people, they did not offer to revenge his death, but either shut themselves up in their own houses, or in those of the soldiers of their acquaintance. Such was the unfortunate and lamented end of Publius Helvius Pertinax, after he had lived sixty-six years, seven months, and twenty-six or twenty-eight days; and reigned, according to Dio Cassius, eighty-seven days, that is, from the 1st of January to the 28th of March. His body, together with his head, was interred with great pomp by Didius Julianus, his successor, in the burying-place of his wife's family. Septimius Severus, with the title of emperor, assumed the name of Pertinax, which he knew would, above any thing else, recommend him to the army in Illyricum, and to the Roman people. He punished with great severity all those who had been accessory to his death; disbanded the prætorian guards; honoured his memory with a most magnificent funeral, at which was carried the effigies of the deceased prince; pronounced his panegyric, and caused him to be ranked in the number of the gods, appointing the son chief priest to his father. The day of his accession to the empire was yearly celebrated with the Circensian games, and his birth-day, for many years afterwards, with other sports. He performed great things, says Herodian, during his short administration, and would have restored the empire to its former lustre, had he been indulged with a longer reign.

PERTUIS, a city of France, in the department of Vaucluse, and arrondissement of Apt. It is situated on the river Air, about three miles from its junction with the Durance, and contains about 540 houses, with 4280 inhabitants, who are chiefly employed in spinning and weaving silk, and in the distillation of brandy. Long. 5. 30. E. Lat. 43. 44. N.

PERU.

Peru is the name of one of the republics of South America, but it likewise designates a large empire long since dismembered, yet still renowned for its wealth and ancient civilization. The limits of the present state do not comprehend much more than one third of the country over which the incas held dominion, from its having been repeatedly partitioned by the Spaniards, and always unwisely even for themselves. Ancient Peru extended from about 2. 0. of north to the twenty-sixth parallel of south latitude, thus including what is now called the Republic of the Equator, or Quito; and from 57. 0. to 81. 0. of west longitude, thus comprehending the whole of Bolivia or Upper Peru. Previously, however, to defining the boundaries of the republic, and describing its present condition, we shall briefly glance at the early annals of the country, and then take a rapid historical survey of the political revolutions which it has undergone, from the period when the Spaniards first drew their swords upon the "Children of the Sun."

The native annals of Peru ascend no higher than the era of the first inca, who flourished in the twelfth century. The individual who first established monarchical authority in the country was called Manco Capac, supposed by the natives to have been commissioned by divine Providence to deliver the world from an evil genius, to whose diabolical sway it had been abandoned. From this superstition, and also from tradition, it appears that previously to the period in question, the inhabitants of Peru ranked amongst the most barbarous of the American savages, roaming the primeval forests with which their country was then covered, more like wild beasts than men, strangers to agriculture and to all the useful arts, and having no fixed place of abode. Manco Capac, however, along with the beautiful Mama Oello or Ocollo, at once his wife and sister, reclaimed the Peruvians from this degraded condition. He showed them how to till and irrigate the soil, to construct residences, and to fix the division of lands. He overthrew their altars which were stained with blood, and taught them the more harmless idolatry of worshipping the sun. Assisted by Oello, he instructed the people in the moralities of life and the obligations of nature; he enjoined every man to bestow a portion of his time and industry for the benefit of his neighbour, and inculcated brotherly love not only amongst members of the same, but of different families. He framed laws for the happiness of the community, and commanded obedience to them more by humanity than by force. At the same time he compelled his subjects to submit implicitly to the will of the incas, and retarded the progress of the human mind by making it unlawful for a son to follow any profession except that of his father. The empire which this remarkable person founded comprised only a small territory around the city of Cuzco; and the Peruvian traditions assign no earlier date than that of his reign to the dawn of civilization. It is the opinion of Humboldt, however, that the architectural monuments which are found on the elevated table-land of Tiahuanaco, had an origin prior to the twelfth century, and that they served as models for the edifices which the incas erected at Cuzco; thus proving, that remarkable advancement had been made in the useful arts before the time of Manco. Who the architects of these original structures really were, it is nearly impossible to conjecture, far less to assert with confidence. The Spaniards, on their arrival in the country, were informed by the natives that they were constructed by "a race of white and bearded men," who inhabited the ridge of the Cordilleras long before the foundation of the empire of the incas.

But to whatever race they may have belonged, it seems perfectly certain that they had found their way to Peru along the ridges of the Cordilleras, and that the civilization of South America, as well as that of Mexico, emanated from the north. The following observations of Humboldt, in reference to the appearance of Manco Capac, are characterized by his usual sagacity. "Though no traditions point out any direct connection between the nations of North and South America, their history is not the less fraught with analogies in the political and religious revolutions from which dates the civilization of the Aztecs, the Muyscas, and the Peruvians. Men with beards, and of fairer complexions than the natives of Anahuac, Cundinamara, and the elevated plain of Cuzco, make their appearance without any indication of the place of their birth, bearing the titles of high priests, legislators, the friends of peace and the arts, and operate a sudden change in the policy of the nations, who hail their arrival with veneration. Quetzalcoatl, Bochica, and Manco Capac, are the sacred names of these mysterious beings." Still this only refers to a second migration. Those to whom the natives attributed the construction of the more ancient works had arrived in the country long before the first inca came amongst them, no one knew from whence. But over the erection of these earliest architectural monuments there hangs a veil of impenetrable mystery.[1]

Under the sway of Manco and his successors the improvement of the barbarians of Peru advanced with amazing celerity; but it soon reached as high a point as the state of knowledge and the political circumstances of the country would admit. In Peru agriculture was carried on with greater skill than in any other part of America; and the monarchs themselves set an example of industry, by cultivating a field near Cuzco with their own hands; an honour which is still conferred upon agriculture in the "celestial empire." They showed much ingenuity in the building and navigation of their floats; but it was in the erection and ornamenting of their temples and palaces that the Peruvians displayed the utmost extent of their constructive skill. The ruins of these magnificent edifices, which are found in every province, attest at once the great power possessed by the early monarchs, and the high degree of knowledge in the arts to which the people had attained; whilst they also show that during two centuries at least the nation must have subsisted in a state of considerable improvement. The great temple of the sun at Pachacamac, with the palace of the inca, and the fortress, were so connected together as to form one great building half a league in circuit. But perhaps the noblest works of the incas were the two great roads from Cuzco to Quito, a distance of not less than 1500 miles. One of these was carried through the mountainous country, and the other wound along the maritime plains. At proper intervals storehouses were erected for the accommodation of the inca and his attendants in his progress through his dominions; and flying bridges of ropes were stretched across the torrents which intersected the road in their course from the Andes to the western ocean. Although these roads were only fifteen feet in breadth, and not fit for carriages, yet they must be considered very wonderful works, from the natural obstacles which had been overcome in constructing them. Mounds of earth and other works rendered the ascent of hills comparatively easy. Granaries were built at certain distances; and charitable houses, ever open to the wanderer, were founded by the incas. Canals, fortresses, and other buildings of a public nature, varied and improved the aspect of the country.

In many of the provinces, the sides of lofty hills, or rather mountains, are cased round with terraces or hanging gardens, which rise one above another to a surprising elevation. Each terrace is faced with stone, and although of inconsiderable width, they cover the sides of such high and extensive mountains, that they alone must have produced subsistence for a large population. These terraced strips of land were by the Peruvians called Andenes, which probably induced the conquerors to give the name of Andes to the whole of the gigantic mountain chain which stretches from the Straits of Magelhaens to the Isthmus of Panama. The Andenes are often to be seen in districts where rain never falls, and how they could have been irrigated is now unknown.[2] Amongst the remarkable works of the ancient Peruvians were the azequias or aqueducts, by which large tracts of country now condemned to perpetual sterility were made fertile by water conveyed from an immense distance. The subterraneous azequias of Nasca were of great extent; and although many of them are choked up, a sufficient number remain to give amazing fertility to the valley of Nasco. It is not known how far they penetrated, but it is supposed that the Peruvians drove an adit horizontally until they met with a perennial spring.

The skill of the ancient Peruvians in mining, metallurgy, and the working of the precious metals, was considerable, and beyond that of the other American nations. Not only were the sacred temples and the royal residences profusely adorned with ornaments of gold and silver, but even trees and shrubs fantastically formed of these metals were placed in the imperial gardens at Cuzco. The most ordinary domestic utensils were made of them; and several of their vessels and trinkets are said to have exhibited considerable skill in the workmanship. Mirrors of highly polished stone have been discovered in their sepulchral mounds; but that which gave the Peruvians a decided superiority, in various arts, over the other tribes of the west, was such a knowledge of metallurgy as enabled them to mix copper and tin in such proportions as to form a compound metal hard enough to supply the place of iron. But notwithstanding this advantage, they were lamentably deficient in all the implements necessary for the mechanical arts, and none of their attainments are entitled to be considered as greater than those of a people in the first stage of incipient civilization. The painting, statuary, and carving which adorned their temples and palaces appear to have been very indifferent. Humboldt remarks, that the Peruvians were not unacquainted with symbolical paintings, but that they had nothing at all equivalent to the picture-writing and hieroglyphics of the Mexicans. They made use of knots and threads of various colours, which they called *quippos;* and these strings were used to record events, as well as for purposes of calculation. Their knowledge of astronomy, although exceedingly imperfect, was yet far from being contemptible. The incas, who had discovered the annual revolution of the sun, marked out the summer and winter solstices by high towers, which they erected on the east and west of the city of Cuzco. By the position in which the sun rose and set on the east and west of these, the summer and winter solstices were determined. They also observed the equinoxes, and celebrated the event of the vertical position of the luminary in heaven, by holding a great festival in the temple which they had dedicated to it on earth. They distinguished the months by the moon, and their weeks were called quarters of the moon. Like other ignorant races of men, they were alarmed by eclipses of the sun or moon; but they do not appear to have predicted events by the aspect of the stars, though dreams, and the entrails of beasts, which they offered in sacrifice, were considered as instructive objects of divination.

---

[1] See the Foreign Quarterly Review, No. 35; the article MEXICO in this work; and Humboldt's Researches, vols. i. and ii.

[2] Memoirs of General Millar, vol. ii. p. 188–9.

The government of the incas was a species of theocracy, the sovereign uniting in his own person the functions of priest and king, with both temporal and spiritual domination. The sun was the object of supreme adoration, and the incas were considered as his children, descended from him through Manco Capac, who was believed to be the offspring of their god. They also adored a twofold being named Con Pachacamac, who they believed was the creator of the Peruvians. But although the Peruvian form of government was the most absolute despotism, it was much more mild in its nature, and less oppressive in its operation, than that of the Mexicans. The people were taught, and they yielded, the most slavish submission to their sovereigns; for, after their deity the sun, the incas were regarded with the greatest veneration. Almost every crime was punishable with death; and the incas seldom forgave an injury. It was customary for them to mutilate the faces and limbs of all the individuals taken in a revolted district. As an illustration of the nature of their government, one law may be sufficient. If it were discovered that a priestess of the sun had violated her oath of chastity, she was buried alive, whilst her seducer was tortured to death in the most cruel manner. Even the families of the offending parties were consigned to the flames; and a line being drawn around the birthplace of the two lovers, like the doomed cities of Scripture, it was marked out as a desert for ever. The number of offenders against any of the laws is said to have been extremely few. Their religion, however, was unpolluted by the bloody rites of that of Mexico. The "terrible god," the Moloch of the west, held no sway in Peru. Lambs and other animals were offered in sacrifices, but human victims never bled on the altars of the sun. The national character of the Peruvians harmonized with the genius of their religion, being more gentle and pacific than that of any other people in America. Even their wars are said to have been prosecuted with singular humanity. But the funeral rites of their monarchs accorded ill with this mildness in religion and general manners. At the death of the incas and of other eminent persons, a number of their vassals were buried in the tumuli, along with the dead bodies. The number was sometimes very great. On the death of Huana Capac, the greatest of their incas, above a thousand victims were doomed to accompany him to the tomb. In another particular the manners of the Peruvians were singularly barbarous. Although very well acquainted with the uses of fire in culinary operations, they astonished the Spaniards by devouring both flesh and fish perfectly raw.

Gold and silver were used for ornamental purposes alone, and were never employed as a circulating medium. The produce of the earth was enjoyed in common. The whole being divided by proper officers into four portions, the first was destined for the indigent; the second was set apart for the maintenance of the priests and virgins of the sun, and for other religious purposes; the third was appropriated to the community; and the fourth and last to the inca and his family. The incas spoke a language which was not permitted to be taught even to the nobles, far less to the people; and messages were transmitted to members of his family, from one end of the kingdom to the other, without the bearers of them, who were stationed at regular intervals, understanding the import of the communication which they conveyed. This language was lost a generation or two after the conquest.

That Cuzco was the only city which ancient Peru possessed, as asserted by Dr Robertson, is completely at variance with the accounts of recent travellers, who have found extensive remains in various parts of the country. It was, however, the capital of the empire, and the centre of its wealth and civilization. Throughout the rest of Peru the people appear to have lived chiefly in detached habitations or small villages, with the exception, it may be hazarded, of a few large towns, situated widely apart and in particular positions; for it appears that the Peruvians never built a town or suffered a single house to occupy a spot that was susceptible of cultivation. Little intercourse was maintained amongst the different provinces, for there were no stated markets, as in Mexico, and the inland trade was insignificant. Distinction of ranks was recognised, for not a small proportion of the inhabitants were scarcely above the condition of slaves; but there was no separation of crafts, every Peruvian practising all the arts indiscriminately. That this people could have advanced far in improvement under such a system was impossible; and we are only surprised that they should have attained to such a degree of refinement as they actually reached. The natural character of the Peruvians was also such as to preclude anything like a rapid progress of manners and refinement of life. They were tame and abject; their mildness degenerated into sloth, and their submission into a slavish fear of danger. When all these circumstances are taken into consideration; the vast extent of country over which the inhabitants were scattered, chiefly in hamlets and huts, and having little intercourse with the imperial city; the physical weakness of the Indian race in general, and the natural timidity of the Peruvian character in particular, increased as it must have been by the system of government under which they lived; and the political debility which necessarily attached to a social structure so slenderly constituted as that of Peru; when these things are duly weighed, we shall experience less surprise that the conquest of the country should have been effected, almost without a struggle, by a handful of daring and desperate adventurers.

The first intelligence of the great Southern Ocean, and the country washed by its waters, was obtained by Nuñez de Balboa, Spanish governor of Darien, in 1512, and purely by accident. In one of their numerous inroads into the country adjacent to that in which they gained a permanent footing, a violent dispute arose amongst the Spaniards about the division of some gold. A young cacique or petty prince, who was present, astonished at their contention about a thing which was to him of little value, acquainted them with the existence of a country six suns to the south, where even the utensils in common use were made of the same metal as that about which they seemed ready to shed each other's blood. The eager cupidity of the Spaniards was roused by this welcome information, and no time was lost in preparing for the invasion of this land of gold. Balboa, accompanied by a hundred and ninety of his countrymen, and about a thousand Indians, commenced his journey across the isthmus, which, although only sixty miles in breadth, was so encumbered with natural obstacles, that five and twenty days were spent before he obtained a sight of the Southern Ocean, which he did from a mountain near Panama. The view of this vast expanse repaid the adventurers for their past toils and sufferings. They advanced to the shore with the utmost alacrity; and their leader, rushing up to the middle in the waves, with his sword and buckler, took possession of it in the name of the king his master. The part which he discovered is still designated the Gulf of St Michael, the name which he bestowed upon it. Balboa, however, did not reap the reward which he merited for this important discovery. By an ungrateful government he was superseded in his command; and although afterwards restored to high authority, he fell a victim to the jealousy of the individual with whom he was associated in the government.

For a short time after the death of Balboa, the thoughts of conquering Peru were laid aside; but a new expedition was at length set on foot, at the head of which appeared the famous, or rather infamous, Francisco Pizarro, a soldier of fortune, and formerly in the service of Balboa. Associated with him were Diego de Almagro, a man of as humble extraction as himself, and likewise a soldier of fortune, and Hernando de Luque, who combined the functions of priest and schoolmaster at Panama. Towards the close of 1524, Pizarro sailed from the port of Panama in a small vessel, with only a hundred and twelve followers, to undertake the subjugation of half the western world. We may smile at the disparity between the extent of the enterprise and the paucity of the means by which it was to be achieved, and feel astonished that it should ever have been attempted under such circumstances. But the Spaniards, naturally brave, courted danger, and were enamoured with the excitement of conquest. Exposure to peril had rendered them fearless, and a succession of triumphs had made them arrogant. The season at which Pizarro embarked was the most improper that could have been chosen; for the periodical winds which then began to blow were directly adverse to the course which he wished to steer. But after a series of disasters and disappointments, which he bore with a patience and fortitude worthy of any undertaking, and in defiance of a recall from the governor of Panama, he succeeded, in 1526, in reaching the coast of Peru. After touching at several villages, he landed at Tumbez, a place of some note, about three degrees south of the line, and remarkable for its stately temple and a palace of the incas. Here the golden dreams of the Spaniards were, if possible, more than realized. But for the present they could only feast their eyes on the vision of riches before them; for the force of Pizarro was far too limited to attempt the conquest of the opulent empire thus discovered; and towards the close of the third year from his departure this adventurer regained the port whence he had sailed.

Pizarro immediately repaired to the court of Spain, for the purpose of turning his discovery to advantage. The powers which he solicited were granted him. He was invested with supreme civil and military authority over the country to be conquered, his jurisdiction being declared to extend prospectively two hundred leagues to the southward of the river St Jago. The means of executing this commission he was left to provide entirely from his own resources, which were slender; but they proved sufficient. He returned to his confederates at Panama, and after exerting his utmost efforts, the whole armament which he was able to fit out amounted only to three small vessels, carrying a hundred and eighty soldiers, of whom thirty-six were mounted. His first descent was on the shores of St Matthew's Bay, whence he pursued his march southward along the coast, meeting with little or no resistance, and suffering no calamities except such as were inflicted by the insalubrity of the climate and the sterility of the soil. From first to last, the New World was conquered as much by the terror which the aspect and manners of the invaders inspired in the breasts of uncivilized men, as by force of arms; and the general impression made on the timid Peruvians proved irresistible and paralysing. But another cause contributed to the rapid success of Pizarro. At this very time the country was embroiled in a civil war. When the Spaniards first visited the coast of Peru, Huana Capac, the twelfth monarch from the founder of the state, was seated on the throne of the incas. By his victorious arms he had subjugated the kingdom of Quito; a conquest of such extent and importance as almost to double the power of the Peruvian empire. This prince is represented as alike conspicuous for his pacific virtues and for his abilities in war. He was, at all events, a bold innovator; for, in defiance of the fundamental law against polluting the blood of the children of the sun with any foreign alliance, he espoused the daughter of the conquered monarch; and by this princess he had a son named Atahualpa, commonly written Atabalipa, to whom he left the kingdom of Quito at his death, in the year 1529. To Huascar, his eldest son by a mother of the royal line, was bequeathed the rest of his dominions. This arrangement was productive of a civil war, in which the sovereign of Quito proved victorious; and, to place himself more firmly on the throne, he put to death all the descendants of Manco Capac whom he could seize either by force or stratagem. Huascar himself was a prisoner in his hands, but from political motives his life was spared. This unhappy contest completely diverted the attention of the Peruvians from the circumstance of a foreign invader having violated their soil. It was some time, however, before Pizarro gained information of the events which so opportunely conspired to forward his enterprise; indeed the first intelligence he received was the appearance in his camp of messengers from the rival sovereigns, each soliciting the fatal aid of their common enemy.

Pizarro, as sagacious as he was daring and unprincipled, perceived at once the importance of the intelligence, and the fortunate position in which the affairs of the country were placed for him and his cause. At the head of an ill-accoutred train of a hundred and two foot soldiers, of whom twenty-two were armed with cross-bows, and only three with muskets, and sixty-two mounted followers, he pushed forward from St Michael's, where, in May 1532, he had established the first Spanish colony in Peru. He directed his course towards Caxamarca, a town of the interior, distant twelve days' march, where Atabalipa was encamped with a considerable body of troops. Appearing in the guise of an ambassador, or rather pacificator, his professions were received with inconsiderate credulity; and the inca became the victim of the perfidy of the Spaniard. Relying with unsuspicious simplicity on the honour of the man whom he considered as his guest, Atabalipa consented to give him an audience in that part of the city where he and his followers had established themselves. In the mean time Pizarro had made every preparation for receiving the inca in a manner which he little expected. He arranged his troops in as advantageous a situation as possible, within a square wholly surrounded by a strong rampart or wall of earth; and there he awaited the emperor, who slowly approached with all the pomp of barbaric splendour. The latter was borne on the shoulders of his principal attendants, seated on a throne or couch, resplendent with plates of gold and silver, enriched with precious stones, and adorned with waving plumes of the most gorgeous hues. Behind him came the chief officers of his court, and bands of singers and dancers attended the cavalcade, whilst the Peruvian army, to the number of 30,000 men, swarmed all over the surrounding plain. With matchless perfidy Pizarro instructed a priest to inform Atabalipa, that the vicegerent on earth of the God whom they worshipped had made a donation of all the nations of the New World to the king of Castille, their master, and that he must accordingly surrender Peru. At the same time he was required to renounce the service of the sun, and become a convert to the religion of the Spaniards. Astonished at this extraordinary proposal, he asked the priest for a sight of his credentials; and a breviary being handed to him, he lifted it to his ear.

"This," said he, "is silent; it tells me nothing;" and he dashed it to the ground with disdain. The wily monk, who appears to have been exactly the tool which Pizarro wanted, ran towards his countrymen, calling out that the word of God had been insulted, and that they ought to take immediate vengeance on the impious dogs who were guilty of such a profanation. At once the signal for assault was given, and an indiscriminate massacre of the unresisting Peruvians took place. In vain did the wretched fugitives seek shelter from the avenging steel of the Spaniards. They were pursued even within the sanctuaries of their religion, and cut down around their altars with unrelenting barbarity. Atabalipa himself was taken prisoner, and put into close confinement. A proposal of the inca to ransom himself by paying an enormous quantity of gold was instantly caught at by Pizarro; and the devoted subjects of the captive king, with eager alacrity, obeyed his call to bring him their treasures in order to procure his liberty. Meanwhile, Almagro arrived with a reinforcement of Spaniards equal to that already in the country. The rapacious bravoes who composed it, being as yet unglutted with the spoil of the richest country in the world, urged Pizarro to put the inca to death, and thus clear the way for a thorough plunder of the whole empire. The chief of this banditti had himself previously determined on taking this step, and probably only waited for the proposal coming from the troops in order to carry it into execution. After performing a ceremony preparatory to execution (it would be an abuse of language to call it a trial), the Spaniards condemned the inca of Peru to be burned alive, which merciless sentence was, as a great favour, mitigated to strangling, and the unhappy victim suffered accordingly. Amongst a list of imaginary crimes which were laid to his charge, there was one of which he had really been guilty, namely, putting to death his brother Huascar. This cruel and unnecessary deed of blood he was induced to commit from fear lest, in his own helpless situation, his rival to the throne might join the invaders against him. But Spaniards were not competent to try him for such an act; he was only amenable to his own country; and the allegation was as irrelevant as the other parts of the charge in this solemn mockery of justice.

The murder of Atabalipa was soon followed by a revolution in the affairs of the Spaniards, whose barbarous inhumanity now rendered them odious to the Peruvians. Even amongst themselves were found a few persons not altogether divested of pity and a sense of justice; and the dread of impending danger from the Indians now uniting against Pizarro, alone restrained these soldiers within the bounds of discipline. At Cuzco, the partisans of Huascar elevated his brother Manco Capac to the throne of the incas, whilst Pizarro set up Taparpa, the son of Atabalipa, as emperor. But this prince was relieved by death from the degradation of being innocently accessary to the humiliation of his country. No other person having been invested by the Spaniards with the insignia of mock royalty, the title of Manco Capac was universally acknowledged. The attempts of the Indians, however, to arrest the progress of the invaders proved unavailing; but the latter quarrelled amongst themselves about the division of the spoil. Ferdinand Pizarro, the brother of the general, had been sent to the court of Spain to report the progress of spoliation, and to deposit a part of the booty. Honours were conferred upon him, and his brother obtained an additional grant of land, whilst he himself was invested with the jurisdiction of a very large tract of country lying still further to the southward. No sooner did Almagro hear this than he attempted to seize Cuzco, alleging that it lay within the limits of his government; and a civil war between his partisans and the Pizarro faction was only prevented by an accommodation, on the singular footing that Almagro should indemnify himself by attempting the conquest of Chili. This reconciliation left the general at liberty to settle the internal policy of his province. He divided the country into districts, over which magistrates were appointed to preside; and he removed the seat of government from Cuzco to Lima, which he named Ciudad des los Reyes. He likewise despatched some of his most distinguished officers to inspect those provinces of the empire hitherto unvisited by the Spaniards; but this imprudent feeling of security nearly proved fatal to him. The Peruvians, with Manco Capac at their head, seeing the Spaniards weakening themselves by dividing their force, seized the opportunity of making a desperate effort to avenge their wrongs and to rid themselves for ever of their oppressors. This insurrection took place in the year 1535–1536. The Spanish historians, probably to exalt the prowess of their countrymen, assert that an army of more than two hundred thousand men was collected, part of which invested Lima, where the governor was closely shut up, whilst a still larger body of men laid siege to Cuzco. Half of the city had already fallen into the hands of the Peruvians, and the besieged were reduced to the most desperate condition, when Almagro suddenly made his appearance in the neighbourhood. Upon his arrival, his assistance was solicited by both parties; but the inca, despairing of success in his negotiations with Spaniards, attacked Almagro during the night. Spanish valour and discipline, however, prevailed over the greatly superior numbers of the Indians, who were repulsed with terrible slaughter, and the governor of Chili advanced unopposed to the gates of Cuzco. Over the capital of the incas his authority was now fully recognised, though not without an affray, in which several Spaniards were killed. But very soon afterwards matters began to assume a serious aspect; in short, it now came to the issue of arms, whether Pizarro or Almagro should remain master of Peru. The latter was at first completely successful against the brothers of the general; but in an engagement with Pizarro himself he was defeated and taken prisoner. The conquerors behaved with a cruelty which struck horror into the minds of the barbarians, who had assembled out of curiosity to see the battle. Almagro, after languishing some months in prison, was at length formally tried and condemned to death; which sentence he underwent by being first strangled in private, and afterwards beheaded in public.

In the meanwhile intelligence having reached the court of Spain of the dissension which had taken place in Peru, the king appointed a new governor, who, on his arrival, was to assume the supreme command, provided Pizarro had fallen, which proved to be the case. Almagro left a son by an Indian woman, and this youth he appointed his successor, by virtue of a power granted him by the emperor. The partial division of the spoil which had been made by Pizarro and his brothers tended to alienate many of the Spaniards from their cause. Great numbers of the disaffected repaired to Lima, where the house of young Almagro was always open to receive them; and here a conspiracy was formed against the life of Pizarro, at the head of which was Juan de Herrada, an officer of distinguished abilities, and who had had the superintendence of Almagro's education. The natural intrepidity and fearless disposition of the general proved his ruin; for, utterly disregarding the warnings which were given him of approaching evil, he took no measures either to discover the plot or to protect his own person from violence. In this state of fancied security access to his palace was easily gained by the conspirators. On the 26th of June 1540, Herrara, with eighteen of the most determined of his followers, sallied from the house of Almagro, and advancing through the streets, shouted "Long live the king, but let the tyrant die." He entered the palace of Pizarro without opposition, and gained the apartment where his victim was conversing with some of his friends, having just risen from table. His resolute mind no form of danger could appal: he hastily snatched a sword and buckler, with which he maintained the unequal contest, in a manner worthy of his past exploits. But friend after friend was cut down at his side; and, no longer able to turn aside the numerous weapons so furiously aimed at his life, he received a deadly thrust in his throat, sunk to the ground, and expired. Thus perished by the swords of assassins Francisco Pizarro, the conqueror of Peru, a man who in mere valour was probably never surpassed; but whose injustice, rapacity, and cruelty rendered him unworthy of a better fate.

After the death of Pizarro, young Almagro was placed at the head of the government; but his career was short and troubled. The new viceroy having arrived from Spain, he refused to relinquish his pretensions, and a struggle ensued, which proved fatal to himself and all his followers. Another insurrection, however, broke out under Gonzales Pizarro, who had just returned from a most disastrous expedition into the country to the east of the Andes, and was thus prevented from taking any part in the revolutions which had so rapidly succeeded each other in Peru. To oppose this new aspirant to viceregal power, Nuñez Vela, governor of Lima, assembled a motley army of Indians and Spaniards; and, after various successes on both sides, a decisive battle was fought under the walls of Quito, in which Nuñez perished, along with the greater number of his followers. But another viceroy arrived from Europe in the person of the licentiate Pedro de la Gasca, and against him it was necessary for Gonzales to take the field. But many deserted his standard to rally round that of a person who was invested with a lawful authority to govern them; and those whom the tyranny of the usurper had driven to forests and caverns now quitted their hiding-places and joined the royalists. On the 9th of June 1548, an engagement took place near Cuzco, in which the last of the Pizarros, deserted by his followers, was taken prisoner, and afterwards beheaded. Such is the last event of any importance connected with a history, every line of which is written in blood. During these ferocious contentions, in which the rancour of enmity was rendered more intense by avarice, honour, the proverbial virtue of the Spaniard, was utterly disregarded. There was hardly one of them who did not abandon the party which he had originally espoused, and betray or desert his former associates. This is not to be wondered at when we reflect that most of the followers of Pizarro were needy adventurers, soldiers of fortune, exactly similar to those who had for centuries swarmed in various countries of Europe, and who sold their services to the best paymaster. The same mercenary principle appears to have been acted upon by the Spaniards in Peru; they attached themselves most tenaciously to the leader who held out the richest bribe. Petty insurrections continued to disturb the country for several years; and most of the first invaders, as well as a large proportion of the licentious soldiery whom the fame of their success had drawn thither, perished in their contests one with another. Ultimately the devoted land was thus cleared of those turbulent and desperate spirits which had been let loose upon it, and the royal authority was finally as completely established in Peru as in the other Spanish provinces.

The whole of the dominions of Spain in the New World were at first divided into two immense governments; one subject to the viceroy of Mexico, and the other to the viceroy of Peru. But the latter was, at two subsequent periods, reduced in order to give such extension to other provinces as should entitle them to the rank of viceroyalties. In the year 1718, the province, or, as it was sometimes called, the kingdom, of Quito, was detached from Peru, and added to the government of New Grenada. In the year 1778 the provinces of the Rio de la Plata, Potosi, Charcas, Chiquitos, and some others, were detached from the jurisdiction of the Peruvian viceroy, and erected into a separate government, of which Buenos Ayres was made the capital. To these four governments alone was attached the dignity of a viceroyalty. Guatemala, the provinces of Venezuela, Caraccas, Cumana, and Chili, were severally formed into distinct jurisdictions under a captain-general. Having already given a view of the colonial system of administration under which the Spanish territories in the New World groaned for nearly three centuries (see the article MEXICO), we shall only here advert to two distinct features of the tyranny which was exercised over the aborigines of Peru. These were the *mita* and the *repartimiento*. The former was a civil conscription, by which the population of every district was compelled to furnish annually a certain number of labourers for the service of the proprietors of the lands or mines. It is true that under the incas a great body of the natives were held in a state of degrading vassalage, so that a change of masters did not involve a change of condition in as far as mere labour was concerned; but the effects of being condemned to work in the mines for a fixed period proved most fatal to them. By the regulation, every Indian from the age of eighteen to fifty was pressed into the mining service for six months once in every three years and a half. On these occasions they were under the necessity of quitting their homes and families, relinquishing their professions, and repairing, it might be, many hundred miles to some inhospitable spot, where, it is said, scarcely one Indian in five survived the first year of his labours. More than twelve thousand Indians were annually subject to the *mita* conscription of the single province of Potosi; and it is computed that upwards of eight millions of human beings perished in the mines of Peru alone.[1] The Indians were also pressed into the employment of the governors of provinces and others; a species of servitude which was perfect liberty compared with that of the mines.

The *repartimiento* was a privilege originally granted to the corregidors or governors of districts, empowering them to furnish to the Indians, at a fair price, articles of necessary consumption. In course of time this privilege degenerated into a compulsory and oppressive exaction. Not only were the most worthless commodities forced upon the Indians, who were compelled to pay for them doubly or even triply, but also articles for which they had no earthly use; for instance, razors for men who had no beards, spectacles for those who had "the eye of the hawk" even in old age, and silk stockings for Indians who go barefoot. Even luxuries, the very use of which was unknown to them, formed part of the supplies which they were compelled to purchase. The collection of the royal tribute afforded the corregidor another pretence for exactions; whilst the priests to whose spiritual guidance the Indians were assigned plundered them without mercy, of all that escaped the rapacity of the governors. "The atrocities committed by these wolves in sheep's clothing," says Miller, "would almost surpass belief, were they not given on the authority of such men as the Ulloas, and had we not before us recent facts which confirm their statement." But the bow, however elastic, may be bent until it recoils. An insurrection broke out in the year 1780, and threatened the most disastrous consequences to the Spaniards; but it ultimately proved fatal to Tapac Amaru and the other Peruvians engaged in it.

---

[1] Memoirs of General Miller, vol. i. p. 5. There is probably great exaggeration in this estimate; for, besides the difficulty of accounting for such a mortality in mines which subsequently have not proved at all so mortal, we learn from Ulloa that a considerable proportion of the workmen served voluntarily. Certain it is, however, that wherever mines were wrought in a compulsory manner, an alarming decrease took place in the Indian population. In a memorial presented to Philip III. in 1609, Captain Juan Gonzales de Azevedo asserts, that in every district of Peru in which Indians were compelled to labour in the mines, their numbers had been reduced to one third, and in some places to one half, of the population in 1581. Amongst other causes of this decrease may be mentioned, the civil wars; the expeditions of the Spaniards, in which vast numbers of the Indians perished; the small-pox, peculiarly fatal to Indians; and the immoderate use of spirituous liquors.

In the celebrated war of independence, which was fomented in the year 1808, and broke out over all the Spanish possessions in South America two years afterwards, Peru was the last to join; and it was there that the royalists made their final stand in behalf of the mother country.[1] They were powerful enough to restrain the spirit of revolt until the year 1821, and probably would have done so for a much longer period, had a foreign force not come to the aid of the patriots. It soon became evident to those who had established the independence of Chili, that the conquest of Peru was necessary to its security; and the project for achieving it attracted to their cause many military adventurers from Europe, now restored to profound peace by the fall of Napoleon. Amongst others, Lord Cochrane, and several English officers who had distinguished themselves in the naval service, found employment in the fleet, which was speedily equipped, and which, in discipline, though not in force, soon attained so decided a superiority over the navy of Spain as to give it the command of the navigation of the South Sea. Being to windward of the Spanish ports, it was easy at any time to choose the point of attack. Under San Martin was formed an army of 5600, which, with the fleet, consisting of one ship of sixty-four guns, one of fifty, one of thirty-six, and one of thirty-two, besides some corvettes and transports, sailed from Valparaiso, in the latter end of 1820, and reached Lima in February the following year. The troops were landed to the northward of Callao, and continued, without making any great exertion, till May, when the garrison of Lima being much straitened, an armistice was concluded.

Pezuela, then the viceroy of Lima, was opposed by the audiencia and the municipality, who censured him for not adopting measures sufficiently energetic to repel the invaders. The same disposition prevailed amongst the officers of the army, who at length resolved to depose Pezuela. He made no resistance; but having quitted the government and country, the command was placed in the hands of Don José de la Serna on the 29th of January 1821. The troops of La Serna were not much superior in number to the invaders; but some of them having gone over to San Martin, turned the scale in favour of the latter. Lima continued to be straitened by the general, and Callao to be blockaded by Lord Cochrane, who performed one of those acts of desperate valour which struck astonishment into the Spaniards. With the boats of his little squadron he entered the port of Callao, and, under the guns of its tremendous batteries, boarded, captured, and carried off one of their largest ships of war, with more men on board than were in all the boats that attacked her.

After some months had elapsed, a convention was agreed on, when La Serna with his army marched out of Lima, and San Martin with his forces entered it several days afterwards. A garrison was, however, left by the royalists in Callao. The protracted operations had given time to remove the most valuable property, which, with the females of the best families, and the non-combatants, reached the mountainous districts. San Martin, in the possession of Lima, was in the same condition as La Serna had been for some months before, with many mouths besides those of his army to fill, and his intercourse with the country that furnished provisions intercepted; but he had the advantage of naval superiority, and could draw supplies from the coast, though, till Callao was taken, the difficulty of landing rendered the arrival of such supplies very precarious.

As a measure of the last importance, San Martin sought to implant the feeling of independence, by some act which should bind the inhabitants of the capital to that cause. On the 28th of July 1821, therefore, the ceremony of declaring and swearing to maintain the independence of Peru took place. The troops were drawn up in the great square, in the centre of which was erected a lofty stage, where the independent flag of Peru was for the first time unfurled; General San Martin, who displayed it, exclaiming, "From this moment Peru is free and independent, by the general wish of the people, and by the justice of her cause, which God defend." Oaths of fidelity to the new government were afterwards taken, and, on the 3d of August, San Martin declared himself protector of Peru, and assumed the supreme civil and military command. He at the same time stipulated, that as soon as the country should be free from a foreign enemy, he would resign the command to the individual whom the people should be pleased to place at the head of the government. The offices of government were filled up by him, and General de las Heras was appointed commander-in-chief of the army. Amongst the first legislative acts of the protectorate was a decree declaring that the children of slaves born in Peru subsequently to the 28th of July preceding should be free. This was followed by another abolishing the tribute, and forbidding the name of Indians to be applied to the aborigines, who were thenceforth to be denominated Peruvians, like the Creoles. Others of less importance were added to the list of benefits conferred by the new government; but in the mean time a disgraceful scene was exhibiting at Callao, where Lord Cochrane, having come to an open quarrel with the protector, was endeavouring to gain possession of the fortress by negotiation, intending, should he be successful, to hoist the Chileno flag, in opposition to the views and policy of San Martin. The true cause of the misunderstanding it is not very easy to ascertain, nor is it of much importance. On the 21st of September the fortress of Callao surrendered to the protector; and on the 26th of the same month, he, in the capacity of commander-in-chief of the liberating army, ordered Lord Cochrane to quit the coast of Peru. General Canterac, who had meditated an attack on the patriots, for the purpose of relieving the castle of Callao, retreated to the Cordillera; so that, with no one near to create any alarm, San Martin was at liberty to take steps for the consolidation of his government and the termination of hostilities.

Unfortunately, however, recent events would appear to have thrown the inhabitants into a fever of excitement, productive of cabals which cast fatal embarrassments in the way of any energetic measures being taken. The protector, in endeavouring, with the very best intentions, to promote those who had declared for the patriot cause, gave great umbrage to certain persons by his appointments, and they unfortunately led to a disastrous prolongation of the contest. General Tristan, who had received the command of a body of troops at Ica, allowed himself to be surprised and his retreat cut off by Canterac, who took one thousand prisoners, besides some pieces of artillery, and other spoil. This reverse threw a damp over the minds of the people, who had previously lent their cheerful aid to the cause; but any seriously bad effects were prevented by the victory which the patriots gained over the royalists at Pinchincha on the 24th of May 1822. Passing over a short visit which the protector of Peru paid to the liberator of Colombia at Guayaquil,

---

[1] The events connected with the early part of the revolutionary struggle will all be found recorded under the heads of BOLIVIA, COLOMBIA, CHILI, and BOLIVAR.

Peru.

and the result of which was not so satisfactory as had been anticipated, we find the protector resuming the supreme command on the 21st of August. Secure of the support of the army, he would have experienced little opposition in quelling the spirit of insubordination manifested both by the civil authorities and the people, had he resorted to compulsory measures; but this would have been in opposition to his usual policy, and might have justified the clamours of his enemies. One alternative alone seemed left to him. Agreeably to a decree issued by the council of state, deputies had already been summoned; and on the 20th of September the congress was installed in due form. The protector repaired in state to the hall of the deputies, where, divesting himself of the insignia of supreme power, he resigned his authority into the hands of the representatives of the people. He then withdrew, and immediately set out for his country-seat near Callao, leaving behind him a proclamation as his farewell address. This document embodied his reasons for retiring, and contained some wholesome advice to the new republic. Congress lost no time in appointing a new executive, under the title of the Junta Gubernativa; and Xavier de Luna Pizarro was chosen president of the congress. One of the first acts of that assembly was to decree that San Martin should bear the title of Founder of the Liberty of Peru, and enjoy a considerable pension; whilst the thanks of the Peruvian nation were likewise awarded to Lord Cochrane for his achievements in the cause of Peruvian independence.

The proceedings of the new government were marked by feebleness and discord. An unsuccessful effort to reduce the royalists increased popular clamour against the government junta, which was at last expelled from power, and Colonel Don José de la Riva Aguero was made president of the republic. Santa Cruz, a Peruvian, who in the sequel greatly distinguished himself, assumed the chief command of the army; and it was determined in a council of war to make another effort in the Puertos Intermedios. Whilst they were employed in this enterprise, General Sucre arrived at Lima with 3000 Colombian troops; but this force, with 2000 Peruvians, partly militia and partly the wreck of a former army, was found insufficient for the protection of the capital, against which Canterac advanced at the head of 9000 well-disciplined men. Lima was accordingly abandoned by the patriots, and immediately taken possession of by the royalists, who, however, soon afterwards evacuated it, after having exacted heavy contributions from the remaining inhabitants, and destroyed the mint. Both Generals Santa Cruz and Sucre, who with a united army might have accomplished something of moment, proved unsuccessful; and the former allowed himself to be out-generalled by Canterac. The cause of independence in Peru seemed hanging by a thread, which it required little exertion to break, when the celebrated Bolivar made his appearance in Lima on the 1st of September 1823. He was received with the greatest enthusiasm, and was immediately invested with supreme authority, military and political. Great activity was now infused into the measures of government; and, acting in the capacity of dictator, Bolivar dissolved congress, and levied an army, with which he sallied from the capital on the second week of November. Riva Aguero, who refused to join him, was imprisoned by his own troops, who immediately submitted to the dictator. But a fresh misfortune awaited the patriots in the mutiny of the soldiers at Callao. The consequence was, that this town, along with the city of Lima, once more fell into the hands of the royalists. The cause of independence in Peru now seemed desperate; but the conduct of Bolivar at this critical moment is deserving of the highest praise. By his firmness, activity, and seasonable severities, he checked farther defections, and obtained the respect and entire confidence of every true patriot. Nor did he disappoint public confidence; for in less than a year from that time South American independence was finally established.

In the month of July 1824 the liberating army commenced its march towards Pasco in three divisions, two of which were Colombians, headed by Generals Lara and Cordova; and one was Peruvian, under Lamar. General Sucre was chief of the staff of the whole army. In his preparatory measures for facilitating the passage of the troops to Pasco, a distance of two hundred leagues, through the most mountainous region in the world, this officer displayed great skill; and the army, 9000 strong, reached its destination in safety, and unmolested by the royalists. Various manœuvres now took place; and in an action of cavalry the patriots inflicted a severe blow on their adversaries. A series of marches and countermarches occupied the months of August, September, October, and November; and on the 6th of December the patriots reached the village of Quinua; whilst the royalists, by entering Guamangilla, cut off their retreat, and placed them in an extremely critical situation. On the 8th the viceroy, La Serna, moved from this position, and occupied with his whole force the heights of Condorkanki, within gun-shot of the encampment of the patriots. Between the opposing armies lay the plain of Ayacucho; and as a battle on the following day had become inevitable, on this plain were to be decided the destinies of South America. It is in shape nearly square, about a league in circumference, and flanked right and left by deep and rugged ravines. The eastern boundary is formed by the abrupt and savage ridge of Condorkanki, whilst its western extremity is the Indian village Quinua, a little distance in front of which lay the patriot army, not 6000 strong, that of the royalists being fully one third more numerous. Next morning, the 9th of December 1824, the expected conflict took place, and continued for about an hour, when the royalists were defeated with great loss. Indeed their army may be said to have been almost annihilated; for 3200 rank and file, amongst whom was the viceroy, were made prisoners of war, the remainder dispersing in a state of total disorganization in all directions. The battle of Ayacucho is pronounced by Mr Miller "the most brilliant ever fought in South America;" and it may be considered as the last regular engagement, although not the last struggle, in which Spain was engaged for the recovery of her revolted colonies. Rodil still held out at Callao for the mother country, with the most desperate tenacity. It was a gallant, but at the same time an unnecessary and hopeless defence, when nearly the whole of the vast continent had declared for the cause of independence. Many families of the highest rank, who had shut themselves up with this determined individual, were exterminated by disease or famine. For thirteen months he sustained, unaided, bombardments both by sea and land, rendered still more terrible by the accumulated miseries of pestilence and nearly utter want of food. He capitulated upon honourable terms on the 19th of January 1826, and thus the last link of the chain which had bound seventeen millions of Americans to the tottering monarchy of Spain was finally broken.

But although thus happily relieved of the presence of a foreign enemy, these infant republics could not agree amongst themselves; and, from the period of their establishment down to the present time (1838), their history is disfigured by a series of altercations, intrigues, plots, and counterplots, which have materially retarded their proper consolidation, and the advancement of the arts of peace. Bolivar was exceedingly desirous that the constitution which he had framed for Upper Peru, now named after him Bolivia, should be adopted by Peru proper; but public opinion was strongly opposed to his wishes. The Peruvians, also, apparently the most fickle of the fickle, began to feel their Colombian allies a burden to them. In short, whilst the national manners and habits of the Colombian troops were the opposite of congenial to them, the dislike with which the latter were regarded, from this dissimilarity of tastes, increased the hatred of the Peruvians for the Bolivian code. This spirit soon led to the formation of a strong party, which in its turn gave birth to a conspiracy, having, it was said, for its object the assassination of Bolivar himself, and the expulsion of the Colombians. It was fortunately discovered and crushed before any evil was effected; but it served to throw the affairs of Peru into greater disorder than ever, and this was increased by the announcement of Bolivar's determination to quit the country. The public mind became fearfully excited by this intelligence, and every argument and remonstrance was employed to induce him to remain amongst them, lest his departure should reduce their government to a state of perfect anarchy. On the 17th of August the electoral college of the province, and that of the city of Lima, resolved that the Bolivian constitution should be adopted in Peru, and that Bolivar should be named Presidente Vitalicio. Their example was followed by the other provincial colleges, with the exception of that of Tarapaca. Matters of importance, however, soon peremptorily required the presence of the liberator in Colombia, and Santa Cruz was left at the head of the government.

No sooner was Bolivar gone, than the popular spirit of resistance to the Bolivian code manifested itself, and the Peruvians began to devise measures for getting rid of that system and of the Colombians together. This dissatisfaction naturally terminated in a revolt, at the head of which was Colonel Bustamente, a young Colombian. The chief officers of the Colombian army were arrested and sent home, and not long afterwards they were followed by their troops. The people now unanimously denied the right of electoral colleges to decide upon the adoption of a form of government; and when the new congress assembled at Lima on the 4th of June 1827, the Bolivian constitution was disdainfully thrown aside, the Peruvian constitution of 1823 being declared to be in force. General Lamar was chosen president of the republic, a nomination which at first gave universal satisfaction; but he soon increased the number of the troops to such an extent as to embarrass the revenues, which, it may well be believed, were sufficiently limited. The reason of this augmentation of the army soon became apparent in a furious and ill-judged proclamation of war against Colombia. The menaces of this state might furnish a plausible plea for taking a step which might be pronounced as rash, considering the wavering condition of all these infant republics; but Peru appears to have been the original aggressor. There were various motives for this declaration of war on the part of Peru, one of which was the desire of taking possession of Guayaquil, and of rendering it a Peruvian port; and on the part of Colombia the principal motive was the non-payment of the debt due by Peru, and amounting to about 3,595,000 dollars. But the foundations of the dispute were deeply laid in personal animosities and national jealousy. War being therefore determined on, Lamar entered the Colombian territory at the head of a considerable army; and at Tarqui, near Jiron, in Quito, a sanguinary conflict took place on the 27th of February 1829. The battle was obstinately contested, but terminated at last in favour of the Colombians. On the following day, preliminaries of peace were agreed to, the mild terms of which were highly creditable to the moderation and equity of the conquerors. The chief stipulations were, that neither republic should interfere in the affairs of the other, and that Peru should discharge the debt which it owed to the Colombian army. The imbecility which Lamar manifested on this occasion gave rise to a conspiracy against him, and he was formally deposed on the 29th of June by General La Fuente, who became vice-president. A plot was, however, formed against La Fuente, and he was expelled from the vice-presidency. General Gamarra was subsequently appointed president, but soon afterwards relinquished the office in favour of Orbegoso. During the early part of the year 1834 the ex-president Gamarra, along with Generals Bermudez, Frias, and Vargas, took arms against the president, and seized Junin, Cuzco, Puno, Ayacucho, and several other districts, avowing their intention of erecting the southern provinces into a separate state, of which Cuzco was to be the capital. At first the revolt was crowned with some success; but in the month of April, Bermudez's army, consisting of about 1200 men, suddenly deserted him, and went over to the president; and shortly afterwards Gamarra was totally defeated by General Miller. On the 24th of February 1835, General Salavery, who commanded the garrison at Callao, instigated the troops to declare against the government at Lima, and on the following day took possession of the city, declaring himself supreme chief of the republic. The president Orbegoso, with about 200 troops, retired to Pasco. Salavery having swelled his force by the troops which had in the previous year revolted under Gamarra, extended his authority over nearly the whole of Peru. Orbegoso, unable of himself to recover his lost power, retired within the limits of Bolivia, and applied for assistance to Santa Cruz, the president of that republic. Santa Cruz joined them at Arequipa with a Bolivian army, and the united forces entered Peru, advancing as far as Cuzco. Here the army of Salavery was stationed under the command of Gamarra, for the usurper himself found it necessary to remain at Lima, to maintain his authority against the odium excited by his arbitrary exactions. The two armies delivered battle at Yauacocha on the 13th of August, when Gamarra was totally defeated, the greater part of his troops having gone over in a body to the enemy. Salavery lost no time in making preparations to defend himself to the last extremity within the walls of the capital. He called out a levy *en masse* of the province, including all freemen of colour between the ages of fifteen and forty-five, without exception, and declared, that if his orders were not obeyed, and a stout defence cordially prepared for, he would set fire to Lima as soon as Orbegoso and Santa Cruz should appear before it. He changed his intention, however; and having collected a body of about 2500 men, took the field, and posted himself on the heights of Challapampo, to the north of Arequipa. Towards the end of January 1836, the united forces of Orbegoso and Santa Cruz, amounting to double the number of those of Salavery, advanced to attack him. But he had fortified himself in such a manner that it became necessary to construct works, which, however, were soon completed. In order to cut off his retreat, and also intercept his communication with some vessels which had been prepared to be sent against Bolivia, General Miller was despatched with a sufficient force, and on entering Isla he made prisoners a general and some other officers destined for the Bolivian expedition. In the mean time, Santa Cruz, finding it impossible to attack Salavery in his fortified position, adopted a stratagem which proved completely successful. Having ordered his army to make such a retrograde movement as made it appear that he was in full retreat, the rebel army, believing this to be the case, began to debouche from the pass of Tingo on the morning of the 7th of February. Santa Cruz, seizing the favourable moment for attacking the enemy, fell upon them with great promptitude and vigour. The combat was obstinate, but the issue was not at any period doubtful. Salavery was completely defeated; and so well concerted had been the plans of Santa Cruz, that very few escaped, excepting such as dispersed themselves singly over the country. Amongst the prisoners were 220 officers, including Salavery himself, who, along with seven other officers, two of whom were generals, were tried by a court-martial, condemned to death, and shot on the 18th of February 1836. The port of Callao, Lima, the squadron destined for

Bolivia, and all the provinces of Peru, immediately submitted to the restored government.

It now appeared doubtful, however, whether the president of Bolivia had been altogether the disinterested ally which he had at first appeared, and whether Orbegoso had not purchased his assistance by secret engagements. At all events, it was now discovered that Peru was of too great extent to be governed as one state. An assembly of deputies from the southern departments was held at Sicuani on the 17th of March, under the protection and guarantee of Bolivia, when the independence of these departments was solemnly declared, and a new state formed, called South Peru, composed of the departments of Arequipa, Ayacucho, Cuzco, and Puno. The chief power was intrusted to General Santa Cruz, as supreme protector of South Peru. In the month of July of the same year, a similar assembly of deputies from the northern departments of Junin, Lima, Libertad, and Amazonas, convoked by Orbegoso, followed the example of the southern provinces, and formed themselves into an independent state, under the name of North Peru, Orbegoso being appointed president.

During the year 1837, these republics continued in an unsettled state, and the old differences with Chili led to a declaration of war on the 17th of May, the united provinces of Rio de la Plata having joined Chili against the Peruvio-Bolivian confederation. Fortunately, however, after menacing each other for a few months, a treaty of peace was concluded between Chili and Peru, on the 17th of November 1837.

Con- tion.

The constitution established by a congress of the three confederated states of North and South Peru, and Bolivia, is modelled upon that of the United States of North America. The government consists of three powers, namely, the legislative, the executive, and the judiciary. Each of the three republics has its own distinct congress; and, collectively, they may be said to form a federal republic, united to one another for mutual support and protection. Every second year a general congress is assembled, and is composed of a senate and chamber of representatives. The members of the senate are elected for life, thirty candidates being sent from the different departments of the confederation, from which number the president chooses fifteen. To become eligible for a senator or representative, the candidate must possess landed property, or an income arising from some branch of industry, of 2000 dollars for a senator, and of 1000 dollars for a representative. The head of the confederation is chosen by the general congress, out of six candidates proposed by the three republics. This head of the government is elected for ten years. He may be accused and condemned by the general congress for the crime of high treason, or if he attempt to hold the reins of government beyond the lawful period fixed by the constitution. The ministers of state, consuls, diplomatic agents, magistrates, and so forth, are responsible to the general congress, but can only be accused by the chamber of representatives. The congress by which the form of government was agreed to, appointed General Don Andre Santa Cruz protector of the Peruvio-Bolivian confederation for the first period of ten years. Santa Cruz is thus virtually at the head of three independent states. Although, nominally, Orbegoso has been president of North Peru since the 30th of December 1833, he cannot be viewed in any other light than in that of a vice-president, who governs the internal affairs of one of the states of a federal union, the supreme head of which is the fortunate soldier above named. With regard to the constitution of the individual states, little else has yet been agreed to, excepting that the government of the countries shall be intrusted to a senate and house of representatives.

By the division of Peru which took place, the departments of Lima, Libertad or Truxillo, Junin, and the Pampas, form one republic, under the name of *North Peru;* and the departments of Arequipa, Ayacucho, Cuzco, and Puno, another republic, under the name of *South Peru.* But as the limits of each are yet imperfectly defined, and as they are still to a certain extent united, we shall now proceed to give a general description of them as forming one country.

Peru.

Territorial divisions.

The territory of Peru is separated from the republic of the Equator on the north by the river Tumbez, in latitude 3. 34. south, but for about three geographical degrees this part of Peru is a comparatively narrow peninsula, projecting from the main body of the country. In about latitude 6. 30. south, an imaginary and very irregular line separates it on the north, first from the republic already mentioned, and afterwards from Brazil. On the east and south-east it is separated from the latter country partly by the river Itenez, partly by the river Madera, the great tributary of the Amazons, and partly by a line drawn through barbarous regions, which may be said to belong to either country or to neither. Throughout its whole extent on the west and south-west it is washed by the Pacific Ocean; and on the south it is bounded by Bolivia, the limits of which are not yet settled; but the most southerly land of Peru does not extend beyond the twenty-second parallel of south latitude. From this point, as far towards the equator as fifteen degrees south nearly, the country is only a long and narrow strip of land, forming the province of Arequipa, but beyond this meridian it enlarges prodigiously. In longitude it extends from about 62. to 82. west from Greenwich.

The entire length of Peru from north to south, including the long and narrow peninsula of Arequipa, is estimated at fifteen hundred miles; but its coast-line, which is winding, and has an oblique general bearing from north-west to south-east, cannot be less than 2100 miles. The breadth of Peru is also very great towards its northern boundary, but 700 miles may be taken as its average extension from west to east. According to the careful estimate made by Humboldt, Peru comprises an area of 41,500 square leagues.

Western Peru.

The surface of this immense territory is of the boldest and most varied description. By far the most striking physical feature of all the countries of South America bordering on the Pacific is the colossal mountain-ridge of the Andes, which traverses them from south-east to north-west, in a line nearly parallel with the coast, the bendings and windings of which it follows with remarkable fidelity. Humboldt, who has carefully traced the course of these mountains, describes them as separating in the vicinity of the celebrated city of Potosi, in 19. 35. of south latitude, into two parallel chains. These, however, reunite at the northern extremity of the great basin of Lake Titicaca, between latitude 14. and 15., and so form again an undivided ridge, which runs parallel with the coast line to the northern extremity of Peru, and beyond it. There are, however, other chains, apparently branches of the grand ridge, which have a general bearing from south to north, and in some parts enclose elevated tracts of table-land. In the western or Pacific ridge, immense summits are seen from the cities on the coast, towering in lofty succession above the region of perpetual snow; but the mightiest part of the range is situated in Bolivia. Between the Andes and the Pacific Ocean extends the plain or western part of Peru, and few countries of the globe present a more singular physical character. It is a belt or zone of sand nearly two thousand miles in length, and the average breadth of which is not more than thirty miles. In some parts it is as little as seven, and in others it exceeds fifty miles in width; and in this enormous stretch of country, the general character of which is aridity, there are intervals of many leagues between the different towns and cities, in which neither inhabitants nor any traces of vegetation are visible. No rain falls throughout the whole of this desolate Sahara of the west, and thunder and lightning are unknown. In explanation of these singular circumstances, it has been conjectured, that the chain of the Andes, which runs along its eastern boundary like an immense rampart, to repel the encroachments of the deep, intercepts the clouds which come laden with moisture from the Atlantic, and that the constant winds from the south drive the vapours that collect in the antarctic circle beyond the limits of Peru before they discharge their humidity. But, as a compensation for the want of rain, there is uniformly a very heavy fall of dew during the night; and the country is also intersected by rivers, streams, and torrents, by which, at intervals, strips of the long and dreary waste are redeemed from natural sterility. The insulated valleys thus formed constitute the whole habitable parts of Western or Lower Peru, as it is sometimes called; but they are situated from twenty to ninety miles apart. The banks of the water-courses are the parts which, by being laboriously irrigated, are rendered fruitful, and peopled in proportion to the supply of water. During the season when the snows of the Andes melt, the rivers swell to a prodigious extent, and can only be crossed by means of a balsa, which is a raft or frame-work fastened upon four bulls' hides sewed up, made air-tight, and filled with wind. A few of the large rivers reach the sea, but the smaller ones are exhausted in irrigating the cultivated patches, or are absorbed by the encompassing desert. "No stranger can travel from valley to valley," says Miller, "as the inhabited strips are inappropriately called, without a guide; for the only indication that the desert has been trodden before, is an occasional cluster of bones, the remains of beasts of burden that have perished. The sand is frequently raised into immense clouds by the wind, to the great annoyance of the traveller, who generally rides with his face muffled up." The habitable parts of Western Peru, therefore, are merely a series of oases in a great desert of sand, similar to those of Africa. It presents great inequalities of surface, and some of the sand-hills attain the elevation of mountains. But size is a relative term; and in the presence of the stupendous back-ground of the Andes, which lessens all neighbouring objects, they shrink into mere hills of diminutive size. The constant evaporation which is continually going on, as is evinced by the great nocturnal fall of dew, produces a haziness in the atmosphere, and the sun seldom appears with that brilliancy which it displays in the higher levels. Indeed, for six months of the year, a fog, which is considered as very beneficial, hangs over the country; and although, at the most, it attaches itself as a fine mist to woollen clothing, the Limanese call it aquaceros, a torrent. The heat is seldom so intense as to prevent the labourers from working in the open air, and the thermometer rarely rises to above seventy-five degrees. The medium height throughout the year, in which there is little variation, is about sixty-four degrees. In this district are produced most of the tropical plants. The plantain, banana, pine-apple, sugar-cane, vine, cocoa, olive, coffee, and cotton, as well as the most delicious fruits, some peculiar to the country, arrive at great perfection.

Peru of the Andes.

As we advance from the coast towards the Andes, vegetation becomes more luxuriant, for as the growth of plants depends upon the supply of water, that supply is greatest the nearer we approach to the sources of the streams. The range of the Andes nearest to the Pacific Ocean commences generally with hills of moderate elevation, but in some parts with bold, projecting, and abrupt precipices. The sides of these hills are covered with forests, rendered almost impenetrable by the numerous parasitical plants which twine around the lofty trees, and, whilst by their verdure they give beauty to the scenery, prevent the access of visitants until a path be cut out by severe labour. These forests, hundreds of leagues in extent, afford acacias, mangle trees, arborescent brooms, and ferns; aloes and other succulent plants; cedars, cotton or Cuba trees of gigantic magnitude, many kinds of ebony, and other useful woods, many species of palms, and the maria, a tree of enormous size, used in ship-building. The valleys between the hills afford most of the trees which are natives of the tropics; but few of them are well fitted for the purposes of building.

The district called Higher Peru, commencing at the termination of the sands on the shore, continues increasing gradually in height towards the east, until the ridge of the Andes or the Cordilleras is attained. The line of perpetual snow is about 14,000 feet above the level of the sea, and from that line upwards vegetation necessarily ceases; below it, the plants, by regular gradations, display the nature of the climate, and its adaptation to the various families of vegetables; and, in different parts, exhibit every species of production which can be found, from the dwarf plants of Lapland, to the odoriferous spices of Sumatra.

This portion of Peru contains the sources of those vast rivers which traverse the whole continent of South America, and are the greatest on the face of the earth. Here the Maranon commences its unrivalled course; and here rise its magnificent tributaries, the Ucayale, Huallaga, and others, which themselves are swelled by an innumerable multitude of streams, descending from the eastern ridges of the Andes, all being finally absorbed by the monarch of the waters. This mountainous region of Peru possesses large tracts of soil of great fertility, and a climate admirably adapted for raising food for man. The air is much purer and more salubrious here than on the coast, where its heat and humidity generate fevers. There is a great variety of climate in the Andes, as may easily be inferred from the character of the country, rising as it does from nearly the level of the sea to a height far above the line of perpetual refrigeration, and thus presenting on one and the same parallel of latitude the different climates of all the regions of the globe. The valleys and plateaus embosomed in these mountains, in spite of their vicinity to the region of eternal snow, enjoy a moderate climate, and are very fertile. These are eagerly sought as an abode, especially by the Indians; and by the productions here cultivated the inhabitants of the coast are almost entirely supported. The number of articles of culture might be still further increased, for many useful plants hitherto unknown might be naturalized, if care were taken to ascertain the locality, and the relative proportions of atmospheric heat which they require, previously to their being transplanted. In this mountainous district are situated the famous gold and silver mines of Peru, the source of its unrivalled wealth, and the cause of all the misery which it endured for three centuries of slavery and degradation. They are seated deep in the recesses of the Andes, and at great elevations, so that the climate is very cold, and alike unfavourable to vegetation and to the health of man. The celebrated mines of Pasco and Huancavelica are between 13,000 and 14,000 feet above the level of the sea.

Eastern Peru.

But by far the largest, most beautiful, and most valuable part of the Peruvian territory lies to the east of the Andes, commencing on the eastern declivity of the second chain, and stretching to the confines of Brazil. In this vast region a thousand sources of wealth still lie buried, for the greater part of it may be said to be yet unknown, and the riches which it contains are immense. "Here are plains traversed by lower hills," says Dr Poeppig, "covered with an ocean of foliage, vying in beauty with the climate of Chili, and far surpassing it in the abundance and luxuriance of its productions. To these join, within the extensive frontiers, those boundless plains, where gigantic rivers, which roll their broad waves through solitary forests, are the only means of communication between the widely-scattered dwellings of a very scanty population."[1] In a word, as far as we are acquainted with this region, it appears to rival the finest parts of Brazil in fertility, luxuriance, and variety of vegetation; and the world does not present us with any higher standard of comparison. The vast plains in which the declivities of the Andes terminate are called sometimes Pampas del Sacramento, or more usually Collona, or the Land of the Missions. This name they owe to the Jesuits, whose zeal for the conversion of the natives induced them to penetrate these trackless solitudes, and to gladden them with the tidings of great joy. They planted a number of settlements throughout this vast unviolated wilderness, and, by collecting in villages the rude inhabitants, attempted to civilize them, not only by instilling into their minds the doctrines of religion, but by teaching them such arts as their limited natural talents enabled them to acquire. Many of these missions still exist, and, by the good which they have done and are still doing, they in some degree atone for the injuries inflicted on Peru by its subjugators. The Indian tribes who inhabit the Pampas are too numerous to be specified individually. They are small and scattered, with as many various languages as there are tribes or divisions, and differing much from each other in the degree of civilization to which they have attained. Some of them are docile and cheerful; others are savage and warlike, and continually in a state of hostility with one another. The banks of the Huallaga, the Ucayale, and other great rivers, are the parts most thickly peopled by the Indian tribes. The Pampas are represented as being covered with trees and verdure, and yielding balsams, oils, gums, resins, and many valuable drugs, spices, and other rare productions. The trees are lofty, and form impenetrable forests, in which wander all the animals peculiar to the torrid climate of America.

---

[1] Poeppig's Travels in Chili, Peru, and on the river Amazons, in the years 1827–32; a valuable German work on South America.

Pan del Sacr en-to.

The following excellent account of a very interesting portion of this vast territory is by a recent explorer of these regions. "The Pampa del Sacramento was so called from its having been discovered by some of the newly converted Indians in 1726, on the day of the festival of Corpo de Dios. It comprises the greatest part of the land lying between the Huallaga, the Ucayale, the Maranon, and the Pachitea (an upper tributary of the Ucayale, which rises near Pasco); and it is remarked with apparent justice in the Viagero Universal, that the two continents of America do not contain another country so favourably situated or so fertile. It is about three hundred miles long from north to south, and from forty to about a hundred in breadth. Two of its boundary rivers, the Maranon and Ucayale, are at all times navigable for vessels of large burden, and the other two for boats and small craft. There are a great many streams which rise in the centre of the district, some of which fall into the Ucayale, and others into the Huallaga, most of which are navigable for canoes and flat-bottomed boats at all seasons; those which fall into the former of these rivers are the most considerable, viz. the Pachitea, the Aguaytia, the Cuxhiabatay, and the Santa Catalina. The northern part is much intersected by channels from the Huallaga to the Maranon, which afford great facilities for communication. This part of the Pampa appeared to be quite flat and thickly covered with trees, some of which were large, and the soil a red clay. The level extends as far south as Sarayacu, in the neighbourhood of which, and across the Huallaga, it rises into gentle hills. Farther southward we had no opportunity of seeing the country, except upon the banks of the Huallaga, which were generally level, but occasionally intersected by hills, which, indeed, near the Pongo, and from the Caracol, where we embarked on the river, to Juana del Rio, are entitled to the designation of mountains. The hills which are marked in Mr Arrowsmith's map of Peru and Bolivia, published in 1834, as the east branch of the Andes, are not deserving of the name of mountains. The productions of the Pampa, as we learned from Padre Plaza (the present missionary priest) are all indigenous, and in general spontaneously produced. The earth supplies vegetables sufficient for the consumption of the inhabitants; and the rivers furnish an inexhaustible store of delicious fish of various kinds. The beasts in the forest are the same as are to be found in all parts from the Huallaga to Para. By the Padre's account, however, they are not numerous, from the great destruction of them by the Indians, which is sometimes wanton. There is an almost endless variety of beautiful birds, many of which are excellent food. The vegetable kingdom, which has hitherto been unexplored by botanists, rivals in beauty and fragrance that of any other part of the world. The climate seems very much like that of the island of Madeira. During our stay at Sarayacu, we registered the thermometer three times a day, and its minimum and maximum were 75° and 85° of Fahrenheit, and the sun at this time passed over our zenith. Padre Plaza told us, that in the dry season, that is, in June, July, and August, the temperature is extremely even, and the heat by no means oppressive, as it is allayed by refreshing breezes, which generally blow in the contrary direction to the current of the river. In December, January, and February, fevers and agues sometimes make their appearance, but are rarely attended with fatal consequences, when the parties affected take proper care, which these people, however, are not apt to do."[1] This fine and fertile garden of nature is inhabited by ten distinct tribes of Indians, differing considerably from one another in their manners and habits.

The Spaniards, and even the Peruvians before them, made little progress to the east of the stupendous barrier of the Andes, which indeed must for ever prove a great natural disadvantage to the eastern provinces, in shutting them out, as it were, from communication with the western portion of Peru. And when to these obstacles we add the precipitous height of the eastern declivity of the mountain chain, the impracticable forests, the dangers to be apprehended from the barbarians which people them, the almost insufferable heats, the annoyance of the innumerable venomous insects and reptiles, and the many deep and impassable rivers; when these circumstances are considered, we may cease to wonder that the conquerors of Peru should have made small advances beyond the range of the Cordillera. The Gran-Chaco, or Great Desert; the countries between Paraguay and Chiquitos; those reaching from Moxos and Apolobamba to the rivers Amazons and Huallaga, and from the Apurus to the Ucayale, are regions almost wholly unknown to us. Wherever the interior has been penetrated, it has been by means of some of those mighty rivers which, descending from the Cordilleras, have forced, as it were, a natural outlet through the otherwise impassable and almost boundless forests below. It was not, however, from the coasts of Peru, and by proceeding in an easterly direction, that the Spaniards reached them. They were originally made known by adventurers from the south, who discovered them, after toiling up the long and arduous passage of the river Paraguay. The difficulties with which the nations to the eastward of the Andes have to contend in the transport of their productions across the Cordillera, of course add very greatly to the expense of these articles. Those of Chiquitos and Moxos are transported more than two hundred leagues to Lima, over a double range of the Andes; and if they are taken to Buenos Ayres the distance is tripled. Nothing but gold, silver, and precious stones can repay the enormous expense of transport on beasts of burden over such extensive tracts of country, beset with all but insurmountable natural obstacles. It is not surprising, therefore, that with such impediments before them, the natives should relinquish the idea of cultivating the soil for the purpose of exportation, and remain content with raising what is barely sufficient for the supply of their own daily wants. But an entirely new road to Peruvian commerce might be opened by means of the vast rivers which traverse the country.

---

[1] Journey from Lima to Para across the Andes, by Lieutenant Smyth and Mr F. Lowe, p. 200 et seq. 1836.

Amidst the various circumstances which distinguish Peru, there are some of the most calamitous and terrific description. The whole country is subject to the most violent convulsions of nature. Earthquakes are frequently felt in almost every part, and are sometimes accompanied with most extensive and fatal effects. The lofty chain of the Andes is a collection of volcanoes, some in constant activity, others occasionally ejecting inflammable substances; whilst there are many whose fires in the lapse of ages seem to have burned out. Electrical phenomena are frequent in the Andes of Peru, some of which are regarded with superstitious veneration by the Peruvian of the lower class. When he sees a silvery lustre glistening through the clouds at midnight from the summit of a lofty mountain, or a phosphorescent light shining in the wooded clefts of the lower Andes, he is immediately persuaded that there are either rich veins of gold or silver running along the surface, or that the buried treasures of the incas invite the bold adventurer to search for them, which he frequently does. Appalling visitations of thunder and lightning are not uncommon in all parts of Peru excepting the western coast.

Productions.

In enumerating the productions of this country, we shall commence with those of the Pampas, where by far the most valuable of them are to be found. We pass over the flora, which is unusually rich and extensive, and also plants of a humbler character; for, although interesting to the man of science, they would form but a dry catalogue of botanical names to the general reader. The vegetables which at present form articles of use or commerce are, coffee, sugar, rice, maize, capaiva, sarsaparilla, Peruvian bark, cotton, resin, cocoa, and gums, including copal and laurel wax, bees' wax, and a variety of oils. Of dye-stuffs there are, anatto, amarillo, cani, mahogany-bark, indigo, shambo, morado, ensena which resembles logwood, and others. In describing the qualities of some of these, and the quantities in which they are produced, Thadeus Häenke observes, "The cocoa of Apolobamba, of Moxos, of Yuracarees, and of all the woods which extend from thence to the shores of the Maranon, is infinitely superior to that of Guayaquil. The finest quality of carscarilla is only found on the eastern side of the Andes. Of the indigo there is no end; I can say the same of the cotton and the rice. The precious balsam of capaiva, the sarsaparilla, the gum-elastic, and the most fragrant species of vanilla, are all produced in extraordinary abundance in these regions. The mighty forests which line the shores of the rivers abound in the finest timber for all uses, especially for ship-building, and in trees distilling the most aromatic and medicinal gums. Amongst others there is a species of cinnamon, called by the natives the *canela de clova*, which only differs in the greater thickness of the bark and its darker colour, according to its age, from that found in the East Indies, and which is as fragrant as the spice from which it takes its name."[1] Lieutenant Smyth describes the woods as consisting of mahogany, cedar, asarquiro, nogal, almendra, huito, arabisa, chonta, spindo, and others. The fruits are the pine-apple, which attains an incredible size, the orange, chirimolla, lucuman, ciruellas, patillos, guayabas, figs, limes, citrons, papayas, melons, water-melons, lemons, granadas, granadillas, apples, avocater pears, olives, pomegranates, cherries, peaches, quinces, grapes in abundance, bananas, pepinos, plantains, guavas, peras, duraznos, strawberries, mulberries, and a number of others. There are a great variety of vegetables, including yucas, potatoes, sweet potatoes, onions, mountain-cabbage, beans, and so forth. The grains usually cultivated are wheat, barley, and maize. In some parts excellent tobacco is raised; and in others large quantities of sweetmeats, both dry and in syrup, are made from peaches, quinces, and grapes, the latter being much esteemed. Gourds attain an enormous size in some districts, and are converted into all kinds of household utensils required by the Indians, even into wash-tubs, from which circumstance some idea of the magnitude of the vegetable may be formed. Huanuco, a place situated at 6300 feet above the level of the sea, in a beautiful valley upon the eastern side of the Andes, and seventy-four miles from Lima, is celebrated for the productiveness of its soil. Here grow all sorts of vegetables, and grains and fruits, the latter being produced in greater perfection than in any other part of Peru. There is a fruit called chonta, from which the Indians prepare an intoxicating liquor; but the staple article made use of for producing the effects of wine, spirits, or opium, is coca; and as this remarkable plant is very extensively cultivated, and has now become an indispensable necessary of life amongst the Indians of the Andes, it merits some attention.

Coca

The coca (*Erythroxylon coca*, Lam.) is a bush from six to eight feet in height, somewhat resembling a black thorn in its numerous small white blossoms and the lively bright green of its leaves. The latter, which are gathered and carefully dried, form an article of brisk trade, and the use of them seems as old as the first knowledge of the history of Peru. It is a stimulant, which acts upon the nervous system in the same manner as opium, and unhappily the use or abuse of it has degenerated into a vice, or rather a disease, which appears to be incurable. "The Indians of America," says an able writer on this subject,[2] "especially those of the Peruvian Andes, notwithstanding the civilization which surrounds them, have a vague sense of their own incurable deficiency, and hence they are eager to relieve themselves, by violent excitements, from such melancholy feelings. This accounts not only for the use of coca, but also for the boundless love of spirituous liquors, which possesses scarcely any other people in the world in an equal degree. To the Peruvian the coca is the source of the highest gratification; for under its influence his usual melancholy leaves him, and his dull imagination presents him with images which he never enjoys in his usual state." Dr Poeppig draws a melancholy picture of the dreadful effects of this insinuating drug, which gives rise to many diseases apparently in some degree peculiar to those who use it. A person abandoned to the use of coca is under the dominion of a spell so malignant that no earthly power can dissolve it, and so fascinating that no prospect of danger will deter him from gratifying his propensity. As soon as the longing for this intoxication becomes irresistible, the coquero sculks for concealment into solitary darkness, or flies from the face of man into the depths of the wilderness, where he makes choice of a tree, beneath the shade of which he flings himself down to enjoy his coca. Unheeded he observes night closing upon him, doubly awful in the gloomy forest; and tempests of wind and rain, the fury of the hurricane which uproots the oldest trees, the terrible roll of the thunder, augmented a thousandfold by the multiplied reverberations of the Andes, or the presence of the ounce, abroad for his nightly prey, and growling at his feet, all are insufficient to appal the debauchee, or rouse him from his lethargy. In two days he generally returns, pale, trembling, his eyes sunk, the most fearful picture of unnatural indulgence which humanity ever presented. He who has once been seized with this passion, and is placed in a situation that favours its development, is considered as a lost man. Dr Poeppig informs us that there are many instances of young men of good families amongst the whites and Creoles, who, having obtained a relish for coca, were from that moment lost to the civilized world. Shunning society, they retreated into the most unfrequented parts of the wilderness, and there, degraded, and sunk into half savages, they fell victims to premature death, through the immoderate use of this intoxicating herb.

[2] Foreign Quarterly Review for April 1836.

The grapes are so abundant in some parts that large quantities of wine might be made for exportation; but no more is produced than is needed, and a little is even imported. Strong liquors, such as brandy and rum, are distilled; and oil is made from the olive. The various kinds of capsicums are cultivated with more attention and skill than almost any other plants, and, when dressed in various ways with garlic, form a most important article of food to the greater portion of the inhabitants. The celebrated Paraguay tea is likewise a very common beverage. Another liquor in universal use is chica, which, from having been found in the tombs of the aborigines, is proved to have been used by them prior to the conquest. The chica of the present day is of the consistence of milk, of a yellowish colour, and, when poured from one vessel into another, froths like beer. Its taste is generally acid, but when very good the acidity is scarcely perceptible. It is made by steeping Indian corn in water till it swells, after which it is dried and ground. The flour and bran are boiled in water, strained, and left to ferment four and twenty hours, when it is fit for use. Sugar is occasionally added; and with eggs it is sometimes made into flip.

The zoology of Peru has not received that attention which has been bestowed upon the vegetable kingdom by the distinguished travellers Humboldt and Bonpland. The three most celebrated animals of the Peruvian Andes are the lama, the vicugna, and the condor, an account of which is given in the article Bolivia. The demand for animal food is but small, and hence little attention has been paid to the breeding, and none to the fattening, of cattle. Neither cows nor sheep are numerous; those found in the country are the progeny of the breed brought originally from Europe. In the mountainous districts, between Huamanga and Cuzco, both butter and cheese are made; but in the lower country, oil is the universal substitute for the former. Pigs are bred in great numbers in the more elevated districts. The whole coast is well stored with fish of every kind. The natives of the Indian villages on the shore are very dexterous in catching them; and, with the addition of capsicum and garlic, they form the chief part of their subsistence.

Peru is proverbial for its richness in mines of gold and silver, especially the latter, although the former is proportionally plentiful. "Gold," says Thadeus Häenke, "and it is the finest in the world, is found there in such abundance, that I have no hesitation in saying there is scarcely a pass in the mountains where it is not to be discovered, although in some parts it may be of easier access than in others, and better known." The quantity of gold produced in Peru arises partly from some mines in the province of Tarma, and partly from washings established on the rapid mountain torrents. The latter, however, have in many instances been abandoned. The principal silver mines are situated in the Cerro de Pasco (see the article Pasco). There are also mines of quicksilver, which, however, are now exhausted, or nearly so.[1] Cobalt, antimony, and especially rock-salt, abound in Peru; but as these are, excepting the latter, found chiefly in the mountainous districts, the distance, and the want of roads, render their conveyance too expensive to enable them to be advantageously carried to any market of consumption. There are a few mines of copper and of lead, which, from the same causes, are worked on a very contracted scale. In the northern territory there are said to be mines of sulphur which remain unworked, and bituminous pitch is found in the same quarter. Dr Meyen[2] mentions that Tarapaca, in the department of Arequipa, has received from nature a peculiar present in its woodmines, which the inhabitants use as fuel in their saltpetre works, although probably there is not a single tree in all the surrounding country. This substance is not coal, but is stated to be dry timber, easily cleft, immense forests of which are buried under the sand of that plain. The trees all lie prostrate, with their tops towards the coast, and the timber is found exceedingly useful, burning with a flame as bright as that of common wood.

Antiquities.

Amongst the antiquities of Peru may be numbered Cuzco itself, and the ruins of other cities or towns, which have been much more recently discovered, and to which we have already alluded. There are also extensive remains of fortifications; and a great number of tumuli or sepulchral mounds are found widely scattered over the country. In these, relics of various kinds have been discovered, such as gold and silver ornaments, warlike weapons, and household utensils, comprising jars of earthenware, with figures upon them, which proves that the Indians were acquainted with pottery. Dr Poeppig informs us, that the mania of digging for treasures annually destroys in Peru many ancient and remarkable remains. Wherever the Peruvian beholds tumuli evidently raised by the hand of man, or an ancient building indicates the former abode of an exterminated people, he immediately suspects the existence of the guacas or caverns, which were filled by the incas at the time of the conquest with gold and precious stones, and forgotten at the premature death of these chieftains, who had buried their treasures from a sense of duty, and not chosen any persons as the depositaries of their secret. The work of demolition immediately commences; the abodes of the dead are rudely violated, and in their eagerness to find what alone to them is valuable, the Peruvians, and the Spaniards likewise, pay little attention to the preservation of the other interesting relics, but carelessly break them to pieces, and scatter them about. There will soon not be a tumulus left in the country. The most absurd fables have been invented and set afloat in connection with the favourite hypothesis of vast treasures remaining yet undiscovered. According to a tradition coeval with the conquest of the city of Cuzco, there is in a mountain lake in its vicinity a gold chain which went twice round the market-place, and of such large proportions that an Indian could with difficulty carry a single link of it.

Manufactures.

The manufactures of Peru are inconsiderable, and consist chiefly of those homely articles which are required by the poorer classes of the community. On the high land, where warm clothing is necessary, the want is chiefly supplied by a species of long-woolled baize, made from the fleeces of the aboriginal sheep, and in some instances from the wool of sheep of the European breed. In the valleys, and on the coast, where the heat forbids the use of woollens, cotton cloths are made, but of a very inferior texture. The Indians manufacture a variety of cotton fabrics, which are consumed in the country, such as counterpanes with raised figures. Straw-hats of a variety of colours, petates or mats, and segarreros, also form part of their manufactures; and they likewise execute a very fine filligree work of gold and silver. Goat-skins are made into good cordovan. Tanning, soap-making, distilling, saltpetre, and other manufactures, are also amongst the items of productive industry; but Peru looks to Europe for a great part of the necessaries as well as the luxuries of life. In dyeing the cloths, whether of woollen or cotton, the natives make use of plants which are scarcely known in Europe, or at least have not been applied to the same purpose. The dress of the Peruvians is very simple, consisting of a square cloth, with a hole in the centre, through which the head is thrust, and which falls before and behind so as to defend the whole body. The head is generally covered with a hat made of the straw of the maize, which is as large as, and serves the purpose of, an umbrella.

---

[1] For a particular account of the mines of Peru, the quantities which they have produced, and their actual condition, see the article Mines.

[2] Meyen, Voyage round the World, Berlin, 1835.

Commerce. The foreign trade of Peru is principally carried on with the united kingdom of Great Britain and Ireland, into which the following articles were imported during the year ending January 1836.[1]

Goods exported from Peru to Great Britain.—Pot and pearl ashes, 9 cwts.; Peruvian bark, 160,152 lbs.; untanned hides, 3526 cwts.; saltpetre and cubic nitre, 41,354 cwts.; undressed seal-skins, 2222; unrefined sugar, 5782 cwts.; cotton-wool, 105,661 lbs.; sheeps' wool, 908,626 lbs.; about four cwts. of molasses; and some other articles, including a considerable quantity of gold and silver specie.

Goods imported into Peru from Great Britain.—Cotton manufactures entered at value, L.403; wheat, meal, and flour, 833 cwts.; plain linens and diaper, 1282 pieces; quicksilver, 12,025 lbs.; foreign thrown silk, 1370 lbs.; silk manufactures of Europe, 4098 lbs., and of India, 415 pieces; spirits, viz. rum, gin, and brandy, in nearly equal quantities, 11,794 proof gallons; wines of all sorts, 16,529 gallons; ale and beer, nine tuns; tea, 134 lbs.; apparel, slops, and haberdashery, L.3312 of declared value; arms and ammunition, L.332 do.; brass and copper manufactures, L.806 do.; cotton manufactures, 9,886,075 yards, the declared value of which was L.283,007; hosiery, lace, and small wares, L.9873; cotton twist and yarn, L.380; earthenware of all sorts, L.4193; glass, L.5317; hardwares and cutlery, L.15,039; beaver and felt hats, L.475; iron and steel, wrought and unwrought, L.4174; leather, wrought and unwrought, 2481; saddlery and harness, L.145; linen manufactures, 685,250 yards, declared value, L.29,736; machinery and mill-work, L.808; painters' colours, L.569; plate, jewellery, &c. L.215; salt, 2000 bushels; silk manufactures, L.8758; soap and candles, 40,224 lbs.; stationery of all sorts, L.755; tin and pewter wares and tin plate, L.1946; woollen manufactures, L.63,559; woollen hosiery and small wares, L.1117; cinnamon, 918 lbs.; gum-arabic, 13 cwts.; and there were, besides, small quantities of cocoa-nuts, nutmegs, pepper, refined sugar, rhubarb, coffee, tin, butter and cheese, coals, culm and cinders, cordage, and so on. The total declared value of British and Irish produce and manufactures imported into Peru during the year 1835 was L.441,324. By comparison with former years this shows a decided increase of our trade with Peru. In 1827 it was L.228,466; in 1830, L.368,469; in 1832, L.275,610; in 1833, L.387,524; and in 1834, L.299,235. This shows remarkable fluctuations; but these must for the most part be attributed to the political agitations of the country.

The trade of the United States with Peru is next in importance to that of Great Britain, and it displays the same fluctuations, and likewise the same increase on a number of years. The exports from Peru into the United States during the year 1835 amounted to 1,118,278 dollars. During the previous year the amount was only 618,412 dollars. A considerable quantity of gold and silver specie is imported into the United States from Peru. The imports into Peru from the United States consist of flour in very considerable quantities, raw cotton, beef and pork, butter and lard, candles, soap, chairs, cider, gunpowder, turpentine, linseed oil, tobacco, wax, quicksilver, German linen, Russian sheetings, and steel. It will be seen that these articles are for the most part different from those imported into the country by Great Britain.

The trade of Peru with France is likewise considerable. The gold and silver specie, the bark, tin, skins, hides, and other productions of the former, being exchanged for the silks, brandy, wine, and other commodities of the former. With Spain likewise a trade of much the same nature is carried on. Quantities of specie and a few other articles are sent to Genoa, Canton, and other ports. From Paraguay large quantities of the Paraguay tea are introduced. It must be observed with regard to the trade of Peru, that a considerable quantity of the produce of the country is imported into Great Britain and other places at second-hand from Buenos Ayres and Valparaiso. Indeed, much of the foreign trade of Peru is carried on through the medium of Buenos Ayres.

Peru carries on some trade with Chili, and also with the states to the north of its own territory. Timber for the construction of ships and houses is brought from Guayaquil, and indigo from Mexico. Large quantities of wheat are imported from Chili; for although Peru might easily raise a sufficiency of all kinds of cerealia to supply its own consumption, it has never been able to do so. A few years ago a heavy duty was imposed on the wheat imported from Chili, with the view of encouraging its cultivation at home. But the Chilians became indignant, and reciprocated by imposing a duty of twelve dollars per quintal on the importation of Peruvian sugars. The Peruvian congress then proposed to admit into their ports all foreign vessels at reduced duties, on condition of not touching previously at any Chilian port. The two states thus view each other with a jealous eye in their commercial affairs, and also in other respects. The moneys, weights, and measures are the same as those of Spain.

The following is an abstract of the commercial treaty lately concluded between Great Britain and the Peruvio-Bolivian Confederation.[2] It is agreed that there shall be perpetual amity and freedom of commerce between Great Britain and these countries, complete protection and security to person and property being afforded; but that the coasting trade shall be confined to national vessels. That Peruvio-Bolivian vessels, in trading with Great Britain, shall enjoy the same privileges as the traders of the most favoured nation, duties and other charges being the same; and this stipulation is reciprocal. After the expiration of fifteen years, it is agreed that there shall be no distinction between Peruvio-Bolivian and British vessels in entering each other's ports. To avoid future misunderstanding, it is also agreed that, for fifteen years, any ship, the property of a citizen of the Peruvio-Bolivian Confederation, and of which the master and three fourths of the crew are such, shall be placed on the same footing as a national vessel, that is, a vessel built in the country; but after the period specified expires, the sovereign of Great Britain is to possess the right of restricting the privileges enjoyed by a ship of either country to such as are actually *built* in that country, taken in war, or condemned for trading in slaves. That the citizens and subjects of the contracting parties, in the territories of each other, shall be placed upon the same footing as the natives, with the privilege of exemption from all compulsory military services, exactions, or requisitions, and from forced loans. That liberty of conscience and freedom of religious exercises be enjoyed; and that the Peruvio-Bolivian Confederation shall co-operate with Great Britain for the total extinction of the slave-trade. There are some other stipulations in the treaty, but these, being of minor importance, do not require particular mention.

---

[1] Extracted from the parliamentary papers for the year 1836. The quantities are given in round numbers.

[2] Treaty of amity, commerce, and navigation between his Majesty William IV. and the Peruvio-Bolivian Confederation, signed at Lima, 5th June 1837. Parliamentary Papers for 1838.

Peru labours under disadvantages exceedingly unfavourable to its commerce. On the whole Pacific coast, for about two thousand miles, there are only three or four ports capable of admitting vessels of any size, viz. Callao, the port of Lima; Arica, a port of Arequipa, and a miserable place, although resorted to by trading vessels, for want of a better, it is presumed; and Islay, the new port or harbour of the city of Arequipa. It is supposed that the commerce will increase when the port of Arica is closed, which has been contemplated by government. Farther north is the port of Pisco, a small place, but enjoying some share of maritime commerce, although not a port of entry. From Callao to the confines of Colombia there does not appear to be one port worthy of the name, if we except Pacasmayo, the port of Truxillo, which is a wretched place, and Paita, the port of Piura. Add to this disadvantage that of the barrier of the Andes, which cuts off all communication, except at a great expense, between the richest part of the country and the coast where its native wealth might be readily exported. These are heavy drawbacks on all commercial industry; and, as the latter is an insurmountable difficulty, the Peruvian government must look to another quarter for an outlet for the produce of the country. This is to be found in the numerous large and navigable rivers which traverse the regions situated between the Andes and the Amazons, the great natural drain of all these territories. The advantages which Peru would derive from commercial intercourse with civilized nations are too great and too obvious to be overlooked by the government, if tranquillity were only permanently restored. But as long as these republics continue to tear each other to pieces, and exhaust their resources in fruitless warfare, little improvement in commerce or amelioration of their social condition is to be anticipated. In reference to the navigation of the Amazons and its affluents, it has been well observed by an able writer—"The time appears to be now arrived, when the solution of the question touching the course of the great rivers that empty themselves into the Amazons between the Huallaga and the Madeira may be expected. And we anticipate with confidence, that a question of so great importance in a commercial point of view, will not escape the notice of the patriotic government of Bolivia, and of its highly gifted president Santa Cruz; and that, ere long, the productions of the rich provinces of Apolobamba, Moxos, and of the other countries situated on the eastern declivity of the Andes, will find their way to European markets by the less circuitous route of the Amazon and its confluents."[1]

Revenue, finances, and war-like force.

It is nearly impossible to obtain precise information as to the amount of the present revenues of Peru. Under the colonial government of Spain, the revenues of the crown amounted, *communibus annis*, to about 6,000,000 of dollars, and the expenditure to about 3,200,000; the balance being annually remitted to the parent state. The present revenue has been estimated at L.1,250,000, the expenditure at a little less than that sum, and the national debt at about L.6,000,000. In the year 1832, it was agreed to between the states of Peru and Bolivia, that for the future the former should be obliged to maintain a military force of 3000, and the latter of 2000 men, and that neither power should be at liberty to augment its army without the consent of the other. The naval force is very small, consisting of one frigate, two corvettes, and two galliots; but this must be considered as the peace establishment. When the country is at war, it will be necessary to increase the military force considerably.

Religion, education, and morals.

According to the constitution of 1828, the religion of the republic is the Roman Catholic and apostolic. "The nation permits it by all the means that conform to the spirit of the evangelist, and will not permit the exercise of any other." It may be mentioned, that a similar article is found in the Chilian constitution of May 1833. The question of religious toleration gave rise to very animated discussions in both countries, and called forth all the powers of the author of Cartas Peruanas, in support of the exclusive exercise of the Catholic religion, and the supremacy of the pope. The work here mentioned was an examination of the evidences of Christianity, and was published to neutralize the bad effects of the infidel and irreligious books which some interested persons had disseminated throughout the country during the revolutionary agitations. Education is said to be at a low ebb. There is a university at Lima, which in 1831 had fifty-five students. This institution is the most ancient and the most celebrated in all South America. There are a number of colleges, and a national library, which is one of the richest in the New World. Ten or twelve journals are published in Lima; indeed, if this city were to be taken as a fair criterion by which to judge of the state of literature and learning in Peru, we might be led to form a very high estimate of it, for it concentrates nearly the whole in itself. But, since the revolution, extensive arrangements have been made for the general diffusion of knowledge amongst the people.

South Peru is divided into the departments and provinces specified in the following table.

Departments, with their Population in 1795.	Provinces.	Chief Towns.
Arequipa, 136,812.	Arica, Callyoma, Camana, Cercado, Condesuyos, Moquegua, and Tarapaca.	Arequipa, Arica, Camana, Huantagaya, Moquegua, and Tackna.
Ayacucho, 159,608.	Andahuaylas, Cangallo, Castrovireyna, Huamanga, Huancavelica, Huanta, Lucanas, Parinacochas, and Tayacaja.	Huamanga, Ayacucho, Jauja, Huancavelica, Lucanas, and Ocopa.
Cuzco, 216,382.	Abancay, Ayamaraes, Calca, Cercado, Cotabambas, Chumbivilcas, Paruro, Paucartambo, Quispicanchi, Tinta, and Urubamba.	Cuzco, Albancay, Tinta, and Urubamba.
Puno, 156,000.	Azangaro, Carabaya, Chucuito, Huancane, and Lampa.	Puno, Chiquito, Caillomas, and Lampa.

North Peru is divided in the same manner. The new department called the Pampas has been formed out of the territories of Junin and Truxillo; but as its extent and divisions have not yet been described in any work on Peru, we are under the necessity of giving the local geography of this republic as it stood in 1835–1836.

---

[1] Journal of the Geographical Society, vol. vi. p. 186, 1836.

Departments, with their Population in 1795.	Provinces.	Chief Towns.
Lima, 149,112.	Canta, Cañete, Chancay, Huarochiri, Ica, Santa, and Yauyos.	Lima, Callao, Cañete, Chancay, Huaco, Huauro, Ica, Pisco, and Patibilca.
Libertad or Truxillo, 230,970.	Cajamarca, Chachapoyas, Chota, Huamachuco, Jaen, Lambayeque, Maynas, Patas, Piura, and Truxillo.	Truxillo, Caxamarca, Casabamba, San Juan de la Frontera, Eten, Lambayeque, Moyobamba, Micuipampa, Payta, Piura, and Sechura.
Junin, 200,839.	Cajatambo, Conchucos, Huaylas, Huamalies, Huanuco, Hauri, Jauja, and Pasco.	Huanuco, Banos, Huaras, Junin, and Pasco.

The total population, as stated above, is 1,249,723; but it is now (1838) estimated at 1,700,000. The inhabitants of Peru consist of three original castes; Spaniards, Indians, and negroes. The secondary species arising from these three are, the mulatto, from the Spaniard and negro; the quarteroon, from the mulatto and Spaniard; and the mestizo, from the Spaniard and Indian. The other subdivisions are as numerous as the possible combinations of the primitive castes. The Indians or native Peruvians are still the most numerous class throughout the country. They present nothing of the fierce and untamed character of the Caribbs or Canadian Indians, but are timid, reserved, and of a melancholy temperament. Much of their apathy and insensibility is unquestionably natural to them, but it has been deepened and rendered more inveterate and habitual by ages of oppression. They are sunk in gross ignorance; but that they are incapable of being roused from their lethargy, and taught the arts of peace and civilization, is a gratuitous absurdity, which several of them have triumphantly refuted by making a distinguished appearance in the pulpit and at the bar. The manufacture of beautiful fabrics is quite common amongst them, and many of the tribes are industrious agriculturists. They have been converted to Christianity; and they have wiped off the reproach of cowardice by their achievements during the war of independence, in which they generally took the part of the royalists. Yet they cherish a deep and mournful impression of the days of the incas; and in all the remote districts of the country the death of the last of the race is annually celebrated by a sort of rude tragedy, accompanied by plaintive and melting strains of music. The mixed races are more numerous than the pure Spaniards, although less so than the native Peruvians. According to Mr Stevenson, the mestizo is strong and swarthy, with very little beard, laborious, and well disposed; the mulatto is less robust, but acute, talkative, imaginative, and fond of dress and parade. In a public disputation at the university, a mulatto in the gallery will often help the embarrassed student out with his syllogism. The zambo, or mulatto and negro, is violent, morose, and stubborn, prone to many vices, and guilty of more robberies and murders than any of the other classes, excepting only the Chinos or negro-Indians, who are said to be the very worst mixed breed in existence; they are ugly, lazy, stupid, and cruel. (R. R. R.)

PERUGIA, a delegation or province of the States of the Church, in Italy, and a part of the ancient Umbria. It is 1793 square miles in extent, and contains seven cities, nineteen market-towns, with numerous villages, and 181,540 inhabitants. It includes a large portion of the Apennines, and is therefore very hilly; but that part through which the Tiber passes is a succession of beautiful and fertile valleys, producing abundance of corn, pulse, fruit, cattle, silk, oil, and wine, besides much honey and wax. The capital is a city of the same name, situated in a rich valley between the Tiber and Lago Perugia, and surrounded by walls and ditches, but not deemed capable of being defended. It is the see of an archbishop, and, besides the cathedral, adorned with the pencil of Peter Perugiano and of Raffaele, contains forty-five parish churches, twenty-four monasteries, twenty-five nunneries, and several charitable institutions; besides a university, which has of late years greatly declined. There are several learned societies, a fine theatre, and some pleasing promenades. In Perugia, though an ancient city, few remains of antiquity are to be seen. The most remarkable of those that remain are the gate of the Grimana Palace, called the arch of Augustus, and the temple of Mars, at the gate of St Angelo. The population is doubtful, some authors stating it at 68,000, whilst Balbi, the latest authority, estimates it only at 30,000. A considerable trade in the raw productions of the fertile soil which surrounds the city centres here; and there are manufactures of silks and velvets, of woollen goods, hats, leather, tartaric acid, brandy, and liqueurs. Many of the private houses are adorned with valuable paintings of the ancient masters. Long. 12. 16. 53. E. Lat. 43. 6. 46. N.

PERUVIANA, a general name sometimes applied to the vast peninsula of South America, extending from the Isthmus of Panama to Cape Horn.

PERUWELS, a market-town of Belgium, in the province of West Flanders, and circle of Tournay. It is situated on the frontier towards France, and contains 5650 inhabitants, employed in making linen, in breweries, and distilleries.

PERWUTTUN, a village on the southern shore of the river Krishna, in a wild tract of almost uninhabited country. Here is a remarkable pagoda, wherein there is an idol, which is shown by the reflected light of a brass speculum, and can only be seen as the flashes fall on it. The pagodas, choultries, and courts, are enclosed by a wall which is covered with a great variety of sculpture. It is 118 miles south from Hyderabad. Long. 78. 40. E. Lat. 15. 57. N.

PESANO, a city of the province of Saluzzo, in the kingdom of Sardinia, in Italy. It is situated on the river Po, and contains 720 houses, with 4600 inhabitants.

PESARO, a city of the pontifical dominions, in Italy, in the delegation of Urbino cum Pesaro. It stands on the river Foglia, at its embouchure, and is surrounded with walls. It is the see of a bishop, and has a cathedral and seven parish churches, with eight monasteries and four nunneries, which have also churches, some of them decorated with paintings from the hands of the best masters. The houses are good, the streets broad; and there is a remarkably fine market-place, with a marble fountain, and a statue of Urban VIII. It contains 13,580 inhabitants, who are occupied in various branches of the silk trade, and in commerce in the raw productions of the vicinity, which are shipped from its small but secure harbour. Long. 12. 48. 16. E. Lat. 45. 51. 1. N.

PESCIA, a city of the duchy of Tuscany, in Italy, the capital of a district, in the province of Florence, of its own name. It is situated on the river Pescia, is the see of a bishop, and has a cathedral and two other churches, with

4200 inhabitants, who subsist chiefly by spinning and weaving silk, and making paper and pottery wares.

PESCINA, a city of Italy, in the province of Principato Ulteriore II. of the kingdom of Naples. It stands on the north-eastern side of the Lake of Cellano, is the see of a bishop, has a cathedral, with several other churches and monasteries, and contains 4500 inhabitants.

PESHAWUR, or PEISHARE, a district and very ancient city of Afghanistan, in the province of Caubul, intersected by the Caubul River, and surrounded on all sides by a mountainous range, by which it is sheltered from the cold winds, and rendered very hot during summer. It is well watered by innumerable streams flowing down the mountains, which are always covered with verdure, produces all sorts of garden-fruits, especially melons, and, with the exception of Cashmere, is considered as the finest province within Afghanistan. It is extremely populous, containing, within a circumference of thirty-five miles, 300,000 inhabitants. The city of Peshawur is large, being upwards of five miles in circumference. The houses are generally built of unburnt bricks in wooden frames, and are mostly three stories in height. The town is intersected by two or three brooks, which run into the Caubul River, and are crossed by bridges. The streets are narrow, but paved, and have a kennel in the middle. The Caubul passes to the north of the city; and the town is adorned with numerous mosques and other edifices, which scarcely merit any particular notice, if we except a caravanserai, and the citadel, which stands on a hill north of the town. This citadel, which is not a place of strength, contains some fine halls, and commands an extensive prospect of the surrounding country, and is adorned with spacious gardens. Few of the houses of the nobility are of any note, but there are some splendid palaces belonging to the king. The inhabitants of this city consist of tribes from all quarters of the East; but the common languages are the Pashtoo and the Hindustanee. The Hazarees, descended from a tribe of Tartars, are the most conspicuous tribe in this city, and still exhibit in their broad faces all the marks of the Tartar physiognomy. Peshawur is an ancient city, and is often mentioned in the histories of the tenth century. In the sixteenth century the city was much improved by Akbar, who, seeing the aversion of the Afghans to commerce and industry, encouraged a number of settlers from the Punjab; and it became a great commercial mart for the trade carried on between Persia, Tartary, and India. It is the residence of many wealthy merchants, especially shawl-dealers; and the markets are abundantly supplied with provisions. This city was visited in 1809 by the Honourable Mountstuart Elphinstone, who was sent as ambassador by the East India Company, and had an audience of Shah Sujah, the Afghan king, who was shortly afterwards defeated by his brother Shah Mahmoud, and obliged to fly. The country has ever since continued the scene of civil war. Long. 70. 37. E. Lat. 33. 32. N.

PEST, or PESTH, a city of the Austrian kingdom of Hungary, the capital of a circle, extending over 4202 square miles, and which comprehends two cities, twenty market-towns, and 319 villages, with 380,000 inhabitants. The city is situated on the left bank of the Danube, opposite to Buda, with which it is connected by a bridge of boats. The town has no walls nor gates, and is defended by a citadel. It is the trading portion of the Hungarian metropolis, and abounds in manufactures of various kinds, though mostly on a small scale. It has a university and several other institutions for education. It contains 3400 houses, and about 60,000 inhabitants. The vicinity is fertile, and produces much good wine. In the early part of 1838, Pest suffered severely from an inundation of the Danube, by which many houses were destroyed, and a great number of individuals lost their lives. Judging from the accounts which have been published, the desolation occasioned by this sudden and resistless outburst of the river must have been truly terrific, and many years will probably elapse before the injury done by the flood can be fully repaired. Long. 25. 57. 12. E. Lat. 47. 31. 40. N.

PETALISM, a mode of deciding on the guilt of citizens, similar to the Athenian ostracism. It was introduced into Syracuse about the year before Christ 460, to restrain the tyranny of the richer citizens, who about that time aimed at the supreme power. To prevent the evils daily arising from this source, and to bring down the aspiring minds of the wealthy citizens, the Syracusans passed a law not unlike that of the Athenian ostracism; for as at Athens every citizen was required to write on a shell the name of the person whom he conceived to be the most likely, on account of his wealth and adherents, to aspire to the crown, so at Syracuse the people were entitled to write on a leaf the names of such as they apprehended powerful enough to usurp the sovereignty. When the leaves were counted, he who had the most suffrages against him was, without any further inquiry, banished for five years. This new method of impairing the consequence and weakening the interest of the overgrown citizens was called *petalism*, from the Greek word πεταλον, which signifies a leaf. But the law in question was attended with many evils; for those who were most capable of governing the commonwealth were banished, and the administration of public affairs was committed to the meanest of the people. Nay, many of the chief citizens, who were able to render their country great service, apprehensive of falling under the penalties of this law, withdrew from the city, and lived privately in the country, not concerning themselves with public affairs; so that all the employments being filled by men of no merit or experience, the republic was reduced to the brink of ruin, and ready to fall into a state of anarchy and confusion. The law of petalism was therefore, on more mature deliberation, repealed soon after it had been first enacted; and the reins of government were again committed to the hands of men who knew how to manage them.

PETALNAIG, a town of Southern Hindustan, in the province of Tinnevelly, a hundred miles north-east from Cape Comorin. Long. 78. 15. E. Lat. 9. 13. N.

PETAREE, a large village of Hindustan, in the province of Malwah, forty-eight miles north-east from Bilsah.

PETAU, DENIS, or DIONYSIUS PETAVIUS, a French Jesuit of great erudition, was born at Orleans in the year 1583. His father, who was a man of learning, observing in his son strong parts and an excellent genius for letters, took every means in his power to improve them. He used to tell his son, that he ought to qualify himself so as to be able to attack and confound the giant of the *Allophylæ;* meaning Joseph Scaliger, whose abilities and learning were allowed to have done much service to the Reformed. Young Petavius seems to have entered readily into his father's views; for he studied most intensely, and afterwards levelled much of his erudition against Scaliger. To the study of the belles lettres he joined that of the mathematics; and afterwards applied himself to a course of philosophy, which he commenced in the college of Orleans, and finished at Paris. He subsequently maintained theses in Greek, which was as familiar to him as Latin; and the Latin, it is said, he understood better than he did his vernacular language. When he was pretty well advanced in his studies, he had free access to the king's library, which he often visited on account of the Latin and Greek manuscripts. Amongst other advantages which attended his literary pursuits, may be reckoned the friendship of Isaac Casaubon, whom Henry IV. called to Paris in 1600. It was at Casaubon's instigation that Petavius, though then very young, undertook an edition of the works of Synesius, in which he corrected the Greek from the manuscripts, translated what yet remained to be translated into Latin, and wrote notes upon the whole.

He was only nineteen years of age when he was made professor of philosophy in the university of Bourges; and he spent the two following years in studying the ancient philosophers and mathematicians. In 1604, when Morel, professor of Greek at Paris, published the works of St Chrysostom, some part of Petavius's labours on Synesius were added to them; and from the title we learn, that he then took the name of *Pætus*, which he afterwards changed into *Petavius*. His own edition of the works of Synesius did not appear till the year 1612.

He entered into the society of the Jesuits in 1605, and did great credit to it by his extensive and profound erudition. He became a zealous advocate of the Church of Rome; and there was no way of serving it more agreeable to him than that of criticising and assailing its adversaries. He was very bitter against Scaliger; nor did he even spare his friend Casaubon whenever the latter came in his way. Petavius excelled particularly in chronology; the learned world in general being indebted to him for some exact and nice disquisitions on this subject. His principal work, which is entitled *Rationarium Temporum*, is an abridgment of universal history, from the earliest times till the year 1632, arranged in chronological order, with references to proper authorities; and it was improved by Perizonius and others, who made several additions to it after his death. This eminent father, after a very laborious life, died at Paris about the close of the year 1652, aged sixty-nine.

PETCHELEE, a considerable and extensive province of China, in which Peking, the capital, is situated. Being one of the northerly provinces of China, its climate is cold, and the winter is severe, all the rivers being frozen during four months in the year, from November to March. It is in general of a sandy soil; a great part of it is a dead flat, and the sea-coast is bordered with extensive marshes. To the north the country is elevated, and rises into that range of lofty mountains along which the great wall is conducted. The country is not favourable for the production of rice; but it is well fitted for wheat, barley, and the other grains of the temperate climates. The principal river is the Peiho, which rises within the Tartar frontier, and, after passing Peking, discharges itself into the Yellow Sea, or Gulf of Petchelee. By means of this sea a considerable trade is carried on with Corea and Japan. But this province is chiefly indebted for its prosperity to the communications established between its rivers and the Imperial Canal, which affords a navigable communication across the whole empire. The population is estimated at 38,000,000.

PETER (originally *Simeon* or *Simon*, שמעון, called also, by a rendering of the Greek Πετρος into the corresponding word in the Aramaic dialect spoken in Palestine in the days of our Lord, *Cephas*, כיפא, John, i. 42), one of the twelve apostles, and author of two epistles in the inspired canon. He was a native of Bethsaida in Galilee, and was the son of a certain Jonas, or John, whence he is named on one occasion in the gospel history Simon Barjona, that is, son of Jona (Matt. xvi. 17). Along with his brother Andrew, he followed the occupation of a fisherman on the Sea of Galilee. It is probable that before they became known to Christ they were both disciples of John the Baptist. That Andrew was so, we are expressly informed by the evangelist John; and as his brother seems to have been much of the same mind with him on religious matters, it is extremely likely that he was so likewise. Their becoming known to Christ was owing to John's pointing him out on the day after his baptism to Andrew and another disciple (probably the evangelist John), as "the Lamb of God," on which they immediately followed Christ, and spent some time in receiving his instructions. Shortly after this, Andrew finding Simon, carried him to Christ, who, on receiving him as his disciple, bestowed upon him that surname by which he has since that time been most commonly designated: "When Jesus beheld him he said, thou art Simon the son of Jona; thou shalt be called Cephas, which is by interpretation a stone (πετρος)." After this interview the two brothers seem to have returned to their usual occupation for a season, as we have an account in Matthew (iv. 18–20), of their being summoned from that occupation by Christ on a subsequent occasion, posterior to his temptation in the wilderness, and to the commencement of his public ministry as a religious teacher. From this time forward they were his devoted and admiring followers. In the course of the evangelical history several anecdotes of Peter are incidentally recorded, for the purpose, doubtless, principally of illustrating the character and teaching of our Lord, but which tend also to throw light upon the history and character of his attached disciple. Such are the accounts furnished by the evangelists of his walking upon the agitated waters of the Sea of Galilee to meet his master (Matthew, xiv. 22, ff.; Mark, vi. 45, ff.); of his bold and intelligent avowals of the undoubted Messiahship of Jesus, notwithstanding the difficulties which he, along with the rest of the disciples, felt in reconciling what they saw in him with what they had fondly expected the Christ to be (Matthew, xvi. 13–20); of his rash but affectionate rebuke of his Lord for speaking of suffering and death as in prospect for him, and as forming a necessary part of his mediatorial work (Matthew, xvi. 21–23); of his conduct in first rejecting, with an earnestness bordering on horror, the offer of Christ to wash his feet, and then, when the symbolical nature of that act had been explained to him, his over-ardent zeal that not his feet only, but also his hands and his head, might be washed (John, xiii. 4, ff.); of his bold and somewhat vaunting avowal of attachment to his Master, and his determination never to forsake him, followed by his disgraceful denial of Jesus in the hour of trial (John, xiii. 36, 37; Mark, xiv. 29, &c.); of his deep and poignant contrition for this sin (Matthew, xiv. 72); and of his Lord's ample forgiveness of his offence, after he had received from him a profession of attachment as strong and as frequently repeated as his former denial of him (John, xxi. 15–18). From these notices it is easy to gather a tolerably correct conception of the predominating features of the apostle's character up to this period. He seems to have been a man of undoubted piety, of ardent attachment to his Master, and of great zeal for what he deemed his Master's honour, but at the same time with a mind rather quick than accurate in its apprehensions, and with feelings rather hasty in their impulse than determined and continuous in their exercise. Hence his readiness in avowing his opinions, and his rashness in forming them; and hence also the tendency which beset his honest openness to degenerate into bravado, and his determinations of valour to evaporate into cowardice at appalling forms of danger. His fall, however, and his subsequent restoration, connected as these were with the mysterious events of his Master's crucifixion and resurrection, and with the new light which had by them been cast around his character and work, produced a powerful change for the better upon the apostle's mind. From this time forward he comes before us under a new aspect. A sober dignity and firmness of purpose have displaced his former hasty zeal; sagacity and prudence characterize his conduct; and whilst his love to his Master shows no symptom of abatement, it displays itself rather in active labour and much-enduring patience in his service, than in loud protestations or extravagant exhibitions of attachment. In the subsequent Scripture history he is presented to us as the courageous herald of the kingdom of Christ, by whose mouth the first public declaration of salvation through the crucified Jesus was made to the people; by whose advice and counsel the early churches were planted and governed; and by whom the prejudices of Judaism were first fairly surmounted, and the gospel preached in all its universal freeness to the Gentile world.

The Acts of the Apostles contain recitals of many interesting incidents which befell him whilst engaged in those efforts. Of these, the chief are his imprisonment and trial before the Sanhedrim, for preaching Christ, and his bold avowal of his determination to persist in that work (Acts, iv. 1–22); his miraculously inflicting the punishment of death on the infatuated couple who had dared to try an experiment upon the omniscience of the Holy Ghost (v. 1–11); his visit to Samaria, and rebuke of Simon Magus, who deemed that the miracles of the apostle were the work of some deep magic spell of which he had not yet become possessed, and which consequently he was desirous of purchasing from Peter (viii. 14–24); the vision by which he was taught that the ancient ritual distinctions between clean and unclean had been abolished, and thereby prepared to attend on the summons of Cornelius, to whom he preached the gospel (x. 1–48); his apprehension by Herod Agrippa, and his deliverance by the interposition of an angel, who opened for him the doors of his prison, and set him free (xii. 3–19); and his address to the council at Jerusalem, on the occasion of a request for advice and direction being sent to the church there by the church in Antioch, in which he advocated the exemption of Gentile converts from the ceremonial institutes of the law of Moses (xv. 6–11). In all these incidents we trace the evidences of his mind having undergone an entire change, both as to its views of truth and impressions of duty, from what is displayed by the earlier events of his history. On one occasion only do we detect something of his former weakness, and that strangely enough in regard to a matter in which he had been the first of the apostles to perceive, and the first to recommend and follow, a correct course of procedure. The occasion referred to was his withdrawing, through dread of the censures of his Jewish brethren, from the Gentiles at Antioch, after having lived in free and friendly intercourse with them, and his timidly dissembling his convictions as to the religious equality of Jew and Gentile. For this Paul withstood him to the face, and rebuked him sharply, because of the injury which his conduct was calculated to produce to the cause of Christianity. With this single exception, however, his conduct seems to have been in full accordance with the name which his Master had prophetically bestowed on him when he called him Simon the Rock, and with the position which Paul himself assigns to him, at the very time that he recounts his temporary dereliction, as one of the "Pillars of the Church."[1]

Thus far we are enabled, from the inspired documents, to trace the history of this apostle; but for what remains we must be indebted to evidence of a less explicit and certain character. The testimony of several of the ecclesiastical writers, corroborated by the phraseology employed by the apostle himself in the salutation of his first epistle, makes it highly probable that at some period of his official life he performed an extensive missionary tour throughout those districts, to the converts in which his epistles were addressed. "It appears," says Origen, "that Peter preached to the Jews in the dispersion, in Pontus, Galatia, Bithynia, Cappadocia, and Asia."[2] A less certain tradition reports the apostle as having towards the close of his life visited Rome, become bishop of the church in that city, and suffered martyrdom in the persecution raised against the Christians by Nero. The importance of these points in connection with the claims urged by the Catholics on behalf of the supremacy of the pope, has led to a careful and sifting examination of the accuracy of this tradition; the result of which seems to be, that whilst it is admitted as certain that Peter suffered martyrdom, in all probability by crucifixion,[3] and as probable that this took place at Rome, it has, nevertheless, been made pretty clear that he never was for any length of time resident in that city, and morally certain that he never was bishop of the church there.[4] By some an attempt has been made to obtain the support of the apostle's own testimony in favour of his having at one period resided at Rome, by interpreting the words, "the church that is at *Babylon*," the salutations of which he sends to those to whom he wrote his first epistle, as applying to the church at *Rome*; an attempt which Dr Campbell justly stigmatizes as "poor, not to call it ridiculous." Even if we admit that at the time when this epistle was written it was understood amongst the Christians that Babylon was the prophetical name for Rome, an admission, however, which is entirely unsupported by evidence, it would remain unexplained why the apostle, in such a mere matter-of-fact affair as the communication of the friendly salutations of one church to another, should have employed the obscure and symbolical language of prophecy, when his meaning could have been so much more distinctly conveyed by a simple statement. This would be the more inexplicable, that the style of Peter is remarkably plain and perspicuous throughout the entire epistle. It seems much more consistent, therefore, with rational principles of interpretation, to understand the statement literally of Babylon in Egypt, in which city, as we learn from Josephus, there was a great multitude of Jews (ἐνθα ϰαι πληθος ἠν Ἰουδαιων, *Ant. Jud.* l. xv. c. ii. sect. 2; see also c. iii. sect. 1), and to which, consequently, it is almost certain, that at some period of his life, "the apostle of the circumcision" (Gal. ii. 8) must have paid a visit.

The assertion that St Peter was bishop of Rome is connected with another by which the claims of the papacy are sought to be established, namely, that to him was conceded a right of supremacy over the other apostles. In support of this, an appeal is made to those passages in the gospels, where declarations supposed to imply the bestowal of peculiar honour and distinction on Peter are recorded as having been addressed to him by our Lord. The most important of these are, "Thou art Peter, and on this rock will I build my church" (Matt. xvi. 18); and, "Unto thee will I give the keys of the kingdom of heaven," &c. (Matt. xvi. 19). At first sight these passages would seem to bear out the assumption founded on them; but upon a more careful investigation it will be seen that this is rather in appearance than in reality. The force of both is greatly impaired for the purpose for which Catholics produce them, by the circumstance, that whatever of power or authority they may be supposed to confer upon Peter, must be regarded as shared by him with the other apostles, inasmuch as to them also are ascribed in other passages the same qualities and powers which are promised to Peter in those under consideration. If by the former of these passages we are to understand that the church is built upon Peter, the Apostle Paul informs us that it is not in him *alone* that it is built, but upon *all* the apostles (Ephes. ii. 20); and in the book of Revelation we are told, that on the twelve foundations of the New Jerusalem (the Christian church), are inscribed

---

[1] Gal. ii. 9–14. The circumstance of Peter's having submitted to a rebuke from Paul is so fatal to the pretensions which have been urged in favour of his supremacy over the other apostles, that from a very early age attempts have been made to set aside its force, by the hypothesis that it is not of Peter the apostle, but of another person of the same name, that Paul speaks in the passage referred to; *Conf.* Euseb. *H. E.* i. 13. This hypothesis, however, is so plainly contradicted by the words of Paul, who explicitly ascribes apostleship to the Peter of whom he writes, that it is astonishing how it could have been admitted even by the most blinded zealot. See ver. 8, 9.

[4] See Barrow's Treatise on the Pope's Supremacy; Works by Hughes, vol. vii. p. 207, ff.; Campbell's Lectures on Eccl. Hist. lect. xii.; Neander's *Geschichte der Pflanzung und Leitung der Christ. Kirche*, bd. ii. s. 311–15; Winer's *Biblisches Realwörterbuch in Petrus*, &c.

St Peter.

"the names of the *twelve apostles of the Lamb*" (ch. xxi. 14). As for the declaration in the latter of these passages, it was in all its essential parts repeated by our Lord to the other disciples immediately before his passion, as announcing a privilege which, as his apostles, they were to possess in common (Matt. xviii. 18; John, xx. 23). It is, moreover, uncertain in what sense our Lord used the language in question. In both cases his words are metaphorical; and nothing can be more unsafe than to build a theological dogma upon language of which the meaning is not clear, and to which, from the earliest ages, different interpretations have been affixed. And, finally, even granting the correctness of that interpretation which Catholics put upon these verses, it will not bear out the conclusion they would deduce from them, inasmuch as the judicial supremacy of Peter over the other apostles does not necessarily follow from his possessing authority over the church. On the other side it is certain, that there is no instance on record of the apostle's having ever claimed or exercised this supposed power; but, on the contrary, he is oftener than once represented as submitting to an exercise of power upon the part of others, as when, for instance, he went forth as a messenger from the apostles assembled in Jerusalem to the Christians in Samaria (Acts, viii. 14), and when he received a rebuke from St Paul, as already noticed. Whilst, however, it is pretty well established that Peter enjoyed no judicial supremacy over the other apostles, it would, perhaps, be going too far to affirm that no dignity or primacy whatsoever was conceded to him on the part of his brethren. His superiority in point of age, his distinguished personal excellence, his reputation and success as a teacher of Christianity, and the prominent part which he had ever taken in his Master's affairs, both before his death and after his ascension, furnished sufficient grounds for his being raised to a position of respect and of moral influence in the church and amongst his brother apostles. To this some countenance is given by the circumstances that he is called "the first," πρωτος, by Matthew (ch. x. 2), and that apparently not merely as a numerical, but as an honorary distinction; that when the apostles are mentioned as a body, it is frequently by the phrase, "Peter and the eleven," or, "Peter and the rest of the apostles," or something similar; and that when Paul went up to Jerusalem by divine revelation, it was to Peter particularly that the visit was paid. These circumstances, taken in connection with the prevalent voice of Christian antiquity, would seem to authorize the opinion that Peter occupied some such position as that of προεστως, or president in the apostolical college, but without any power or authority of a personal kind over his brother apostles.[1]

The extant writings of the apostle Peter are confined to two brief epistles, of which the former has been universally admitted as genuine, whilst the latter has by many been rejected as spurious. The grounds of this rejection, however, are extremely insecure, as they depend chiefly upon nice distinctions and analogies of style between the two epistles, which are seldom drawn with such unerring accuracy as to induce us to attach very much weight to them.[2] The persons to whom these epistles were addressed were converted Jews scattered over the districts enumerated by the apostle in the commencement of the first of them. The epistles themselves are characterized by great vigour of conception, warmth of feeling, and force of eloquence. The style is glowing and rapid, approaching at times to vehemence; and the sentiments are of the most elevated description. The exhortation to holiness with which the second chapter of the first epistle concludes, is perhaps unequalled in the New Testament for the appropriateness of its sentiments, the beauty of its appeals, and the concentred energy and rapid flow of the style; nor would it be easy to find any passage, either in sacred or profane literature, that should surpass in vividness of description and power of expression the prophetic view of the end of the world with which, towards the conclusion of the second epistle, he enforces his exhortation to holy conversation and godliness. In both epistles we trace the characteristic ardour and the elevated piety of their author, and of both we may justly say, in the language of the excellent Leighton, that they are eminently adapted "to establish Christians in believing, to direct them in doing, and to comfort them in suffering, often setting before them the matchless example of the Lord Jesus, and the greatness of their engagement to follow him." (N. N. N. N.)

Peter *of Blois*, a learned man of the twelfth century, was born about the year 1120, at the city of Blois, in France, from which he derived his name. His parents being opulent, gave him a learned education. In his youth, when he studied in the university of Paris, he was excessively fond of poetry; and when he had advanced a little further in life, he became no less fond of rhetoric, to the study of which he applied with the greatest ardour. From Paris he removed to Bologna in Italy, to study the civil and the canon law, in the knowledge of which he very much excelled. From his writings it appears that he cultivated medicine, and several branches of the mathematics, with no little care and success. But the study of theology formed the chief delight and business of his life, and in it he not only spent the greatest part of his time, but made the greatest progress. Unfortunately, however, the theology he studied was of that scholastic kind, which consisted in vain attempts to explain and prove the many absurd opinions which then prevailed, by the subtilties of the Aristotelian logic. In attempting to explain the doctrine of the real presence, as held by the Latin church, he was the first who employed the famous term *transubstantiation*, which was soon afterwards adopted by the church, and has ever since been retained. Being appointed preceptor to William II. king of Sicily, in 1167, he obtained the custody of the privy seal; and, next to the Archbishop of Palermo, who was the prime minister, he had the greatest influence in all affairs. His power, however, was not of long duration; for the archbishop being banished in 1168, Peter soon afterwards left the court of Sicily, and returned into France. But in a short time he found another royal patron, having been invited into England by Henry II. who employed him as his private secretary, made him Archdeacon of Bath, and gave him some other benefices. Having spent a few years at court, however, he conceived a disgust at that way of life, of which in one of his letters he has drawn a very unpleasing picture, and retired into the family of Richard, archbishop of Canterbury, who had made him his chancellor about the year 1176. In this station he continued until the death of the archbishop in 1183, enjoying the highest degree of favour with that prelate, though he used much freedom in reproving him for his remissness in the government of the church. He continued in the same station in the family of Archbishop Baldwin, who succeeded Richard, acting both as his secretary and as his chancellor. In 1187, he was also sent by the latter prelate upon an embassy to Rome, to plead his cause before Urban III. in the famous controversy between him and the monks of Canterbury respecting the church of Hackington. After the departure of his friend and patron Baldwin for the Holy Land in the year 1190, our author was in his old age involved in various troubles, the causes of which are not distinctly known; and he died about the end of the twelfth century. He appears from his works, which may be justly reckoned amongst the most valuable monuments of the age in which he flourished, to have been a man of great integrity and sincere piety, as well as of a lively, inventive genius, and uncommon erudition. His printed works consist of a hundred and thirty-four letters, which he collected together at the desire of Henry II.; of sixty-five sermons, delivered on various occasions; and of seventeen tracts on different subjects.

[2] Horne's Introduction, vol. iv. p. 434, ff.; Sherlock's Dissertation on the Second Epistle of Peter.

Peter I, czar or tsar, and afterwards emperor, of Russia, was the founder of the Russian empire. That country was indeed well known, and of great antiquity; but it had no extent of power, of political influence, or of general commerce in Europe, until the time of Peter. He was born in 1672, and proclaimed czar when only ten years of age, in exclusion of John his eldest brother, who, being of a sickly constitution, was at the same time equally deficient in understanding. The Princess Sophia, his sister by the half-blood, raised an insurrection in favour of John; but, to put an end to the civil war, it was at last agreed that the two brothers should jointly share the imperial dignity. Peter had been very ill brought up, not only through the general defects of education in Russia, but likewise through the arts of the Princess Sophia, who surrounded him with every thing calculated to stifle his natural desire of knowledge and to deprave his mind. But notwithstanding this, his inclination for military exercises discovered itself in his tenderest years. He formed a company of fifty men, commanded by foreign officers, and clothed and exercised after the German manner. He himself entered into the lowest post, that of a drummer, and never rose otherwise than as a soldier of fortune. His design in this was to teach his nobility, that merit, and not birth, formed the only solid title to military employments. He reinforced his company with several others, until at last he had got together a considerable body of soldiers. As he had then no war on his hands, he exercised them in all sorts of mock engagements, and by this means secured to himself a body of well-disciplined troops. The sight of a Dutch vessel, which he had met with upon a lake belonging to one of his pleasure-houses, made such an impression on his mind, that he conceived the almost impracticable design of forming a navy. His first care was to get some Hollanders to build small vessels at Moscow; and he passed two successive summers on board of English or Dutch ships, which sailed out from Archangel, that he might instruct himself in every branch of nautical affairs. In the year 1696, the Czar John died, and Peter now became sole master of the empire. In 1698 he sent an embassy to Holland, and having gone *incognito* in the retinue, he visited England as well as Holland, to inform himself fully respecting the art of ship-building. At Amsterdam he worked in the yard as a private ship-carpenter, under the name of Peter Michaelof; but he has been often heard to say, that if he had never gone to England, he would still have remained ignorant of the art of ship-building. In 1700 he had got together a body of regular troops, amounting to thirty thousand infantry; and now the vast project he had formed displayed itself in all its parts. He opened his dominions, which till then had been closed, having first sent the principal nobility of his empire into foreign countries to improve themselves in knowledge and in learning. He invited to Russia all the foreigners he could meet with, who were capable of instructing his subjects in any respect, and offered them great encouragement to settle in his dominions. This raised many discontents; and the despotical authority which he exerted on all such occasions was scarcely sufficient to suppress them. In 1700, being strengthened by the alliance of Augustus king of Poland, he made war on Charles XII. king of Sweden. His ill success at first did not discourage him; for he used to say, "I know that my armies must be overcome for a great while; but even this will at last teach them to conquer." He afterwards gained considerable advantages, and founded St Petersburg in 1703. In 1709 he gained a complete victory over the Swedes at Pultowa. In 1712 he was surrounded by the Turks on the banks of the Pruth, and seemed inevitably lost, had not the Czarina Catherine bribed the grand vizier, and the czar's prudence completed his deliverance. In 1716 he made a tour through Germany and Holland, and visited the Royal Academy of Sciences at Paris. It would be endless to enumerate all the various establishments for which the Russians are indebted to him. He formed an army according to the tactics of the most experienced nations; he fitted out fleets in all the four seas which border upon Russia; he caused many strong fortresses to be raised according to the best plans, and made convenient harbours; he introduced arts and sciences into his dominions, and freed religion from many superstitious abuses; he made laws, built cities, cut canals, and executed many other works; he was generous in rewarding, and impartial in punishing; faithful, laborious, and humble, yet not free from a certain roughness of temper natural to his countrymen. He had indeed cured himself of excess in drinking; but he has been branded with several other vices, particularly cruelty. He published the unfortunate history of his son Prince Alexis, towards whom some blame his severity, whilst others think it no greater than was absolutely necessary. He perfectly knew the respect due to persons of merit; and not only heaped honours upon them during their life, but paid to their memory marks of esteem after their death. He died of the strangury in 1725, and is said to have left the world with the magnanimity of a hero and the piety of a Christian.

Peter *the Wild Boy*. This extraordinary creature at one time occasioned a great deal of speculation amongst the learned; but we do not know that any satisfactory causes have been assigned for the striking difference observed between him and other human beings.

The following account of him is extracted from the parish register of North Church, in the county of Hertford. "Peter, commonly known by the name of *Peter the Wild Boy*, lies buried in this church-yard, opposite to the porch. In the year 1725 he was found in the woods near Hamelen, a fortified town in the electorate of Hanover, when his majesty George I. with his attendants, was hunting in the forest of Hertswold. He was supposed to be then about twelve years of age, and had subsisted in those woods upon the bark of trees, leaves, berries, &c. for some considerable length of time. How long he had continued in that wild state is altogether uncertain; but that he had formerly been under the care of some person, was evident from the remains of a shirt collar about his neck at the time when he was found. As Hamelen was a town where criminals were confined to work upon the fortifications, it was then conjectured at Hanover that Peter might be the issue of one of those criminals, who had either wandered into the woods and could not find his way back again, or, being discovered to be an idiot, was inhumanly turned out by his parents, and left to perish, or shift for himself. In the following year, 1726, he was brought over to England, by the order of Queen Caroline, then Princess of Wales, and put under the care of Dr Arbuthnot, with proper masters to attend him. But notwithstanding there appeared to be no natural defect in his organs of speech, after all the pains that had been taken with him he could never be brought distinctly to articulate a single syllable, and proved totally incapable of receiving any instruction. He was afterwards intrusted to the care of Mrs Titchbourn, one of the queen's bedchamber women, with a handsome pension annexed to the charge. Mrs Titchbourn usually spending a few weeks every summer at the house of Mr James Fenn, a yeoman farmer at Axter's End, in this parish, Peter was left to the care of the said Mr Fenn, who was allowed thirty-five pounds a year for his support and maintenance. After the death of James Fenn he was transferred to the care of his brother Thomas Fenn, at another farm-house in this parish, called Broadway, where he lived with the several successive tenants of that farm, and with the same provision allowed by government, to the time of his death, 22d of February 1785, when he was supposed to be about seventy-two years of age."

Peter's Pence, the name applied to an annual tribute of one penny, paid at Rome by every family at the festival of St Peter. Ina the Saxon king, when he went in pilgrimage to Rome about the year 740, paid this contribution to the pope, partly as alms and partly in recompense of a house erected in Rome for English pilgrims; and the same continued to be paid generally until the time of Henry VIII., when it was enacted, that henceforth no person should pay any pensions, Peter's pence, or other impositions, for the use of the bishop or see of Rome.

PETERBOROUGH, one of the smallest English cities, situated in a corner of the county of Northampton, on the confines of Huntingdonshire, seventy-nine miles from London. The city is by the new municipal law governed by a mayor, with four aldermen and twelve councillors, and returns to parliament two members, who are chosen by householders, most of whose dwellings are the property of the Earl Fitzwilliam, who consequently has a preponderating influence in the elections. The buildings are moderately handsome. There is a well-supplied market, which is held on each Saturday; but though provisions are cheap, it is not populous, and, from the vicinity to the fens, is generally deemed unhealthy. The population amounted in 1801 to 3449, in 1811 to 3674, in 1821 to 4598, and in 1831 to 5553.

The most interesting object in the city is the ancient abbey, converted into a cathedral at the time when this place was created the see of a bishop by King Henry VIII. This ancient edifice was spared at the general destruction of the religious buildings, because, as is commonly believed, it had been the place of interment of Catherine of Aragon. It was at the time of the suppression a very rich establishment, and only a small portion of the revenues was applied to form the chapter, which, besides the bishop, consisted of a dean, six prebendaries, a divinity reader, eight minor canons, and the same number of lay clerks and singing men. The present edifice was begun in the year 1117, but not finished till the year 1143. It had some additions made to it in the year 1177. Between the years 1200 and 1222 it was improved by the addition of glass windows. After the Reformation, it suffered much from the democratic party; but, in its present state, it exhibits some fine specimens of the architecture of remote ages. This church has one advantage over most of the other cathedrals, that it is less encumbered with surrounding buildings. The precincts are entered from the town under a Gothic archway, when the most imposing part of the building is at once displayed to the view; we mean the west front, to which there is nothing in Gothic architecture in England that will bear a comparison, except the west front of Wells Cathedral, and that of Rheims in France, both of which, though equal in extent, are far inferior to it in form, proportions, and general effect. There is a solemnity in the effect which it produces, observable in no other cathedral, and which is not unmixed with awe. There are other parts of this edifice much admired, such as the beautiful building which surrounds the choir, the central tower or lanthorn, the ceiling of the nave, the organ-screen, and the cloisters. The whole of this edifice has been beautified, improved, and ornamented, by the liberality of Dr Monk, now bishop of Gloucester.

The dimensions of the cathedral are as follow: The breadth of the western façade is a hundred and fifty-six feet; the length of the nave from the western wall to the entrance of the choir is two hundred and six feet, the breadth of it being thirty-five feet; the length of the transept is a hundred and eighty-four feet; and the length of the choir, from the entrance to the eastern extremity, is a hundred and twenty-eight feet. The total external length of the cathedral is four hundred and seventy-nine feet; the general height, from the pavement to the ceiling, is eighty-one feet, and to the top of the lanthorn a hundred and thirty-five feet.

The income of the bishopric is not large. In the king's books it is charged at L.4141. 7s. 8d. per annum; but the gross value, according to the parliamentary return made by the bishop, is no more than L.3518. By the recent law it is to be augmented by the application of a portion of the revenue of the see of Ely; and, by the same law, the archdeaconry of Leicester is placed under the episcopal jurisdiction of the bishop of Peterborough.

PETERHEAD, a parish of Scotland, situated on the east coast, in latitude 57. 34. N. and longitude 1. 35. W. in the district of Buchan, and county of Aberdeen. It extends along the coast in a straight line about four miles, bending along the sea-shore about five miles; and from east to west it extends from three to four miles. The surface is nearly level along the coast. The Stirlinghill and Blackhill, containing extensive quarries of granite, are on the southern and western boundaries. The surface of the parish extends to upwards of 9000 imperial acres, of which about 8300 are under cultivation, 72 are planted, 500 are capable of cultivation, and the remainder is chiefly rocky. Extensive improvements in the cultivation of the soil have been made within the last thirty years. The rental of the landward part of the parish is about L.10,000. The population amounts to 7867.

Peterhead, a burgh in the parish of the same name, in the county of Aberdeen, is situated upon the most easterly point of the mainland of Scotland. Previously to 1593 it was a small fishing village. In that year it was erected into a burgh of barony by George, earl marischal. It was forfeited in 1715, and purchased by the York Building Company, from whom the present proprietors, the governors of the Maiden Hospital founded by the company of merchants of the city of Edinburgh, and Mary Erskine, acquired it by purchase in 1728. The superiors had the nomination of the magistrates until the passing of the burgh reform act in 1832, by which the municipal government has been vested in twelve councillors, who from their own number choose a provost, three bailies, and a treasurer. The town contains about 1000 inhabited houses, besides warehouses, and the rental is about L.7500. The boundaries of the town have been considerably enlarged under the burgh reform act, and now embrace the village of Buchanhaven, and part of the lands of Invernettie.

The harbours of Peterhead are extensive; and, from their peculiar position at the termination of the most easterly promontory of land in Scotland, having an entrance both from the south and north, and being about equally distant from the Friths of Forth and Moray, much resorted to by vessels frequenting the east coast of Scotland, and affording, as they do, shelter and protection, not only to the trade of the port, but also to shipping in general frequenting the east coast of Scotland, they deserve attention in a national point of view. About L.47,000 have been expended in building these harbours. They are managed by commissioners incorporated by act of parliament, and yield an annual revenue of about L.2800. The south harbour embraces an area of 6·16 imperial acres, having from twelve to fourteen feet water at medium springs, and from eight to ten feet at neap-tides. The north harbour, which has an area of 10·86 imperial acres, has at spring-tides eighteen feet water, and never under fourteen feet on any tide. The quays extend to about 3350 feet in length. Connected with the harbours there is an excellent graving-dock. The shipping belonging to the port amount to about 13,000 tons. The number of vessels which annually take shelter in the harbours may be stated on an average at 240. The leading articles of export are grain, meal, eggs, butter, cattle, fish, and the produce of the fisheries. The imports are groceries, clothiery, flour, salt, iron, timber, coal, lime, bone manure, &c. An extensive trade to Greenland and Davis' Straits has been carried on from Peterhead with various success since the year 1788. During that time 3020 whales have been caught, which have yielded 30,296 tons of oil. The herring fishery has of late been carried on with great success. In 1837, 262 boats were employed in this fishery, and upwards of 40,000 barrels of herrings were caught. It is supposed that Peterhead, being situated farther east than any other land in Scotland, must at all times be one of the best stations for carrying on the herring fishery, as, if the herrings pass along the coast, they must pass near to this headland, and as the tides are strong, only the best fish can make head against them; and, in fact, it has been found that those caught at Peterhead are of superior quality. The lighthouse, which stands on the Buchan-ness, at the extremity of the south bay, is of the utmost importance, both as regards the interests of the general trade of the port, and the prosecution of the herring-fishery. A considerable trade is occasionally carried on in granite from the quarries in the neighbourhood. The stone, which is generally of the red granite, and of excellent quality, may be raised in large blocks. The pillars in the British Museum, the docks at Sheerness, the pillar erected in London to the memory of the late Duke of York, and many other public works, have been built of granite from Peterhead.

In former times Peterhead was much resorted to as a watering-place; and as it certainly possesses many advantages to the invalid who requires sea-bathing and the tonic effects of the mineral waters, it held a high rank amongst the places of summer retreat for upwards of two centuries. Perhaps no place in the island is more suitable for those whose cases require the bracing effects of sea-bathing or sea-air; the former, from the rapidity of the tides and the absence of rivers, being to be enjoyed in the greatest possible perfection; and the latter, from the almost insular situation of the place, and the total absence of all muddy or marshy exhalations, or other sources of contamination, affording all the advantages without the inconvenience of a sea-voyage. In many cases much benefit may also be derived from the use of the chalybeate waters with which the neighbourhood abounds. But perhaps the renovated health and spirits which are in most cases the result of a season at Peterhead are mainly to be attributed to the air and bathing, together with the regular hours and habits which such a residence naturally inculcates.

The town is plentifully supplied with excellent spring-water, which within the last few years has been brought at a great expense for the use of the inhabitants and the shipping; and it is now lighted with gas. There are no manufactures of woollen or cotton goods in Peterhead, although, from its situation, there is every reason to believe that such manufactures might be carried on with advantage.

The places of worship are, the original parish church, the East parish church or chapel of ease, the Episcopal chapel, and the United Session, Congregational, and Methodist meeting-houses. In the town there is a news-room, and also a reading society, who have a large and valuable library; and there have lately been established an association for the promotion of science, literature, &c. and a mechanics' institution. There is a weekly market, which is held on Friday; and there are two annual fairs, viz. on the third Tuesday in May and the second Tuesday in November, both old style.

Petersburg.

Of late years the town has very much increased, both in inhabitants and in trade and shipping. The inhabitants are intelligent and industrious, and therefore there is reason to anticipate the future extension and prosperity of the burgh. The population of the town in 1838 amounted to 6200. The number of qualified electors was 211.

PETERSBURG, St, a city, in the most northern situation of any large place in the globe, its observatory being in latitude 59. 56. 13. N., and in longitude 30. 17. 33. E. It was almost from its origin the second, and has of late become the first city of the Russian empire; its population having in the course of the last few years exceeded that of Moscow by more than 100,000 inhabitants, being at the close of 1836, including the military, 499,000.

The origin of most of the other European capitals dates from a period so remote that the date of their foundation is a matter of doubt and a subject of controversy; but St Petersburg is a comparatively modern city, having been raised to consideration almost instantaneously, and in little more than a century having attained its present extent. It is situated in what formed a part of the Swedish province of Ingria, or Ingemannland, till, in consequence of the victory of Embach in January 1702, gained by the Russians over the Swedes, and the peace which followed it, the territory was obtained by the former, then under the sway of the Czar, afterwards the Emperor Peter, better known by the distinguishing title of Peter the Great.

Peter, soon after his accession to power, had felt the importance of communication with foreign lands as the means of introducing civilization amongst the rude and barbarous people over whom he ruled, and consequently began to direct his attention to maritime affairs. As early as 1693, Archangel was his chief northern port; but he soon afterwards looked towards the southern part of his dominions, and constructed an arsenal on the river Don, at Woronesh, where he built a sufficient number of armed vessels to secure to himself a superiority on that river, and the safe access to the Sea of Asof, which was accomplished by the year 1696. He had become so attached to affairs of a maritime nature, that the year after, in order to qualify himself to conduct them properly, he resolved to visit the western shores of Europe, and, as a real workman, to become familiar with the whole process of building, equipping, arming, and fighting a fleet of ships of war.

He spent much time in Holland working in the ship-yards, and some time in the dock-yard at Deptford, whence he frequently, in his working dress, visited King William at Windsor, and once went to Oxford, where a doctor's degree was conferred upon him. During his residence in England and Holland he engaged to repair with him to Russia more than five hundred persons, consisting of military and naval officers, engineers, surgeons, and artificers of various kinds. He was recalled home by an insurrection, which was soon suppressed, and the participators in which were dreadfully punished. A war then broke out with Sweden, in which he was at first unsuccessful, until his army had learned of their enemies to conquer them. The result of that war was the possession of that spot of Finland where the river Neva runs from the Lake of Ladoga into the Baltic Sea.

When Peter had thus gained the district, his first intention was merely to erect a strong fortress, the foundation of which was laid on the 27th of May 1703, and more than 20,000 men were collected at the spot to execute the work. Whilst this work was proceeding, a thought struck Peter that this would be the most appropriate spot for the erection of a northern capital, from which a maritime intercourse might be maintained with the other European powers. With the rapidity of action that usually followed his resolves, this measure was commenced. Artificers were collected from all parts; and abundance of working men were furnished by the events of war, from Sweden, Livonia, and Finland. The ground for houses was given to those who built them; and many of the nobility were induced, if not compelled, to erect mansions, by which employment was given to those who possessed nothing but their labour. Within two years from the commencement of the city, those parts of the city now called the Admiralty quarter and the Peter's Island quarter were covered with splendid dwellings, where, before, there had stood only two fishermen's huts. The trade was slow in reaching the new city. In the year 1714, it had been visited by sixteen foreign ships. In 1730 the number was 180; and since that time the increase has been gradual up to the present day, when they are more than 1500 annually. After the year 1714 the city was declared to be the seat of government, the emperor also making it his residence, upon which splendid buildings were erected for the various public offices. Since that period there has been an increase both of inhabitants and edifices; but the most rapid advance has been from the year 1816 to the year 1836.

Had Peter been in possession of Livonia at that time, it is probable he would have selected Riga for his northern capital, rather than the spot on which St Petersburg now stands, as it enjoys a climate in some degree more temperate, and has an easier access to its harbour, as well as a more secure and capacious bay without it. St Petersburg, in fact, has no harbour; but its sea-port is the city of Cronstadt, which is the chief station of the imperial navy and of the merchant-ships. It is built on the Kotlen Island, which is about six miles in length, and is composed almost entirely of sand, except a ridge of granite, which runs through the centre of it. Cronstadt city, on the south-eastern part of the island, has about 50,000 inhabitants. It is fortified both towards the land and towards the sea, and has two havens for ships of war and one for trading vessels. The principal men-of-war's port has sufficient space for thirty sail of the line, but not sufficient depth of water for such a number, and some are obliged to remain in the middle port. The merchant's haven is closed by a boom, and defended by a battery on each jetty-head. A canal, twenty-five feet in depth and fifty-two feet in width, begun by Peter the Great, and completed by the Empress Elizabeth in 1752, leads to the dry docks, which are 150 fathoms in length. When the docks are filled, as there is no flux and reflux of the tide, they can only be emptied by pumps worked by steam-engines; an operation which it requires eight or nine days to perform. It is about twenty miles from Cronstadt to St Petersburg by water. The channel is contracted by shoals in the narrowest part to about half a mile. In some parts the water is only from six to seven feet in depth, except when strong westerly winds raise it a foot more. The goods from and to the merchant-ships, as well as the warlike stores for the arsenal, are conveyed by lighters; and of late steam-tugs have been introduced, to facilitate the passages of these lighters. The whole banks are powerfully protected by batteries and by Cronstadt Castle. The city of St Petersburg was originally founded on portions of land either pure sand-banks or marshes, through which the river Neva, from the Lake of Ladoga, forces its way with a most tortuous course, forming islands in the way to its several mouths. These islands are now component parts of the city, being for the most part covered with buildings, connected by bridges over the branches of the stream that divide the city and the numerous canals, which in various directions intersect almost the whole surface. The most extensive part of the city, that in which the admiralty stands, is nearly a peninsula, enclosed in a bend of the stream called the Great Neva. The abundance of internal water communication is to St Petersburg, as to the other aquatic cities, Amsterdam, Rotterdam, Hamburg, and Venice, a great benefit to commercial operations, as the lighters can be loaded or discharged directly from or into the storehouses of the merchants.

The bridges across the streams and the canals, with the exception of one of iron over the Moika, are constructed of barges built on purpose, moored with cables and anchors at each end, and covered over with planks, to enable carriages to pass. At the commencement of winter, when the Neva begins to freeze, lumps of ice are first seen floating; and when these appear the bridges are immediately taken to pieces. During one or two days the pieces of ice drift with the stream, and the river is crossed in boats; but the increase of the ice is so rapid, that it is not unusual to see, within the space of two hours, the river covered with boats, and people walking on the ice. In the spring, the breaking up of the ice generally occurs suddenly, and it floats in large masses down the stream. When the river is clear, the circumstance is made known by the firing of cannon and by other public demonstrations, and is usually accompanied with joyous festivals. A traveller who visited this city in 1806 relates, that on the 8th of November the river was covered with floating ice. On the same day the bridges of boats, their anchors being drawn up, were swung round to the two opposite shores, and remained there till the thaw took place, on the 11th of May. In two days the river was completely thawed, although, just before, men, women, horses, and carriages, had been passing over it upon ice five feet in thickness, and a week before they had held a fair, and raced in sledges. The sudden breaking up of the frost is one of those physical evils from which St Petersburg is peculiarly liable to suffer, and has suffered at various periods, but most severely in the year 1824. When the water from the Lake of Ladoga is impeded by the masses of ice in the Neva, an inundation of a most extensive nature is occasioned, and visits the inhabitants of St Petersburg, especially those of the lower classes, with most terrible sufferings.

The means of maintaining intercourse by sea with the rest of the world having been noticed, it becomes natural to turn our attention to the foreign trade actually carried on at St Petersburg. Its position, in spite of the severity of the climate, and the long duration of the winter, is favourable for the transmission thither of the native products from the greater portion of the surface of that vast empire. Rivers of great length empty themselves into the lake of Ladoga, an inland sea more than one hundred miles in length and sixty in breadth. These rivers are at great distances from the metropolis, connected, by means of artificial canals, with other streams running in different directions. Thus, the products of the southern provinces may be exported either from the Baltic or the Black Sea ports, as the markets may be more beneficial, or the means of internal conveyance may be more or less costly. On the rivers and canals here alluded to, the heavy goods are conveyed by water while these continue open; whilst, on the other hand, during the long frosts, when the whole surface is buried in deep snow, they become, when once settled or beaten down, excellent roads, on which the heaviest commodities can be conveyed by sledges at a less cost than by water. In fact, the frozen roads, rivers, and canals, have an effect on Russian interchange of products similar to what may be experienced in this country when the numerous railroads now projected shall be carried into execution.

It is from these facilities of internal intercourse that a city so large as St Petersburg, in a district of little fertility, and in a climate which closes its port during nearly half the year, is not only abundantly and cheaply supplied with all the necessaries of life for its own consumption, but has become the emporium of the foreign commerce of the empire, as regards both its exports and its imports.

It appears by the returns from the Russian custom-house, that the commerce of St Petersburg, with its dependent port of Cronstadt, in the two years 1830 and 1831, employed rather more than double the number of vessels required for all the other commerce of the empire; but the amount of duty collected there was about four times as great as that at all the other ports.

As our limits do not allow of inserting the tables necessary to show the rate of increase of the foreign trade of St Petersburg, we must confine ourselves to the exhibition of it at the latest period for which accurate documents are accessible.

Statement of the Trade of St Petersburg for 1834.

Or, in sterling money, L.4,777,992.

Although by these accounts the excess of imports much exceeds that of exports, yet, as the reverse is the case at the neighbouring port of Riga, the balance is nearly equalized in the whole trade of the Baltic.

The following is a summary of a report made by the Russian minister of finance, on the exports of St Petersburg during the year 1837. Copper, 6,078,060 lbs.; iron, 26,448,960 lbs.; raw hemp, 79,579,440 lbs.; spun hemp, 2,205,120 lbs.; cordage, 13,624,080 lbs.; oil of hempseed, 10,268,600 lbs.; bacon, 153,662,200 lbs.; tallow candles, 500,760 lbs.; soap, 60,799 lbs.; caviare, 76,080 lbs.; wool for mattresses, 1,211,360 lbs.; hogs' bristles, 1,945,680 lbs.; horse-hair, 572,720 lbs.; feathers, 896,200 lbs.; down, 51,480 lbs.; eider-down, 128,040 lbs.; aniseed, 75,160 lbs.; antimony, 341,040 lbs.; dressed skins, 14,374 pieces; undressed skins, 56,492 pieces; mattresses, 183,368; sail-cloth, 49,634 pieces; sack-cloth, 183,314 pieces; military cloth, 58,275 pieces; Flemish cloth, 68,172 pieces; cloth for towels, 7,540,394 ells; woollen cloth, called kalamaika, 1,582,024 ells; cotton cloth, called hracatscha, 13,491,260 ells; linseed, 3,632,212 bushels; rye and oats, 962,598 bushels; timber and planks, 2,786,104 pieces. This merchandize has been exported in 1248 vessels, the greater number of which belong to Russia, England, and the United States of America.

An Account of the Number and Tonnage of Vessels which entered the Port of Cronstadt in three years, ending with 1831, *distinguishing the Countrics to which they belonged.*

It thus appears, that of the trade of St Petersburg in the three years here exhibited, whilst the whole tonnage amounted to 798,632 tons, that of Great Britain alone was 507,342 tons, or somewhat more than five eighths of the whole.

In connection with trade, it may be proper to notice the singular and semi-barbarous regulations under which the mercantile community are placed. They are divided into three classes, which are called guilds. The merchants of the first guild have very extensive privileges. They may import or export any quantity or quality of goods permitted in the tariff, and sell or buy bills of exchange; in fact, they have the same privileges as the most favoured mercantile community in any part of Europe; and, in common with the nobility, they may have four horses to their carriage, and may possess country-seats and houses in town. Those of the second guild may transact all kinds of wholesale inland business, but they have no right to export or import on their own account, neither are they allowed to sell any bills of exchange, although they are not debarred the privilege of purchasing them. They can only use two horses in their carriages; and although they may possess houses in town, they must not be owners of country-seats. The third guild is composed of all descriptions of shopkeepers and retail-dealers, who are obliged to purchase their supply of stock from merchants of the two other guilds. All craftsmen belong to this class. There are instances in which craftsmen carrying on business on an extensive scale have been allowed to set up their carriage, and purchase property wherein to transact their business; but the mercantile members of the third guild are entirely excluded from this privilege, it being considered that they never lay in so large a stock as to require so extensive premises. They may only keep a horse and cart or sledge. Foreigners who wish to transact business may reside here as strangers, but they are obliged to take a license as merchants of the first guild, in which case they have the same privileges as the most favoured of that class, excepting only the right of holding real estates. There are some of the shopkeepers, and amongst them men of very large fortunes, who are not freemen, but pay a yearly tax to their masters for the liberty of residing out of his estates. The possession of their fortunes is very precarious, it being at the option of their lords to cancel the permission of absence.

---

[1] The pood is a Russian weight of thirty-six pounds avoirdupois.

[2] Or L.6,634,748, the rouble being valued at the twenty-fifth part of a pound sterling.

As St Petersburg is the great conduit through which the supply of the wants of almost the whole of Russia, with its population of more than fifty millions of inhabitants, is transmitted, we must take notice of the internal means of collection and distribution which the city enjoys. It appears that in a series of years there arrive annually about 12,000 vessels from the interior, loaded with goods. These are denominated barges, galliots, or boats; besides which there are about 5000 floats or rafts of wood for fuel, for building ships, or for constructing houses. The value of the goods thus brought has been estimated at about 125,000,000 of roubles, or L.5,000,000 sterling. The number of this craft that is despatched with cargoes does not much exceed one tenth of those that arrive; but as they are of the best description, the value of the goods they convey back is calculated to amount to near L.1,000,000 sterling.

It may be seen by the former accounts of exports, that the whole annual amount nearly equals that which is here shown to arrive from the interior, and that these exports are chiefly composed of raw materials. It is obvious, then, that the manufactures which the city furnishes to foreign commerce must be of very inconsiderable amount. In fact, it will be seen, by the short notices given in the sequel, that they are chiefly calculated for home consumption, or to be presented to individuals, as marks of the emperor's esteem. The manufactories of china, and especially of glass, are the most distinguished. Of these there are six or eight large establishments in the city and within a few miles of it.

In the imperial glass manufactory mirrors are cast of larger dimensions than any which have issued from the fabrics of the same kind at St Ildefonso, Paris, or London. The largest was presented to Prince Potemkin, and measured sixteen feet two inches in height, and eight feet four inches in breadth. Another of the same dimensions was made for the Duke of Wellington; and some of less size have been presented to other distinguished personages at home and abroad. The cut glass made here is remarkable for elegant designs, and the peculiar purposes for which these are contrived. The crystal bed designed as a present to the shah of Persia may be mentioned as an instance.

The porcelain manufactory employs more than a thousand persons. The paintings on the china are chiefly executed by foundlings trained to the employment. The gilding is said to be superior to that executed at Sèvre or Dresden. The fabric is chiefly devoted to making objects of taste and luxury, and yields but little advantage in a commercial view.

The iron-founderies are upon a large scale; and there are, besides, under the patronage of the government, some establishments for making steam-engines, such as the various descriptions of machinery applicable to the spinning and weaving of cotton, linen, and silk goods, and the manufactory for making playing-cards, which gives employment to more than a thousand foundlings of both sexes. One of the most considerable establishments is about twenty miles from the city, and serves to supply every kind of store for the fleet, whether in the Baltic, the White Sea, or the Black Sea. Its management is praised by Captain Jones of the royal navy, who, speaking of it, says, "They must watch us closely, and have the best intelligence; for almost every nautical invention that is considered as an improvement in our service is made and to be seen at Kolpina."

The facilities afforded to commerce are in St Petersburg quite equal, as regards banks, to that of the other trading cities of Europe. The Commercial Bank has a capital of 30,000,000 roubles, or L.1,400,000; but it also takes in money on interest, and lends it at a trifle higher, on good security. The Loan Bank is of nearly the same power, and performs similar operations. Besides, there is the Lombard or Mont de Piété, an establishment for lending money on jewels, plate, or goods of any kind. It has a capital of 50,000,000 of roubles, or L.2,000,000 sterling, the interest arising from which is appropriated to the support of the great foundling hospitals of Moscow and St Petersburg, and to some other charitable institutions.

The following classification of the inhabitants of St Petersburg in September 1832, according to a consular return, seems properly to precede any view which can be taken of the edifices of that city. By this authority the progressive growth of the population is shown as ascertained at four different periods. In 1810 it amounted to 250,000, in 1820 to 350,000, in 1830 to 448,649, and in 1832, as stated below, to 479,993. The numbers given for 1810 and 1820 are deduced from calculation, but they cannot be far from the truth; those for the last two years were obtained by actual numerations. The increase is not supposed to have been at the same rapid rate between 1832 and 1837.

A Statement of the Population of St Petersburg, distinguishing the Classes and Sexes, in September 1832.

Classes.	Males.	Females.	Total.
Clergy	1,034	740	1,774
Nobles	24,342	18,426	42,768
Merchants	7,121	4,319	11,440
Burghers	25,914	14,789	40,703
Foreigners	9,160	5,502	14,662
Military	45,324	9,883	55,207
Artisans	7,020	4,065	11,085
Servants	68,480	34,457	102,937
Peasants	116,974	24,752	141,726
Various	33,877	23,814	57,691
	339,246	140,747	479,993

The great disproportion between males and females is a peculiarity in this city. Whilst in London the females exceed the males nearly in the proportion of seven to six, and in most of the other capitals the numbers of the sexes approach to equality, the above table shows that in St Petersburg the males exceed the females almost in the proportion of three to one. On looking to the increase before stated, it appears the more extraordinary that it should have taken place with so few females; and hence it may be concluded, that the drain on the general population of the empire to supply the mortality of this northern capital must be much greater than in the other European countries.

The view of St Petersburg first strikes a beholder with more surprise than is experienced on entering any other of the great cities. This is more impressive from the contrast of the wretched-looking country which is passed through on approaching it by land. The streets are wide, straight, and well paved for both foot-passengers and carriages; and some of them long, especially two, which run diagonally from the Admiralty to the extent of more than a mile. These streets on both sides are filled with public buildings of a bold style of architecture, many of them belonging to the several branches of the government, or to public institutions; numbers are also occupied by the nobles and other distinguished individuals, and thus on the whole give to St Petersburg some title to the appellation of "the northern city of palaces." It is, moreover, to a stranger, who is not aware of the peculiar structure of society here, not a little surprising to remark the total absence of those dark and wretched courts and lanes, the abodes of the lowest classes, which in other cities obtrude themselves on the notice of the traveller in the midst of grandeur and stateliness of exterior. The greater streets run parallel or nearly so to each other, and are intersected at right angles by others called lines, which have no names given to them, but a number to each. Every house is numbered; and, besides, the name of the occupier must be exhibited on the outside, and is most commonly painted on a board affixed to the wall. As the soil on which St Petersburg is founded may be said to be marshy, most of the houses are built on piles, as at Amsterdam, Rotterdam, and Venice, the ground not being sufficiently firm to afford a good foundation of stone without them; but no inconvenience is found to arise from this circumstance, either with regard to health or to comfort.

One of the most remarkable features of this great metropolis is undoubtedly the Neva, a river which, whether we consider its origin, its great rapidity, its depth, and the beautiful transparent-blue colour of its water, impresses the beholder with delight very different from what is experienced in looking at the Thames, the Seine, the Po, the Tiber, the Vistula, or the Elbe. It may best be compared with the Rhone as it rushes out of the Lake of Geneva. As before remarked, this stream is crossed by various temporary bridges, resting on pontoons, as are also some smaller streams that fall into it, and contribute to form the several islands upon which the city is built. The quays on the Neva form objects worthy of much admiration. Most of them are built of granite, and one of them, more than two miles in length, is raised upon piles ten feet above the common level of the water. Between the water and the buildings there is a carriage-way from thirty to forty feet in breadth; and at certain distances are placed handsome flights of stairs, for loading and for embarking, and for procuring water, with seats for the accommodation of passengers. The canals are in the summer season favourable for conveyance from one part of the city to another; and abundance of boats are provided, conveniently fitted up for passengers. In the winter, these canals, as well as the streams, being frozen, make very good roads for travelling on by means of sledges, which move with almost incredible celerity. Carriages of various kinds, both for winter and summer, are abundant in many parts of the city, at cheap rates; but they are represented as neither elegant nor easy to the traveller.

In a city like St Petersburg, the seat of the central government of a country containing more than 50,000,000 of people, and where the public offices are of a number and extent commensurate with such a population, it would occupy too large a space to describe each public edifice; but the peculiar magnificence which distinguishes many of them will not allow of their being passed over.

Before mentioning the palaces belonging to the emperor and the imperial family, the magnificent gate at the entrance to the city deserves to be noticed. It is built of granite, and consists of one bold arch of a noble but simple style of architecture, supporting an entablature, on which are raised vases of white marble. It was built to commemorate the victories obtained over the French on the return of the army which had achieved the capture of Paris. Through this arch is seen the winter palace of the imperial family. It is a grand and imposing structure, in a square form, three sides of which are unencumbered with any other building. The north front, looking on the Neva, is 720 feet in extent, one fourth of which line, at each extremity, projects twenty-four feet from the centre. It is composed of a basement story of the Ionic order, surmounted by a principal and a second story of the Corinthian order. The roof is surmounted by a light balustrade, adorned with vases and with statues. The Corinthian columns and pilasters, placed between the windows of the principal and the second story, twenty-six of which are single and six double, are about thirty-five feet in height. This is considered as the finest elevation of the building. Some critics have maintained that the style of the building is heavy; whilst others justify it, on the ground that so great a mass of front requires less of that airiness which is appropriate to buildings of smaller dimensions. As a whole, however, it is allowed to be more striking in its appearance than any of the royal palaces in Europe, excepting, perhaps, that at Madrid, which, though smaller, has a more imposing front. In dimensions it exceeds them all, and yields to none of them in internal decorations. The quay between the palace and the Neva is much wider than any other in the city. The south side of this palace looks into a square, and the view is terminated by the Admiralty, a structure to be noticed hereafter. The ordinary entrance is by a large door in the centre of the west front, in which are the apartments occupied by the reigning empress and the imperial children. The principal entrance is on the south side, in the centre, and is covered with a lofty portico, under which carriages drive and are sheltered from the weather. This leads to the grand or parade staircase, a flight of marble steps remarkable for the grandeur and magnificence of its architecture, and for the gilding, the paintings, and the various other decorations.

It would be an endless task to attempt a description of the different apartments of this palace, which occupies an area of 400,000 square feet. There are from ninety to a hundred apartments in the first story. The most striking of them is the great banqueting-hall, a noble apartment, 190 feet in length and 110 in height. It is incrusted with the finest marbles, with a row of columns at each end, and the sides are decorated with marble columns, enriched by gilding and by mirrors of the largest size. The other grand apartments in this edifice are St George's hall, 140 by 60 feet, the richest and most expensively furnished of any room on the Continent. It is used for the reception of ambassadors, and for holding the chapter of the military order of St George. The Salle Blanch, or Whitehall, is a similar room, equal in dimensions, but more chastely and less expensively decorated; and so is the military gallery, which is 180 feet in length. It is lighted from the top; and, besides circles representing wreaths of laurels descending from the ceiling, has numerous rich and splendid candelabras, for the purpose of illuminating the gallery. The walls are wholly covered with half-length portraits of military and naval men who have distinguished themselves. The greater part of these portraits are said to be admirable likenesses, and most of them were executed by an eminent English artist, particularly that of the Emperor Alexander, twice as large as life, on his white horse, which is placed in a recess, the light being so managed as to throw on the painting additional beauty and animation. Adjoining to this, called the Winter Palace, are two other edifices, called the Great and Little Hermitage. These parts are a continuation of the Winter Palace on its eastern side, connected by covered galleries upon arches which cross two streets. Beyond these there is a third building, containing the theatre, joined to them by means of another great arch over a canal which connects the river Moika with the Neva. These three buildings present a frontage towards the Neva of 776 feet, making, with the continuation of the Winter Palace, a line of imperial palaces of more than a third of an English mile in length.

The interior of these palaces is most gorgeously decorated, and contains apartments enriched with collections of the fine arts. The rooms of painting are filled with the works of the most celebrated artists, which are arranged conformably to the various schools, viz. the Flemish; the Italian of the several stages, in six apartments; the Rembrandt, with the most valued of that master; and the French school. In the same apartment may be seen a collection of the best pieces of the Dutch masters, Teniers, Gerard Dow, Vandevelt, Vandemeer, and others. Other apartments contain pictures of the Spanish artists, amongst which are some of the most valued pieces of Murillo, and also a great number of Raffaelle, and the collection from Houghton in Norfolk. Cabinets of mineralogical specimens are formed in these parts of the buildings, besides vases of the best porcelain, and a vast variety of engravings. It would be tiresome to enumerate the most striking objects contained in this repository of antiques, cameos, statues, bronzes, and other articles of *vertù* which adorn these hermitages, designed by the Empress Catherine as a retreat from the parade of a court and the bustle of public affairs. In the library collected by her in this spot there are 110,000 volumes of all languages, amongst which only 10,000 are in Russian. The theatre of the Hermitage is not large, and has no boxes; the seats for the audience rise like an amphitheatre; and in front there are several richly decorated arm-chairs for the members of the imperial family. The interior of this theatre is superbly decorated; whilst its exterior, as seen from the quay, is considered as one of the happiest efforts of architecture.

Few objects present more of novelty, and excite more of surprise, than the gardens attached to these buildings. The winter garden is a large quadrangular conservatory, planted with laurels and orange trees, in which linnets and canary birds are allowed to fly about at perfect liberty. The summer garden is in the form of a parallelogram, 392 feet in length, and entirely composed of artificial soil, raised forty-two feet above the surrounding ground. Here, suspended as it were in the air, the visitor, to his amazement, treads upon gravel walks, sees the green turf around him, and finds shrubs, and even trees, growing in luxuriance. The novelty of the whole scene, and the recollection where it is situated, not on the ground, but on or near the top of a palace, produces an overpowering effect, and gives the feeling excited by other parts of the Hermitage, and confirmed by this concluding scene, that the sight of it alone is worth a journey to St Petersburg.

The other palaces cannot be wholly passed over, though it may only be necessary here to notice them very shortly. The Marble Palace, once belonging to Orlof, but now to the crown, is remarkable for its richly gilded ornaments, and the number of its marble columns. The Taurida Palace, in which Potemkin gave his splendid entertainment to the empress, and which has devolved to the crown, is remarkable for the furniture of its splendid apartments, but especially for its theatre, in which the front parapet of the boxes is made of solid cut crystal, with a contrivance to admit lights behind them, so as at night to throw a dazzling splendour around the audience. The Palace of Nevskoi Prospekt, on the quay called Fontanka, is remarkable for its handsome exterior, as well as for the imperial cabinets appertaining to it, in which the private treasure of the emperor, his state robes, and his armoury, are kept.

The Imperial Mews is remarkable for the splendour of its architecture. The principal front and superb elevation face a spacious square, on the opposite side of which there is a range of buildings for the accommodation of those belonging to the establishment. The centre of the principal front is occupied by a church for the Mews, in a Grecian style of architecture, and on a scale commensurate with the imposing attitude of the entire edifice. This edifice is the work of Trombara, an Italian artist, and the exterior is in most excellent preservation, great care being taken to keep the whole of these stuccoed buildings in an unsoiled and delicate white tint.

The triumph of modern architecture in St Petersburg is eminently visible in the recently-erected palace, called, from the prince who occupies it, the Palace Michaeli. It has been constructed by an Italian architect named Rossi. It was begun in the year 1819, and completed in 1825, at an expense of seventeen millions of roubles, or L.680,000, including the furniture, which is almost wholly the work of native Russians. This magnificent structure presents a front 364 feet in length, and consists of a main body and two projecting wings. In its interior it combines every thing that decoration, rich and beautiful workmanship, and costly material, conducted by consummate skill and pure taste, can accomplish. It is especially remarkable for the suitableness of the plan, which was designed as well for comfort as for magnificent display; and it would be difficult to find in St Petersburg, or in any other capital, an instance of a residence, every subdivision of which is equally well calculated for its individual purpose, and yet neither interferes with nor injures the usefulness and effect of the rest, or of any part of the structure.

After the splendid palaces of the imperial family, the buildings in which the affairs of the several branches of the government of the vast country are conducted require to be noticed. The senate-house, though not in its exterior very remarkable, is so from its vast extent, the prodigious quantity of business carried on, and the corresponding number of official persons employed in it. It is a quadrangle, covering an area of about 14,000 square feet, or somewhat more than one third of an acre. In one of the halls, which serves as a conference-room, within a kind of temple made of solid silver, the original manuscripts of the code of laws given by the Empress Catherine are preserved, all of which are said to be in her own handwriting. The front of this building faces the statue of Peter the Great, and, from its situation, forms the north-west angle of the Square of Isaac. Close to the senate-house, and forming the opposite side of Isaac Square, is the western wing of the Admiralty, an edifice which, in its present state, may with truth be represented as without a parallel in any part of Europe. Its principal front upon the land side measures more than one third of an English mile in length, and its depth extends, to the edge of the water, six hundred and seventy-two feet, or one eighth of a mile. The centre of the principal façade is occupied by a large gate seventy-five feet in height, being a kind of triumphal arch, surmounted by a rich Doric entablature. The principal entrance is between two colossal groups placed upon granite pedestals, and bearing celestial and terrestrial globes of huge dimensions. Over it is a cupola, surmounted by a lantern, from which a spire rises to the height of eighty-four feet. This spire is covered with the finest ducat gold, and, from its great elevation, catching and reflecting the first and last rays of the sun, exhibits a most brilliant appearance, being visible from every quarter of the metropolis. On either side of this grand entrance the building projects two hundred and fifty feet, with a rusticated basement, surmounted by a running frieze, which contains naval trophies in bas-relief.

The interior plan of this vast building presents many portions of vast interest, which our limits compel us to pass over slightly, or omit noticing. Amongst the most extraordinary in the inner area of 62,300 square feet, are four slips for building men-of-war, in which several of from seventy-four to 110 guns have been constructed. This spot is surrounded by most capacious warehouses, in which are deposited every species of article necessary for the equipment of an extensive and powerful naval armament. Besides the apartment required for officers, and for the residence of the chief officers of the establishment, there are museums, with collections of whatever can be rendered subservient to the naval service, and such curiosities as have been collected in distant countries by Russian navigators. Arms of various kinds both for sea and land service, nautical instruments and models of machinery, models of ships and of boats, maps, charts, and plans of fortified ports, presses for printing, rolling copper-plates, and lithography, and a most copious library of professional books and manuscripts, are amongst the interesting exhibitions of this vast and magnificent building.

Near to the Admiralty there is another edifice of a similar nature, but inferior in extent and splendour of architecture, called the *Etat Major*, or the general staff of the army. In this building all the affairs of the military establishment centre; and the number of clerks, both civil and military, is prodigious. The grand saloon is a splendid apartment, with a cupola, from the centre of which is suspended a magnificent lustre, with thirty gas-burners, which, with four colossal candelabras of bronze, surmounted by the imperial eagle grasping the thunder-bolts, serve to illuminate the apartment. The library, the incombustible hall in which the documents and records of the army are preserved, and the model-rooms and museum, are striking objects in this building.

The castle of St Michael, in which the Emperor Paul was assassinated, and which has never since been occupied by any of the imperial family, is now converted into a military seminary for the education of officers of artillery and engineers. This is a vast building, once strongly fortified, and with an interior so ornamented, that Kotzebue, who saw it in its splendour, compares it with ancient descriptions of the gorgeous palace of Nineveh. The fortifications have, however, now disappeared, and the interior is filled with students in five classes, engaged in pursuits connected with the higher branches of the military art.

The two arsenals, and the foundery upon the banks of the Neva, present the appearance of a vast mass of building of considerable grandeur, and in the style of the Grecian architecture. Amongst every thing that can be useful in the art of war there are preserved some warlike remains of ancient times; amongst which are the rich arms of the Teutonic knights, removed from the arsenal of Riga to St Petersburg after the capture of that city.

The different departments of the executive civil government of the empire, called the Colleges, are appropriate buildings, and one or two of them fine specimens of architecture. The college of foreign affairs, with the residence of the chief, is an elegant structure, as is also that of the college of the interior. The colleges of war, of marine, of justice, and of commerce, have each handsome buildings, and attached to them beautiful residences for their several chiefs.

The post-office is a fine and large building, where not only the conveyance of letters is arranged, but the conveyance of money from one part of the empire to another; and it has the superintendence of the post-horses for the use of travellers at the several stations. The mint is in a fortress situated on a small island on the Neva. This citadel was the first of the erections of Peter the Great. It is furnished with five regular bastions, which range round the island; it is, however, no longer of any use for defence. The coining of money, as so much copper circulates, employs many hands, in spite of the admirable machinery supplied from England to diminish the labour; and the chief manager of the coining at present is a native of our island.

It has certainly been the object of the government of Russia under all its sovereigns to promote the civilization of its subjects by the diffusion of knowledge. Whether that object has been pursued in the right way; whether it has been too much confined to the few in immediate contact with the court, and not sufficiently communicated to the larger class; are questions which need not be discussed here. The means of spreading taste and information have been abundantly furnished to this capital at least. The Imperial Academy of Sciences was founded by Peter, who also established the rudiments of the extensive museums in the elegant building now occupied by that society. Some of the ablest mathematicians of Europe have been professors in it (for instance, Euler and the two Bernoullis), or members of it; and amongst the natives much progress has been made in astronomy, geography, and the other branches of science; whilst great advances have been making in each of the departments of natural history.

In the Academy, also, much has been done by individual members to propagate a knowledge of the national history and philology, of numismatics and Russian antiquities, of statistics and political economy, and in translating, from the French, German, English, and Italian languages, a great number of the most popular works into the Russian language. The astronomical observatory near the Academy, and connected with that institution, is sedulously at work, and publishes its observations. The several museums are all accessible to the public. They are, the zoological museum, the cabinet of mineralogy, the collection of dried plants, the Asiatic museum, the collection of ancient medals and coins, the three cabinets of Asiatic, Russian, and modern medals, and the cabinet of curiosities. To these may be added an extensive and well-selected library.

The Imperial Academy of Arts is one of those establishments to which the government has devoted considerable sums of money. The beauty and extent of the building, and the collections it contains, would entitle it to a fuller description than can be allotted to it in this place. The paintings, casts, and sculptures, are numerous, and many of the first merit. There are more than two hundred students receiving instruction in the different branches of the fine arts in this establishment; and a few at their own expense, amounting to thirty or forty pounds a year, which covers the expense of lodging and subsistence.

The Ecole des Mines attracts attention from its grandeur and its extent, as well as from the arrangement of the different rooms and galleries, and from the various collections illustrative of the mineralogy of all countries. The establishment, as well as the whole mining department, is under the minister of finance; and the students, about three hundred in number, are chiefly educated at the expense of the government, and are called cadets of the mining corps. The pupils, when properly qualified, are distributed amongst the vast mining districts of the empire, where their services are found to be of incalculable value.

But however expensive may have been the means applied to promote knowledge in the higher branches of science, there does not appear to be any appropriation, even in a small degree commensurate, devoted to the elementary kinds of instruction. The university of St Petersburg has but a limited operation, and, indeed, must be considered as imperfect. It has schools connected with it, which are bad specimens of the institutions from which they have been copied, called in France *Ecoles Normales*, or in Germany, Lyceums. It is said preparations have been made for improving the state of general education; and, in the mean time, there are abundance of private tutors, mostly Germans or Swiss, who give lessons by the hour to those youths who need instruction. Amongst the other institutions of St Petersburg connected with instruction, may be noticed those of a benevolent kind, such as a school for the deaf and dumb, schools for the children of soldiers, for the subalterns of the army, for the orphans of the military, and schools for the engineers, artillery, and the marine. Several schools of various descriptions, according to the rank of those who are taught, have been established by the females of the imperial family. Some of these are for the daughters of nobles, and others for burghers.

The only public library in the city is in a fine but scarcely finished building. The books that first formed it were obtained at Warsaw, on the partition of Poland. It is far from being a valuable collection, and is not much resorted to. One of the apartments contains a copy of every book printed in the Russian tongue since the art of typography has been introduced into that country. But the whole number of such works is not more than 15,000, scarcely more than the annual delivery from the printing-presses of Germany. See LIBRARIES.

The churches of the city are very numerous, and are for the most part appropriated to the religious services of the established or orthodox Greek communion, which comprehends about two thirds of the population. The most remarkable of the edifices appertaining to this class of religionists is called the Church of our Lady of Kazan. It is a large and splendid monument of architecture, although scarcely to be considered as of any of the regular orders. It abounds both in beauties and defects. It is in the form of the Greek cross, and the centre has a cupola not exactly in keeping with the columns in the façade; but, on the whole, it is a striking edifice. The interior is decorated with images of saints, and some pictures of no great merit. It has many military trophies in honour of the memory of those Russian heroes who have been interred within its walls, or of such of them as have been buried where they fell, and have been deemed worthy of a cenotaph. Another remarkable church is that of Isaac, built on the foundation of a more ancient temple, and only completed within the last few years. It is in a commanding situation, and of great magnitude, and in architecture somewhat resembles St Peter's at Rome. The form of the church is that of the Greek cross, being 334 feet in length, and 288 in width, including the lateral porticos. In the centre rises a dome, the exterior diameter of which, surrounded by an open peristyle of Ionic columns, measures 105 feet. The total elevation of the edifice, from the level of the square on which it stands, to the ball bearing the cross, is equal to 309 English feet. The interior is ornamented with 188 columns and pilasters of marble, of the Corinthian order. The capitals and the shafts are of bronze, richly gilt. The arched roof, decorated with various compartments, and embellished with every thing that painting, sculpture, and gilding can effect, render the whole not unworthy to rival many of the most distinguished churches of Italy.

Of the other churches, which are numerous, we can only notice one more. It is dedicated to St Paul, and has been the burial-place of the several emperors since that title was assumed. It stands within the citadel, and it has only a single cupola and tower, two hundred and six feet in height. Its lofty and slender spire, with gold glittering in the sun, is a well-known object to the traverser of the most distant parts of the metropolis, and by it he knows the centre of the city. The interior of this temple is remarkable for the simplicity of its decorations; but it is graced with a vast number of standards, batons, staffs, and keys of fortresses, taken from their enemies by the armies of Russia. The churches not named here are numerous, and most of them have domes, which, being of burnished copper, or richly gilded with gold, give an astonishing magnificence to the city as a whole, when viewed from any elevated spot. Besides the established churches, there are many belonging to professors of the Greek religion, not adhering to the orthodox faith. The Roman Catholics have a beautiful church of the Corinthian order, with a fine dome, surmounted with twenty-four elegant pillars. It was made the burial-place of the celebrated General Moreau, who died of the wounds he received near Dresden in the year 1813. A plain white tablet, edged with black marble, marks the last resting-place of the conqueror of Hohenlinden. There are two German churches for the Lutheran worship, which, though deemed excellent specimens of architecture, have few decorations, and nothing in the interior to attract much attention. An English church presents a noble front to the river. The interior is neat and simple, but the altar-piece is a fine painting of the descent from the cross. There is no gallery; and, although capacious, it is not sufficiently large to accommodate the whole of the English residents. The officiating minister has a good residence near the church; and both buildings are exempt from taxes, and from the domiciliary visits of the police.

The hospitals, especially those for the civil inhabitants, are numerous, and some of them are on a gigantic scale. In one of them, Smolnoi, more than 1400 patients are collected. At the Foundling Hospital more than 4000 children are received annually; and there are seldom less than 500 at the breast. Independently of the in-patients, the great hospitals relieve out-patients, the number of which exceeds 30,000 yearly. The empress has the superintendence of the hospitals and other charitable institutions, and is said to show great zeal in adopting any ameliorations in their arrangements that are suggested to her, but only after deliberate examination.

St Petersburg is abundantly supplied with objects for amusement, such as theatres for music, and for the representation of comic and tragic scenes in human life and manners. There are German and French houses in which plays are performed in those languages, and both a German and an Italian opera-house. The places of amusement are in some measure supported at the expense of the government; and thus, though the price of admission is low, the native Russians, excepting a very few who have travelled, seldom partake of them. They have, however, national music of a peculiar character, and several dances unknown in other countries, the enjoyment of which is highly gratifying. The ice-mountains and sledges are purely Russian amusements, and some peculiar athletic exercises, one of which is boxing, but with gloves on the hands, so as to draw no blood, and scarcely to inflict much pain.

All foreigners who have resided at St Petersburg agree that there are few great cities in which the police is conducted with more strictness than there. The public is very well secured. Robberies or murders are seldom heard of, and all thoughts of danger on these heads are wholly banished. At all hours of the night, and in the most unfrequented streets, the passenger passes without annoyance and without apprehension of danger. In each quarter of the city there is a station of the police, with a tower on which a watchman is constantly kept, to give an alarm in case of fire, by flags during day and by lamps at night; and fire-engines, with strong horses, are always ready, with some firemen, in case of need, and repair from every station to the spot where the accident occurs, which is indicated by well-known signals. There is an agent of police resident at each of the stations, who has an office, with several persons under him; he watches over the conduct and behaviour of the inhabitants of the district, preserves order and tranquillity in his quarter or section, and can decide in cases of petty quarrels, if the parties agree to such a course, as is sometimes done at the police-offices in London. There is a lock-up-house, and in some cases an hospital, attached to these police stations. Connected with the police is a corps called street-walkers, in small wooden boxes, in the various streets, at the door of which one always stands armed with a battle-axe. They consist chiefly of old but hale soldiers; and their duty is to prevent all obstructions by carriages, which are vastly numerous, to check the first symptoms of riot or disturbance, and to prevent begging in the street. In this last work they have been eminently successful, as no place in Europe is less distressed by the importunity of mendicants than this city. One of the duties of the street-walkers also is to go round with any new ukase of the emperor from house to house, to make the master of each acquainted with it, and to obtain an acknowledgment of his having read and taken cognizance of its import. It is thus that new laws are quietly promulgated throughout the capital.

One object in this city which has not yet been noticed is the colossal equestrian statue to the memory of Peter the Great. He is represented on a horse at full gallop up a rock, the top of which is a perpendicular precipice, on arriving at which the horse suddenly stops. The action is the moment of the sudden halt at perceiving the danger. It is admirably executed, and, being of prodigious size, excites the highest degree of admiration. (G.)

PETERSFIELD, a borough and market-town of the county of Hants, in the parish of Buriton, and hundred of Finchdean. It was erected into a borough by Queen Elizabeth, and is governed by a mayor and common council. It returned two members to parliament before 1832, but since that year it has elected but one. The market is held on Saturday. It is a place of little trade, except what it derives from being on the road to Portsmouth. The population amounted in 1801 to 1406, in 1811 to 1525, in 1821 to 1752, and in 1831 to 1803.

PETERS LE PORT, a market-town of England, in the island of Guernsey. It is situated on the south-eastern part of the island, and consists of one long, narrow street. It is defended by two ports, one of which, called Castle Cornet, stands on a rock, separated by an arm of the sea from the land, and which commands both the town and the harbour. A pier of vast stones affords protection to the harbour, where there is good anchorage, and whence ships may depart in all states of the weather; and it also forms a pleasant and extended walk. There is some trade with Newfoundland; and formerly there was much smuggling carried on, but that has been stopped by the introduction of a custom-house. The population has much increased of late years, and in 1831 amounted to 5966 males and 7924 females.

PETERSWALDAU, a city of the Prussian government of Reichenbach, in Silesia. It is finely situated, and has a large establishment of the United Brethren. It belongs to the family of Stolberg Wernigerode, and contains 510 houses, with 3080 inhabitants, who carry on extensive cloth manufactories.

PETERWARDEIN, a city of the Hungarian province of the Sclavonic military frontier. It is the capital of the limits of that regiment or circle, extending over 1244 square miles, comprehending four cities and towns, and sixty-one villages, with 91,618 inhabitants. The city is situated on the river Danube, is strongly fortified, and is the head-quarters of the military staff of the district. It contains, including its suburb Bucovetz, 680 houses and 4280 inhabitants. Long. 19. 47. 11. E. Lat. 45. 15. 30. N.

PETHERTON, NORTH, a town of the county of Somerset, in the hundred of the same name, 137 miles from London and three from Bridgewater. It consists of one long street, tolerably built; but the parish is very extensive, comprehending seventeen villages. The population amounted in 1801 to 2346, in 1811 to 2615, in 1821 to 3091, and in 1831 to 3566.

PETHERTON, *South*, a market-town of the county of Somerset, in the hundred of the same name, 137 miles from London. It is situated on the river Parret, which is navigable for barges nearly to the town. There is a small market on Thursday; and there are manufactories of linen. The population amounted in 1801 to 1674, in 1811 to 1867, in 1821 to 2090, and in 1831 to 2294.

PETIT, JOHN, a doctor of the Sorbonne, who very early gained to himself a name by his knowledge, and the eloquent orations which he pronounced before the university of Paris. He was employed in the famous embassy which was sent from France to Rome for the purpose of healing the schism in 1407; but he soon forfeited all the honour which he had acquired. John Sans Peur, duke of Burgundy, having treacherously contrived to assassinate Louis of France, duke of Orleans, only brother to Charles VI., John Petit, entirely devoted to the views of the murderer, maintained in a public disputation, at Paris, on the 8th of March 1408, that the murder was lawful. He had the effrontery to assert, that "it is allowed to employ fraud, treason, and every other method, however base, in order to get rid of a tyrant; and that no faith ought to be kept with him." And he had even the audacity to add, that "the man who should commit such an action, not only deserved to be exempted from punishment, but to receive a reward." This sanguinary doctrine was loudly exclaimed against; but the Duke of Burgundy's powerful influence sheltered Petit for some time. Some eminent writers of that period, however, with Gerson at their head, denounced the doctrine to John de Montaigu, bishop of Paris, who condemned it as heretical, on the 23d of November 1414. It was likewise condemned by the council of Constance the year following, at the instigation of Gerson; but no notice was taken either of Petit's name or of his writings. In fine, the king, on the 16th of September 1416, ordered the parliament of Paris to pronounce a severe decree against this dangerous performance; and it was also censured by the university. But the Duke of Burgundy, in 1418, had interest enough to compel the grand vicars of the bishop of Paris, who then lay sick at St Omer, to retract the sentence which that prelate had passed in 1414. Petit had died three years before this, or in 1411, at Hesdin; and his apology in favour of the Duke of Burgundy, with all the particulars of that infamous transaction, may be seen in the fifth volume of the last edition of Gerson's works. Father Pinchinat, of the order of St Francis, and author of the Dictionary of Heresies, has endeavoured to vindicate his order from a charge brought by some writers, who have called Petit a Cordelier or Franciscan friar. "He proves very clearly," says the Abbé Prevot, "that he was a secular priest;" and adds, that "upon the same evidence, Father Mercier, a Cordelier, had a warm dispute in 1717 with M. Dupin, who had given this title to Petit in his Collection of Censures. He represented to him," says he, "before a meeting of the faculty, the falsity of such a claim, and the injury which he offered to the order of St Francis. Dupin, convinced of his error, candidly owned that he was led into it by following some infidel writers; and promised to retract it in the new edition of the Censures, which was published in 1720. M. Fleury, who had committed the same mistake, promised also to make amends for it by a solemn recantation; but dying before he had an opportunity of doing that piece of justice to the Cordeliers, the continuator of his Ecclesiastical History, who had not such opportunities of information, fell into the same fault." (*Pour et Contre*, tom. x. p. 23.) If we follow L'Avocat's Dictionary, it would appear that no fault was committed; for it gives a list of the pensioners of the dukes of Burgundy, in order to prove that John Petit was a Cordelier. Indeed it is highly probable, that if Dupin, Fleury, and Father Fabré, did not alter their opinion, it was owing to a firm persuasion that they had committed no error.

PETITIO PRINCIPII, in *Logic*, is the assuming a thing as true, and drawing conclusions from it on this assumption, when it is either really false, or at least requires to be proved before any inference can be drawn from it.

PETIVER, James, a celebrated English botanist, contemporary with Plukenet. Of the precise time of his birth no notice has been preserved. He was by profession an apothecary, having served an apprenticeship under Mr Feltham, apothecary to St Bartholomew's Hospital. He settled in Aldersgate Street, where he commenced business on his own account, which he continued during the whole of his life. His business was extensive, and he afterwards became apothecary to the Charter-house. Excepting Sir Hans Sloane and Mr Courten, he was the only person after the Tradescants who made any important collections in natural history, previously to those of the present day. He employed the captains and surgeons of different ships to bring him home specimens; and by means of printed directions he enabled them to select proper objects. In this manner his collection soon became so valuable, that, some time previously to his decease, he was offered L.4000 for it by Sir Hans Sloane, by whom it was purchased some time after Petiver's death. Both at home and abroad his fame was extended by his valuable museum. He was chosen a fellow of the Royal Society; and having become acquainted with Ray, he assisted him in arranging the second volume of his History of Plants. He died on the 20th of April 1718; and his funeral was honoured by the attendance of Sir Hans Sloane, and other eminent men, as pall-bearers.

He published several works on different subjects of natural history, particularly, 1. Musci Petiveriani Centuriæ decem, 1692–1703, 8vo; 2. Gazophylacii Naturæ et Artis, Decades decem, 1702, folio, with a hundred plates; 3. A Catalogue of Mr Ray's English Herbal, illustrated with figures, 1713, and continued in 1715, folio; 4. Many small publications, which may be found enumerated in Dr Pultney's book; 5. Many papers in the Philosophical Transactions, and a valuable article in the third volume of Ray's work, entitled Plantæ Rariores Chinenses, Madras-patanæ et Africanæ, a Jacobo Petivero ad opus consummandum collatæ. Many of his small tracts having become scarce, his works were collected and published, exclusively of his papers in the Transactions, 1764, in two vols. folio.

PETLAD, a town of Hindustan, in the province of Gujerat, and district of Broach. It is sixteen miles north-east from Cambay. The inhabitants are here subjected to the servitude of acting as guides to travellers, from which only a certain caste, the Dhers, are exempted. Long. 73. E. Lat. 22. 27. N.

PETLAHWAD, a town of Hindustan, belonging to the Mahrattas, in the province of Malwah. It is seventy miles west by north from Oojain. Long. 74. 50. E. Lat. 23. 22. N.

PETRARCH, Francis, one of the greatest poets and most celebrated men of whom Italy can boast, was born at Arezzo on the 20th of July 1304. He saw the light amidst the rage of contending factions. His father, the friend of Dante, and, like him, of the Ghibelin party, had been banished from Florence, where he filled a respectable situation confided to him by the republic; and having taken refuge in Pisa, he committed the primary tuition of his son, then in his seventh year, to an old grammarian of that city named Convennole da Prato. Two years afterwards, when the death of the Emperor Henry VII. had destroyed the hopes of the Ghibelins, the father of Petrarch removed his family to Avignon, whither Clement V. had transferred the pontifical court, and his son resumed his studies at Carpentras, under his former master. It was then that the youthful pupil of Convennole visited for the first time the fountain of Vaucluse; and the rural beauties of this celebrated spot left an indelible impression upon his mind. In that age, the study of law was almost the only pursuit that led to fortune. Petrarch accordingly passed four years at the university of Montpellier, where, instead of immersing himself in the hazy erudition of the schools, he devoted his days and his nights to Cicero and to Virgil. At the same time he made himself familiar with the compositions of the troubadours, and, if we may credit Gariel, in his *Idea of Montpellier*, retouched the romance of *Pierre de Provence et la belle Maguelone*, written in 1178 by the canon Bernard de Triviés. But whilst engaged in these seducing pursuits, he was disturbed by the arrival of his father, who, greatly incensed at what he conceived to be a gross misapplication of time, consigned to the flames the little library of his son, and was with difficulty induced to restore to him Cicero and Virgil, after they had been half consumed. Being now sent to the university of Bologna, to receive the instructions of John d'Andrea, the most learned canonist of that age, Petrarch soon formed a connection there with Cino de Pistoia, a Florentine, like himself, whom Bartolo cites as his master in the science of law, and who deserved to become that of Petrarch and Boccacio in poetry. If the young legist did not long retain the lessons of the jurisconsult, he at least remembered those of the poet; and at a later period he did not disdain to consecrate to the memory of Laura several verses borrowed from the bard of Selvagia. At the age of twenty-two he lost his father, and being ruined by faithless tutors, he returned to Avignon, where he took up his residence, appeared with distinction in the most brilliant society, and found himself at liberty to apply to his favourite pursuits. The mathematics, which were then in their infancy, history and antiquities, philosophy with its innumerable systems, especially those which related to the science of ethics, occupied, each in its turn, a mind thirsting for knowledge. The first poetical attempts of Petrarch, like those of Dante, were made in the Latin language; but, happily, his muse soon ventured to confide her inspirations to the vulgar tongue, the only one, besides, which the women understood.

About this time, he renewed his acquaintance with one of his school companions, James Colonna, the youngest son of Stephen Colonna, the head of the illustrious family of that name. By the elevation of his mind, and his passion for letters, this young Roman was every way worthy to become the friend of Petrarch, and he continued to be so until the period of his death. Cardinal John Colonna, the eldest brother of James, desired also to share the friendship of Petrarch; and, in the society of these eminent individuals, the poet became known to the most illustrious strangers who visited the pontifical city; whilst the noble frankness of his manner, his mild yet sprightly physiognomy, the graces of his mind, and his unaffected anxiety to please, secured him a remarkable ascendency in this select circle. Colonna, the father, took a particular pleasure in recounting to him the events of his life, as well as in developing his projects; and it was in these conversations that Petrarch imbibed a new love of Italy, and a stronger aversion for every thing calculated to prolong its misfortunes or to obscure its glory. When James Colonna was called to the bishopric of Lombez, his friend accompanied him to his diocese, and in their way they stopped at Toulouse, where, a few years before (in 1324), Arnauld Vidal had been honoured with the poetical eglantine. The seven Maintainers of the gay Science were then beginning to diffuse a taste for the vulgar poetry, and to bring into notice those little effusions of song unknown to the ancients, and some of which have still remained peculiar to the literature of the troubadours. A submissive and unfortunate lover, Petrarch, like them, sought to console himself by singing at once the charms and the cruelty of his beloved. On the 6th of April 1327, on holy Monday, at six o'clock in the morning, he had seen, in a church of Avignon, the daughter of Audibert de Novis; and the passion he conceived for this lady occupied the remainder of his life, over which it diffused an air of poetry and romance. Laura was united to Hugues de Sade, a young patrician, and a native of Avignon; but, faithful to her duties as a wife and a mother, she forbade Petrarch to indulge the slightest hope. Incessantly haunted with this beautiful vision, the poet visited in succession the south of France, Paris, and the Low Countries; the forest of the Ardennes re-echoed in turn his verses and his lamentations; he traversed Burgundy, the Lyonnais, Dauphiné, and, after an exile of eight months, returned to bury himself in the delightful solitude of Vaucluse.

Pope John XXII. was then meditating a new crusade, and, to further his object, he led the Romans to hope that he would re-establish the chair of St Peter in Italy. This double project excited the imagination of Petrarch, and inspired his beautiful ode to the Bishop of Lombez, *O aspettata in ciel*, &c. The following year, 1335, we find him expressing, in beautiful Latin verses addressed to Benedict XII. his earnest desire to see the Holy See re-established in the eternal city; and to this patriotic aspiration the pope replied by appointing him canon of Lombez, with the hopes of a prebend. The same year was marked by an event unique in the life of Petrarch. A recent and close connection attached him to the interests of Azon de Corregio, one of the principal lords of Italy, who was then prosecuted before the papal courts at the instance of the family of the Rossi. In the hope of serving his friend, the poet resolved to plead his cause at the bar; and this he did with so eminent success, that it proved to both a day of triumph. Since he had first beheld Laura, he sought occupation everywhere, without being able to fix himself anywhere. A vague disquietude of mind led him to visit Rome, where, however, the friendship of the Colonnas could not detain him; and he returned to Avignon, from which, although he had no desire to establish himself in that city, he could not for any length of time stay away. Finding himself in this unsettled state of mind, he now shut himself up in his retreat at Vaucluse, without friends and without domestics, as if solitude could have extinguished a passion which increased in spite of all his efforts to subdue it. The country-house of the Bishop of Cavaillon adjoined that which he occupied. This prelate was Philip de Cabassole, whom the poet himself calls a little bishop and a great man. Petrarch could not refuse his consolations, and soon reckoned the good bishop amongst his friends.

About this time the lover of Laura seems to have been occupied with a great literary conception. He had commenced writing in Latin the history of Rome from the foundation of the city to the reign of Titus. But in collecting materials for this work, he was much struck with the grandeur of the events which had marked the termination of the second Punic war; and suddenly conceived the design of giving to his age a regular epic, of which Scipio should be the hero. His plan was hastily traced; some portions of the projected poem were written under the first access of inspiration; and, before the end of the year, the poet was in a condition to submit to his friends the greater part of his work, which they received with the most flattering encomiums, and, having exhausted the language of eulogy, styled the author *sublime* and *divine*. But a more grateful distinction awaited him. His sonnets and his *Canzoni* had filled France and Italy with the name of Laura and that of her lover; in fact, these pieces were universally read and admired. Of the impression produced by his poetical genius he had soon the most convincing evidence. On the 23d of August 1340, he received at Vaucluse two letters, one from the Roman senate, which invited him to accept the poetical laurel, and be crowned in the capitol, and the other from the chancellor of the University of Paris, which offered him the same triumph. It is a mistake, however, to give the credit of this proceeding to the learned corporation here mentioned. The most careful researches made in the registers have not detected a single trace of the deliberation which must necessarily have preceded the transmission of such a letter as that written by the chancellor; and every thing inclines us to believe that Robert de Barde, who then held that office, a Florentine, and the personal friend of Petrarch, had written him without consulting his colleagues, trusting to inspire them with his own admiration, whenever the poet should appear in Paris. The choice of Petrarch, however, was already made. He had long coveted the poetic laurel, and even made known his wishes to Robert of Anjou, king of Naples, whose influence had stimulated the admiration, and hastened the decision, of the Roman senators. This prince cultivated letters with enthusiasm, and protected them in a manner worthy of a king. Wishing to appear indebted to him for the crown which had been offered to him, Petrarch embarked for Naples, carrying with him his epic poem, which he had entitled *Africa*. The king and the poet had repeated conferences upon the subjects of poetry and history; but not thinking these sufficient, the latter demanded a more rigorous trial of his qualifications and acquirements, and offered to reply, during three days, to all the questions that might be proposed to him upon history, literature, and philosophy. In this public examination he acquitted himself to the admiration of all. Robert solemnly declared him worthy of the promised triumph; and at his audience of leave, the king, divesting himself of his robe, put it on Petrarch, at the same time requesting him to wear it on the day when he was to receive the laurel crown.

He then repaired to Rome, and, on Easter-day (the 8th of April 1341), ascended the capitol, in the midst of the principal citizens, preceded by twelve youths selected from the most illustrious families, who declaimed his verses. After a short harangue he received the crown from the hands of the senator Orso, count de l'Anguillara, and then recited a sonnet upon the heroes of ancient Rome, whose place he then appeared to occupy. Descending from the capitol, he was conducted, by the same cortège, amidst the acclamations of a crowd eager to witness so novel a spectacle, to the church of St Peter, where he deposited on the altar the laurel which encircled his brow; after which he set out for Avignon by land, as if to enjoy more leisurely his renown. He carried with him the title of almoner to the king of Naples, and letters-patent giving him, as well by the authority of King Robert as by that of the senate and people of Rome, full and free permission to read, vindicate, and explain the ancient books, to make new ones, compose poems, and on every occasion to wear the crown of laurel, ivy, or myrtle, at his pleasure.

Azon de Corregio having just usurped the sovereignty of Parma, on the pretext of freeing it from thraldom, urgently pressed Petrarch to spend some time with him; and, captivated by the attentions paid to him, the poet soon accepted the situation of archdeacon of the church of Parma, caused a house to be built there, and then employed himself in completing his poem of *Africa*. Glory had now begun to console him for his labour and anxiety, when envy, awakened by unexampled success, attempted to disturb his repose; and at the same time the hand of death had stricken the Bishop of Lombez, his best friend and warmest admirer. The accession of Clement VI. to the triple crown, in 1342, revived in the mind of Petrarch hopes which had already been twice disappointed. At the request of the Romans, he accompanied to Avignon the deputation they had sent for the purpose of soliciting the new pope to fulfil the promises made by John XXII., and, in this matter, he acted as the organ of the deputation. The pontiff received him with marked distinction, appointed him prior of Migliorino, in the diocese of Parma, and treated him with the greatest familiarity, but made no answer to the petition of the deputation, beseeching him to remove to Italy. At the same time, however, his holiness, anxious to testify the confidence he reposed in Petrarch, intrusted him with a delicate mission, namely, that of obtaining from the regency of Naples a recognition of the rights of the Holy See, during the minority of Jane, granddaughter of King Robert. The young queen conversed several times with Petrarch, who, besides, received public testimony of the esteem she entertained for letters; but the candour of the poetical negotiator rendered him the most unfit person in the world to control the selfish policy of the councillors by whom that princess was governed. He fled with horror from a barbarous and corrupt court, which sought relaxation from its debaucheries, in the depraving spectacle of gladiatorial combats. He crossed the Apennines, made no stay at Parma, and, eager to escape from Italy, then a prey to all the fury of contending factions, he returned to his beloved retreat at Vaucluse, where he remained several months. But a circumstance occurred which soon recalled him to Italy. Rienzi, having made himself master of Rome, cited kings to appear before him, and loudly proclaimed that his fellow-citizens were about to resume, in the fourteenth century, their ancient dominion over the world. All the illusions of Petrarch immediately brightened into realities. An ardent defender of the tribune even in the midst of the pontifical court, he now felicitated the popular leader on his success, exhorted him to persevere, and, impatient to counsel him on the spot, set out immediately for Italy. The news of the massacre of the Colonnas reached him at Genoa, and struck him with consternation; but still he felt disposed to pardon Rienzi, provided Rome had become republican. The sway of the tribune, however, was short-lived, and with his fall disappeared that wild phantom of liberty which had deceived Petrarch.

Scarcely a year had elapsed when the poet had to bewail a loss still more painful. Laura was no more. The pestilence of 1348, which Boccacio has described with such terrible truth, and which desolated all Europe, had carried her off on the 6th of April that year, on the same day, in the same month, and at the same hour, in which her lover had seen her for the first time. The last half of the *Canzoniere* is an immortal monument of the long regret of Petrarch. But although his verses had not made us aware of the sincerity of his grief for his mistress, the touching note which he inscribed upon his copy of Virgil would still attest the profane homage which he paid to her memory.[1] Yielding to the repeated instances of Luigi Conrado, lord of Mantua, Petrarch now repaired to his princely residence, in the hope of finding consolation in the native country of the most sensitive and affecting of all poets; and it was during his stay there that he addressed to the Emperor Charles IV. an eloquent letter, in which he exhorted him to restore peace to Italy. The publication of the jubilee in 1350 drew almost all Christian Europe to Rome. Petrarch, participating in this pious impulse, set out for Rome, and in passing through Florence, visited Boccacio, one of those whom he had particularly noticed at the court of Naples, and who now became his friend. At Rome he found the jubilee commenced, and this grand and consoling solemnity made a deep impression on his mind. His habits became more grave, his manners more austere; and from this time his thoughts assumed a character of severity, the impress of which is visible in his later compositions. At the same time he everywhere received honours which had never before been bestowed on any private individual. The principal citizens of Arezzo conducted him with pride to the house where he was born, assuring him that nothing had been changed in it; and, in fact, the town had obliged the proprietors, into whose hands this house had passed, to pay the most religious respect to the place consecrated by his birth.

The friendship of the Carraras having induced Petrarch to visit Padua, he had scarcely arrived when Boccacio came to announce to him, in the name of the senate of Florence, that he had been re-established in his rights as a citizen, as well as in the patrimony of his family, and also to offer him the directorship of the university recently founded in the first city of Tuscany. This honourable appointment, however, had no attraction for Petrarch. His books awaited him in his transalpine Parnassus, as he called Vaucluse; and his cisalpine Parnassus was his house at Parma. He accordingly declined accepting the proffered appointment, and hastened to bury himself in his favourite retreat. At this time Rome, filled with robberies and assassinations, occupied all the pontifical solicitude, with a view to repress these disorders; and Clement VI. invoked the counsels of Petrarch respecting the measures most proper to be adopted. Petrarch, however, replied like a poet rather than a counsellor. He spoke of the ancient rights of the Roman people, of excluding strangers from public offices, of restoring to the senate its dignity, and declared that he saw no safety except in the establishment of the republic upon the principles of equality and justice. About the same time, Rienzi, having fallen into the hands of the emperor, was delivered up to the pope, and brought before a judicial commission, against the legality of which he vehemently protested. It is said that Petrarch wrote to the Roman people, warmly exhorting them to interpose in favour of his old friend; and, in fact, this exhortation is found in his works. But there is nothing to show that it was sent according to its address; on the contrary, almost every circumstance leads us to believe that his imagination alone had prompted him to write this letter, rather to console than to save Rienzi. Nevertheless, from a superstition indicative at once of the ignorance and the knowledge of a semi-barbarous age, those judges, so impatient to punish a factious chief whom they believed unworthy of the ordinary benefit of the law, hesitated as soon as they learned that he was a poet, and feared to condemn a man belonging to an order which Cicero had pronounced "sacred." But the peril of the modern Gracchus was not the only vexation which Petrarch experienced. The physicians by whom the pope was surrounded, and whose ridiculous ignorance he had denounced to the holy father, combined against him. To suppose himself wounded by arrows which fell short of their mark, was no doubt an error on the part of the poet, and, under its influence, he humbled himself so far as to borrow the arms of his adversaries, in order to repel their attacks.

On his return to Vaucluse, that tranquil retreat inspired him with an answer more worthy of himself. This was his Epistle to Posterity, in which he gives an account of the principal events of his life, until his departure from Italy, about the middle of the year 1351.[2] Some months afterwards, Innocent VI. was called to the government of the church; a man of an irreproachable life, but of little knowledge, and the only pontiff from whom Petrarch did not receive some mark of favour. The poet, after having twice, under Clement IV. refused the office of apostolical secretary, was now suspected of magic by his successor, and he took no pains to dispel the prejudices of the new pontiff. His regret for Italy was only increased; and he repassed the Alps, uncertain where to fix his abode, although prepared to adopt as his country any place where he might live in tranquillity and independence. He had long wished to visit Milan, and, on this occasion, he proceeded no farther. Charmed with the reception he met with from a man of power, who knew well how to exhibit himself to the poet in an amiable light, and admitted to the counsels of John Visconti, Petrarch accepted a mission having for its object to bring about a reconciliation between the republic of Genoa, which had just given itself up to Visconti, and that of Venice, elated by recent and apparently decisive successes. Three years before, Petrarch had endeavoured to prevent a war which presaged long and bloody divisions in Italy. Connected with the Doge Andrea Dandolo, one of the greatest men of this age, in politics, in war, and in letters, the poet appealed to the patriotism of his friend, and the latter replied by praising the eloquence of Petrarch, but without deferring to his counsels. Hence this new attempt proved not more fortunate than the previous one; but events soon showed on which side lay the want of foresight. Venice was reduced to the necessity of purchasing peace; Dandolo died of grief, and Visconti survived him little more than a month. Nevertheless, after a silence of three years, the emperor replied to the letter in which Petrarch had called upon him to restore peace to his country, an appeal which he had several times renewed. But the avarice of Charles IV. furnished a more powerful motive to appear in Lombardy than the patriotic addresses of Petrarch. By his orders, the poet proceeded to meet him at Mantua, full of confidence in his wisdom, and hoping that, as the friend of the Holy See, he would for ever banish from Italy the names of Guelf and Ghibelin, which had caused the effusion of so much blood, and fomented such fierce animosities. But in this monarch he discovered only a weak and avaricious prince, who mistook treachery for talent, and exhibited the strange spectacle of an emperor of Germany in the pay of the Venetians. The poet presented him with some rare and valuable medals of Augustus, of Trajan, and the Antonines. "These," said he, "are the great men whose place you occupy, and who ought to be your models." During eight days which he spent in familiar intercourse with the emperor, Petrarch discovered the mean, narrow, and grovelling character of his mind, and refused to enter Rome in his train, or to be a witness of his coronation. He then attached himself more than ever to the nephews of John Visconti, whom the emperor had loudly menaced, with the view of enhancing the price to be afterwards exacted for confirming them in the usurpations of their uncle. At this period, the public hatred had accused them of fratricide. Petrarch, afflicted with a rumour which he could not believe, repaired to Pavia, where he was employed by Galeas, a friend of letters, to dissuade Charles IV. from undertaking a new expedition beyond the Alps. This embassy proved more successful than the former, apparently because the proceedings of the malcontents in Germany had produced a change in the versatile policy of the emperor. On his return to Milan, the ambassador received from him the diploma of Count Palatine, in a gold box of considerable value. Petrarch accepted this new honour, but returned the box to the chancellor of the empire.

---

[1] The authenticity of this note is still disputed by those who wish to overturn the whole history of Laura. Mr Whyte, a learned Englishman, who discovered at Florence an inedited life of Petrarch, written soon after his death, by Luigi Peruzzi, who had known him, also rejects the evidence of this note. But it is written in a tone which ought to silence incredulity, because feigned emotions never bear the stamp of nature and reality. The Virgil of Petrarch has long been in the royal collection at Paris.

[2] Ginguené (*Histoire Littéraire d'Italie*, tom. ii. p. 582) shows, contrary to the opinion of Badelli, that the Epistle to Posterity was written in 1352, and not in 1372.

Fatigued with the agitation of courts, the poet now fixed upon a new retreat on the banks of the river Adda, in a pretty country-house, which he called Linterno, in honour of his hero Scipio. Literary projects and researches, religious exercises, and frequent visits to the charterhouse of Milan, now occupied his leisure. All the great lords of Italy had disputed with pontiffs and kings the honour of his presence and conversation. But a goldsmith of Bergamo, named Capra, solicited and obtained a sort of preference. At the approach of Petrarch all Bergamo went out to meet him, whilst Capra received him with a magnificence almost royal, and proved by his enthusiasm, not less than by the number and quality of his books, that he was worthy of his guest. In 1360 a new diplomatic mission led Petrarch to France, whither he went to compliment King John on the recovery of his liberty; and this prince, who had formerly made vain attempts to prevent his return to Italy, now renewed his efforts to retain him. But the envoy of Galeas returned to Milan, without suffering himself to be moved either by the presents of the monarch or by the entreaties of the dauphin; and those of the emperor, backed by the transmission of a gold cup of curious workmanship, found him equally inflexible. But never had a residence in Italy presented fewer attractions. The foreign companies who infested that land of discord, forced him to seek an asylum at Padua, whence he was soon afterwards expelled by the pestilence. He proceeded to Venice, accompanied with his books, which he always carried along with him, and, on his arrival, he presented his library to that hospitable republic, by a writing dated in 1362, on condition that so rare a collection should neither be divided nor sold. By a decree of the senate, a palace was assigned for the reception of Petrarch and his books; and it is, doubtless, this circumstance which has made him be regarded as the original founder of the celebrated library of St Mark.[1] The Abbé de Sade is therefore mistaken in supposing that all these manuscripts had perished. Tomasini, who made a search for them in the year 1635, discovered them in a small dark chamber, situated near the four bronze horses; and there they remained until the year 1739, when permission was at length given to the public to consult them.[2]

This residence at Venice, indeed, is doubly memorable in the life of Petrarch. It was here that, when driven by the plague from Florence, Boccacio came to share his asylum, and presented to him Leontius Pilatus of Thessalonica, who was then teaching him Greek. The lover of Laura had formerly studied that language under Barlaam, a monk, the ambassador of the Emperor Andronicus to Benedict XII., but he had studied it only in the dialogues of Plato; and, from the short stay of the monk at the court of Avignon, there is some reason to believe that, under Barlaam, he learned more Platonism than Greek. But however this may have been, he availed himself of the opportunity thus afforded him to resume the study of that language; and though now past sixty, he found, even in the difficulties which opposed his progress, sufficient enjoyment to mitigate the affliction caused by the loss of many valued friends. It was the fortune of Petrarch to survive all those whom he loved. In the course of fifteen years, death had deprived him of Cardinal John Colonna, James of Carrara, lord of Padua, and several other friends who were not less dear to him, but who are now less known; and this second pestilence bereft him of almost all those who remained, particularly of Azon de Corregio, and two other gentlemen who had shared with him the friendship of the Bishop of Lombez, and who are so often mentioned in his letters under the names of Lælius and Scipio. His grief was profound, and, under the depression it occasioned, he became more sensitive to the criticisms which, notwithstanding his reputation, were freely made on his Latin eclogues, and on some parts of his *Africa*. It was then that the poet wept over his laurels, and, in the bitterness of a wounded spirit, confessed that his crown had been to him a crown of thorns.

[1] Morelli, *Della Publica Libreria di S. Marco*, p. 4 et seq. Venice, 1774, in 4to.

[2] Several of these books, which had lain forgotten for nearly three centuries, fell to dust when touched, and others were found, as it were, petrified. Tomasini, in his *Petrarcha Redivivus* (p. 65), gives a list of those which, in 1635, were found in good condition. Amongst these he remarked a Polyglot Vocabulary in Latin, Persian, and Turkish (*Comanicum*), written in the year 1303, of which he transcribed a small specimen.

Morelli, in the work already referred to, gives a detail of several of these manuscripts, which are still to be seen in the library of St Mark, and accounts for the oblivion into which they had been allowed to fall during so long a period, from the enthusiasm which the acquisition of the Greek manuscripts of Cardinal Bessarion excited in the fifteenth century.

The homage which was paid to him at Venice might, however, have afforded him some consolation, had not a new revolt in the island of Candia created serious alarm in the mother country. The senate, confiding in the military reputation and experience of Luchino del Verme, a Milanese general, the friend of Petrarch, appointed him to the command of the expedition fitted out against the rebels; and the poet consented to support the application made by the doge to that officer. Luchino put down the insurrection; and Petrarch had a place assigned him, on the right hand of the doge, at the equestrian games which were celebrated, in the manner of the ancients, in honour of this victory. Urban V., a virtuous and enlightened pontiff, now attempted to recall the poet to his court, by conferring upon him a canonship at Carpentras; a favour which he repaid by urging the holy father, in a long and vehement letter, to put an end to celibacy in the Roman Catholic church. Meanwhile, the cry of hatred raised everywhere against the Visconti had armed against them the new pontiff, and with him the half of Italy, now menaced by their ambition. Much less alarmed at this danger, however, than apprehensive of a war which would expose his country to the ravages of a foreign soldiery, Petrarch was employed by Galeas Visconti to endeavour to avert the storm; and this, which proved the last, was also the most fruitless of all his missions. But the warmth with which he defended the Visconti family in no degree diminished the favour he enjoyed at Rome. Urban wished to see him; and Petrarch was preparing to respond to an invitation conceived in terms the most urgent and flattering, when he was seized with a terrible malady at Ferrara. But though saved by the care of the Este family, who governed that country, he did not recover sufficient strength to continue his journey; and having returned to Padua, reclining upon a couch in a boat, he established himself four leagues from that city, at the village of Arqua, situated in the Euganean hills, so celebrated by the Romans for the salubrity of the air, the richness of the pasturages, and the beauty of the orchards. There the poet resumed, with his labours, all the imprudence of his usual course of life. Employing at once as many as five secretaries, he exhausted himself with austerities, restricted himself to a single repast composed of fruits or pulse, abstained from wine, fasted often, and, on days of abstinence, allowed himself only bread and water. An unforeseen event also served to retard his convalescence. Urban V., preferring the peaceful abode of Avignon to the tumultuous agitations of Rome, had returned to die in France. He was succeeded by Gregory XI., who, equally well affected towards Petrarch, chose, as his legate in Italy, Philip de Cabassole, now cardinal and archbishop of Jerusalem. But this prelate died soon after reaching Perugia, and Petrarch never more beheld the beloved friend of his youth. The poet, however, appeared to revive on receiving a libel published by a French monk against his letter of congratulation to Pope Urban, and he once more humbled himself so far as to reply to an invective by abuse.

Francesco de Carrara, abandoned by his allies, had just concluded a humiliating peace with Venice. Being obliged to send his son to ask pardon and swear fidelity to the republic, he entreated Petrarch to accompany the youth, and address the senate in his behalf. Though sick and old, the poet only recollected his ancient friendship for the lords of Padua, and repaired with young Carrara to Venice. The day after their arrival they had an audience; but the old man, overcome with fatigue, and perhaps awed by the majesty of the assembly, could not utter a word. The following day, however, he took courage, and his harangue was warmly applauded. But this effort proved his last; it was the song of the swan when dying. He returned to Arqua, feeble, exhausted, and as indocile to the counsels of physicians as ever. Boccacio, who now seemed to supply the place of all the friends he had lost, having sent him the Decameron, which had just been completed, Petrarch read it with enthusiasm; got by heart the novel of Griseldis, which he translated into Latin; and transmitted to Boccacio this version, accompanied with a letter, which appears to have been the last he ever wrote. On the 18th of July 1374, he was found dead in his library, with his head resting upon an open book, an attack of apoplexy having seized him in that attitude. All Padua came to assist at his obsequies. Francesco de Carrara conducted the funeral ceremonies, attended by the nobility and the people; and the family of the poet caused a mausoleum of marble to be erected to his memory before the gate of the church of Arqua.[1]

The illustrious subject of this notice was connected with all the celebrated men of the fourteenth century; he took part in almost every event by which that memorable age was distinguished; and in a life so full of trouble and agitation, the only reproach which he incurred constitutes

---

[1] This simple narrative will enable the reader to appreciate the truth and beauty of the following exquisite stanzas in the fourth canto of *Childe Harold:*

There is a tomb in Arqua; rear'd in air,
Pillar'd in their sarcophagus, repose
The bones of Laura's lover: here repair
Many familiar with his well sung woes,
The pilgrims of his genius. He arose
To raise a language, and his land reclaim
From the dull yoke of her barbaric foes:
Watering the tree which bears his lady's name
With his melodious tears, he gave himself to fame.

They keep his dust in Arqua, where he died;
The mountain village where his latter days
Went down the vale of years; and 'tis their pride—
An honest pride—and let it be their praise,
To offer to the passing stranger's gaze
His mansion and his sepulchre, both plain
And venerably simple, such as raise
A feeling more accordant with his strain
Than if a pyramid form'd his monumental fane.

On the subject of Petrarch's love, which Gibbon calls "a metaphysical passion for a nymph so shadowy, that her existence has been questioned," and also in regard to the last circumstances in the life of the poet, the reader will find some curious information in those of the notes to this canto which refer to the stanzas above quoted.

the finest eulogium on his character. He was born a poet, and always continued so, in his studies, his political missions, his love, his conversation, and his letters. The love of his country was no doubt in him little more than a poetical dream, but it was the dream of his whole life. In the intoxication of glory, as well as in the midst of the most cruel afflictions, ancient Italy was ever present to his thoughts. In the glorious recollections of the past he sought to console himself for the disorders of his own age, and from his worship of antiquity he derived generous inspirations and innocent illusions. That these illusions sometimes misled him in the choice of his friends, cannot reasonably be questioned. His candour exposed him without defence to the calculations of an astute policy, which, masking its real designs under the captivating name of Italy, completed the deception by the interested benefits which it conferred upon letters; but he passed through the courts of the petty Italian tyrants without any one having impeached his character, or cast a shade of suspicion on his memory. His morals were not entirely pure, but they were never corrupt. In his youth he had a natural daughter, near whom he died soon after her marriage; and his son, whom he survived, was cherished with an affection and bewailed with a sorrow that long served to keep alive the regret which the remembrance of his weaknesses had left in his mind. The lover of Laura was impressed with a deep sense of religion; and, amongst the habits of a simple and studious life, it is related that he rose regularly at midnight for prayer. Superior to the pedantry which then and long afterwards clung to learning, this great poet was also an amiable man. His conversation was confiding and animated; his manners were frank and polished. His soul, ardent, but open to all the gentler affections, had a natural craving for friendship, which was to him a necessary of life; and he had many friends, all of whom appear to have been faithful to him, and equally swayed by the double authority of his counsel and his example. Boccacio, whose benefactor he had been, and who had previously been little else than a man of pleasure, became irreproachable, if not austere, in his morals, after his acquaintance with Petrarch. Acciaiuoli, grand seneschal of Naples, having become embroiled with another friend of Petrarch, the latter wrote to both a letter which was only to be opened and read in common, and the consequence was, that they parted mutually reconciled. It was by means of his friends that Petrarch exercised a kind of literary dictatorship in France, in Spain, and in England; it was through his friends that he was enabled to carry on that European correspondence which everywhere rekindled the study and admiration of the ancients. This long supremacy, scarcely disturbed by some clamours which envy had excited, and the honours paid to his memory throughout all Italy, gave a general impulse to the minds of men. He represented in his own person the republic of letters, and his life forms a grand epoch in their history. The elevation of his character made them be respected by the great; whilst his writings contributed powerfully to purify them from that strange alloy with which ignorance had debased them.

He studied with diligence alchemy, astrology, scholastic theology, and Aristotle, with his interpreter Averroes, who had then even more authority than the great master before whom philosophy is said to have stood dumb. Even at the time when, by his advice, Galeas Visconti founded the university of Pavia, he himself directed the course of study, and formed the mind of Malpighino, who afterwards became so famous amongst the restorers of letters by the name of John of Ravenna. His letters *De Scriptis Veterum Indagandis* and *De Libris Ciceronis* attest the extent of the researches he made to recover manuscripts of the ancient authors, which he then copied with his own hand, not venturing to intrust them to the ignorance of vulgar scribes. It was thus that he restored to the literary world the Oratorical Institutions of Quinctilian, though incomplete and mutilated, and the letters of Cicero, the manuscript of which is preserved in the Laurentian Library at Florence, with the copy which he had made from it. He equally recovered some of Cicero's orations which had been lost; and it is further known that he had preserved the famous treatise *De Gloria;* but having lent it to his master Convennole, this old man sold it for subsistence, and Petrarch afterwards attempted in vain to trace it out, as well as the Antiquities of Varro, which he had seen in his youth, and a book of letters and epigrams ascribed to Augustus. It was he also who first made Sophocles known in Italy; and his avidity for manuscripts had become so generally understood, that he received from Constantinople a complete copy of the poems of Homer, without having even asked for it. After the gift which he made to Venice, as already mentioned, he lost no time in forming another library. In an age when chronology and geography were still unknown, he had made a chronological collection of imperial medals, and got together a very considerable number of geographical charts. He himself was the author of a map of Italy, which continued to be consulted a century after his death; and all his biographers have mentioned his researches respecting the island of Thule. In a word, his name, which is inseparable from those of Dante and Boccacio, would alone be sufficient to refute the assertion, too often repeated, that the revival of letters was a consequence of the capture of Constantinople by the Turks in the year 1453.

It is no doubt true, that the rest of Europe did not then possess men who had attained the same splendour and universality of fame. France, which had received from her troubadours the oldest modern literature, could only boast of a few learned men; such as Nicolas Oresme, who enjoyed the esteem of Petrarch, but is better known by his translations, and by a discourse in which he denounced to the pope himself the scandals of the pontifical court; and Pierre Berchoire, author of a kind of encyclopædia, compiled in the spirit and style of the schools, and which he appears to have composed at Avignon. King John, and after him Charles V. collected the first volumes of the Royal Library; and Froissart, who by his simple and artless history does so much honour to the literature of France, commenced, under the latter prince, that series of French poets which has never since been interrupted. The praises of Laura diffused amongst the women a taste for Italian poetry; and one lady, whose name still survives in literary history, Justina de Levis, addressed a sonnet to Petrarch, which elicited from his gallantry or judgment warm commendation. Chaucer, who was preparing to found a literature in England, saw him in Italy, and was perhaps indebted to him for the acquaintance of Boccacio, whom he has so frequently imitated in his works. Another Englishman, Richard de Bury, one of the correspondents of Petrarch, founded a library at Oxford, and diffused throughout his country a taste for books. As yet Spain had only her early historical romances, and some theologians; but two centuries later, the poetical admirer of Laura found in Boscan an imitator at the court of Castille, whilst Bembo, Tarsia, Molsa, and many others, opened in Italy the dangerous school of the Petrarchists.

The Letters of Petrarch, which were printed for the first time in 1484, though without the name of the place, are now regarded as the most curious portion of his Latin works. These letters, which were not written exclusively for his friends, contain valuable details in regard to his life, as well as the manners and the history, literary and political, of the fourteenth century. The court of Avignon is by no means spared; and the author was too good an Italian not in some instances to overcharge a little his portraits. His expression is animated, but not always natural, and his prose often betrays the poet. His books of moral philosophy somewhat resemble those common-places which were treated by the Greek rhetoricians of the middle age. That which he has entitled Remedies against both kinds of Fortune has for its object to show, that earthly goods are perishable, and that there exists no evil without a remedy.[1] The treatise *De Otio Religiosorum* was a tribute of complaisance to the Carthusian friars of Montrieu, amongst whom his brother had taken the habit of the order;[2] and it was at the urgent entreaty of Francesco de Carrara that he collected the principal maxims of Plato and Cicero on politics, under the title of *De Republica optime administranda*, which might have suited a more methodical and extended composition. The compilation in question, and his treatise *De Officio et Virtutibus Imperatoris*, were printed separately at Berne, 1602, in 12mo; and though these little works have since been effaced by so many other superior productions, yet they are the offspring of a judicious mind, which neither flattered authority on the one hand, nor disregarded the rights of mankind on the other. In his retreat at Arqua, he also wrote a truly philosophical work against the disciples of Aristotle, under this piquant denomination, *De Ignorantia sui ipsius et multorum*. His Historical Essays, of which some fragments have been preserved, entitled *Rerum Memorandarum libri iv.*, in addition to the facts which he has borrowed from preceding writers, contain some particulars belonging to contemporaneous history, which are nowhere else to be found. The perusal of the Confessions of St Augustin appears to have suggested to him the most singular of all his compositions, namely, the three dialogues, *De Contemptu Mundi*, to which he attached so much importance as to call them "his secret." The author communes with St Augustin on his own character, tastes, and weaknesses; he confesses his faults with the simplicity of childhood, and, on the other hand, St Augustin lectures him with an authority tempered by mildness, and a dignity softened by sympathizing benevolence.

The harangues of Petrarch are not always exempt from declamation, and, more than any of his other productions, betray the influence of the false taste against which he so successfully strove. But his Latin poetry has particular claims to the attention of men of letters. His poem of *Africa* has been compared to those pictures and statues, the productions of the infancy of art, which, without augmenting its glory, may be examined with advantage by those who desire to study its progress. It is a detailed recital of the second Punic war, but almost always cold and colourless. It is a chronicle rather than a poem, and appears as if it had been left unfinished. The *mens divinior* is wanting; invention there is none; and we are astonished to find that the poetry of Virgil produced so little inspiration. His eclogues, like those of Boccacio, are almost always satirical allegories, having reference to contemporaneous events. The tenth is consecrated to the memory of Laura. In his three books of Epistles, versified with more facility than might have been expected in that iron age, there are some interesting and instructive details. In fact, the Latin diction of Petrarch, though generally superior to the bald and rude style of his contemporaries, is nevertheless far below that of his models. His composition is vigorous without being harsh, and on some occasions he is deficient neither in elegance nor in energy; but he more frequently reminds us of St Augustin than of Cicero, whom he professed not only to admire, but to imitate. Still, it was on his Latin works that Petrarch founded his claims to distinction as an author; and, what is not a little remarkable, this was also the error of Boccacio. These misjudgments of genius, of which we have examples both in Homer and in Milton, as well as in the two illustrious men we have just named, would form a curious subject of literary speculation, were this the place in which it could with propriety be discussed.

But Petrarch's best title to distinction rests upon his *Canzoniere*. It is there that he shows himself truly inspired, and displays in profusion all the riches of his original genius. The ancient erotic poets, strangers to any ennobling sentiment, had celebrated pleasure rather than love. That respect for women which had so long existed amongst the nations of the North; that worship of beauty, ennobled by the still recent recollections of chivalry; those feats of valour which were days of triumph to the ladies; all this was wanting to pagan society. Petrarch, therefore, stands alone, because his passion resembled nothing which the ancients had known. The early songs of the troubadours had embodied the natural expression of the manners of chivalry. The examples which they had presented, the traditions which they had left, as well as the unfortunate refinements of the Italians, their imitators, and the idle subtleties of the courts of love, a sad parody of the forms, and often of the obscurities, of the schools, had created amongst the moderns a language to which rhyme added its shackles; a language which was no longer the vulgar language, but yet was not that of poetry. To this the lover of Laura imparted all that the superiority of his genius had taught him. We have seen that he had studied Plato. But although his mind had, unaided, divined the disciple of Socrates, yet that union of souls which the philosopher had sometimes dreamed of was as remote from the sentiment which inspired Petrarch as the domestic manners of the Greeks differed from those of the fourteenth century. It was not Platonic love which had animated the poet; it was love such as Christianity and chivalry had made it. This love, which the corruption of our age has pronounced supernatural, is poetical in a very different sense from that which inspired Propertius and Ovid. It no doubt wants movement and variety; but it has a true and penetrating warmth, an elevation which rises to the sublime, and a purity which has in it something almost celestial. Petrarch was the first, and for a long time the only poet, who made a virtue of love. The Italian, created by Dante, had even after his time retained somewhat of that harshness which is still apt to shock the reader in some parts of his *Inferno*. Petrarch formed for himself a language, as Dante had done; his turns of expression are almost as bold; above all, he reproduced those graces of colouring and that delicious harmony with which Dante had related the misfortunes of his Francesca; and, after the publication of the *Canzoniere*, the Italian idiom ceased to have in it any thing barbarous. When we read the verses of Petrarch, we can almost fancy that we hear the sound of his lyre, from which, on every occasion, he extracts sounds of an ineffable sweetness. In the first part, where he celebrates the perfections of Laura, his expression becomes dreamy or ecstatic; in the second, where he laments his mistress, his song has a solemn and penetrating accent. Sometimes he lends his lute to chant the lessons of philosophy; at other times it is the Hebrew harp resounding the maledictions of the prophets, or a Roman muse bewailing the debasement and misfortunes of her country. Those who love comparisons and coincidences have remarked, that the sonnets, from their form, remind us of some of the smaller odes of Horace, and, for grace as well as simplicity of details, recall the manner of the poet of Teos. For this kind of poetry Petrarch was indebted to his predecessors; but it was he who rendered these little poems more perfect and more difficult; and the laws which his example prescribed have not yet been abrogated.

---

[1] In the *Archives Littéraires* (tom. ii. pp. 259-286), M. de Gerando has translated some fragments of this very common-place dialogue under the title of the Philosophy of Petrarch (*De la Philosophie de Pétrarque*).

[2] Several biographers have given Petrarch a sister, who, they say, was beloved by Pope Benedict XII. This fable, which has been received without question by Protestants, and thoughtlessly repeated by Villaret, and even by Henry, is disproved by the fact, which Ginguené has clearly established, namely, that Petrarch never had a sister.

The *Canzoni* of Petrarch, which have been improperly rendered *Chansons* by Voltaire, are odes the form of which he borrowed from the troubadours, whilst to the substance he imparted the elevation and dignity of epic composition. The Italians have exhausted all the prescriptive terms of admiration upon those which Petrarch appears to have preferred, and which he called the Three Sisters, odes which his commentators have since named the Three Graces. The eyes of Laura form the subject of these three odes, which are the eighteenth, nineteenth, and twentieth of the collection. But whatever may be the perfection of style for which they are distinguished, a reader of the present day will always find difficulty in comprehending the long literary superstition of which they have been the object. Graver readers will no doubt prefer the *Canzone* on the crusade, which is the fifth in the collection, and that magnificent ode, so truly national, in which the poet retraces, *en traits de feu*, the oppression of his beloved Italy, and shows her bleeding and mutilated, yet still full of glory, and capable of recovering from her wounds; compositions so little known to those superficial *littérateurs* who have mistaken a man of the greatest genius, who formed a language and created a literature, for a mere grinder of madrigals. All those who know the language of Petrarch have cited, amongst the monuments of his love, the celebrated sonnets,

> Solo e pensoso i più deserti campi
> Vo misurando a passi tardi e lenti;
> E gli occhi porto, per fuggire, intenti
> Dove vestigio uman la rena stampi,

being the twenty-eighth of the first part; and

> Levommi il mio pensier in parte ov'era
> Quella ch' io cerco e non ritrovo in terra:
> Ivi fra lor che 'l terzo cerchio serra,
> La rividi più bella, e meno altera,

which is the thirty-fourth of the second part; besides many other *Canzoni* not less admired, amongst which it would be difficult to make a selection. We shall only refer our readers to the twenty-seventh, the first strophe of which has been so happily imitated by Voltaire. The latter, however, has not been equally fortunate in his judgment of Petrarch; and Sismondi, without indulging in the same levity, has shown himself almost equally severe. But the monotony with which Petrarch has been reproached is perhaps rather a defect inherent in the particular species than one peculiar to the poet. The lover of Laura bewails himself, since complain he must, and this eternal lamentation is without doubt sometimes fatiguing; but love rejoices in such repetitions; and Petrarch has varied as much as possible this uniformity, by pictures of rustic life full of natural grace and simplicity, or by high and ennobling religious contemplations. We do not say, however, that his poems, and especially his sonnets, have escaped all tincture of the prevailing taste of his age. On the contrary, he is often more ingenious than natural, and more elaborate than correct; but a re-perusal of the second half of the *Canzoniere*, which is very generally preferred to the first, must satisfy any reader that nothing short of extreme injustice or inveterate prejudice can construe into a mere play of words or sport of ingenuity a grief which is stamped with all the characteristics of truth, deep feeling, and sincerity.

The most complete edition of the works of Petrarch is that of Basel, 1581, in folio, which wants only a certain number of Letters, comprised in that of Geneva, 1601. The most ancient edition of his Latin works also bears the name of Basel, where it appeared in 1496, in folio. But it is in the libraries of Italy that his Letters and his Autograph Manuscripts must be sought for. The treatise De Remediis utriusque Fortunæ was printed at Cologne, 1471, in 4to, and has been thrice translated into French; and the historical work entitled Vite de' Pontefici et Imperadori Romani, which has now become exceedingly scarce, appeared at Florence, 1478, in folio, and is still much sought after, as one of the most ancient monuments of Italian prose. In later times, his Italian poems alone have been reprinted. The first edition, containing the Sonetti and the Trionfi, is that of Venice, 1470, in large 4to. Amongst the subsequent editions, the most esteemed are, 1. Le Cose Volgari, by Aldus Manutius, Venice, 1501, in 8vo; 2. Il Petrarca, Lyons, 1574, in 16to; 3. Le Rime di Petrarca, Padua, 1722, in 8vo; 4. A reprint of the same, with notes by Muratori, Venice, 1727, in 4to; 5. The editions of Bodoni, 1799, in two vols. folio and 8vo; 6. That of Morelli, the librarian, with Remarks by Beccadelli, Verona, 1799, in two small vols. 8vo; 7. That which forms part of the Biblioteca Poetica Italiana, published by Buttura, and printed by Didot the elder, Paris, in three small vols.; and, 8. The edition, with Commentaries, published by Biagioli in 1822, in 8vo. Petrarch is said to have been the subject of twenty-five distinct biographies, exclusive of the sketches of his life given in collections. Of these lives, the most copious, though by no means the most accurate, is that of the Abbé de Sade; and as to Lord Woodhouselee's Historical and Critical Essay on the Life and Character of Petrarch, published in 1810, Lord Byron has dryly remarked, "Thanks to the critical acumen of a Scotchman, we know as little of Laura as ever." (A.)

PETREL ISLAND, a small island in Dusky Bay, near the coast of New Zealand, a little to the north of the harbour in Anchor Island. It is also the name of a bay on the south coast of New Holland. Long. 133. 15. 30. E. Lat. 32. 33. 30. S.

PETRIFACTION, in *Natural History*, denotes the conversion of wood, bones, and some other substances, whether animal or vegetable, into stone. These bodies are more or less altered from their original state, according to the different substances amongst which they have lain buried in the earth; some of them having suffered very little change, and others being so highly impregnated with crystalline, sparry, pyritical, or other extraneous matter, as to appear mere masses of stone or lumps of the matter of the common pyrites. But they are generally of the same external dimensions, and retain more or less of the same internal figure, as the bodies into the pores of which this matter has made its way. The animal substances thus found petrified are chiefly sea-shells, the teeth, bony palates, and bones of fishes, the bones of land-animals, and some others. These are found variously altered, by the insinuation of stony and mineral matter into their pores; and the substance of some of them is found to be wholly gone, leaving only stony, sparry, or other mineral matter remaining in the original shape and form.

Respecting the manner in which petrifaction is accomplished, we know but little. It has been thought by many philosophers, that this is one of the occult processes of nature; and accordingly such places as afford a view of it have been looked upon as great curiosities. However, it is now discovered that petrifaction is exceedingly common, and that every kind of water carries in it some earthy particles, which being precipitated, become stone of a greater or less degree of hardness; and this quality is most remarkable in those waters which are much impregnated with selenitic matter. It has been found by observation, that iron contributes greatly to the process; and this it may do by its precipitation of any aluminous earth which happens to be dissolved in the water by means of an acid, iron having the property of precipitating this earth. Calcareous earth, however, by being soluble in water without any acid, must contribute greatly to the process of petrifaction, as its particles are capable of acquiring a great degree of hardness by means only of being joined with fixed air, on which depends the solidity of our common cement or mortar used in building houses.

The name of petrifaction, as we have seen, belongs only to bodies of vegetable or animal origin; and in order to determine their class and genus, or even species, it is necessary that their texture, their primitive form, and in some measure also their organization, should be still discernible. Thus, we ought not to place the stony kernels, moulded in the cavity of some shell, or other organized body, in the rank of petrifactions properly so called.

Petrifactions of the vegetable kingdom are almost all either gravelly or siliceous; and they are found in gullies, trenches, and other situations. Those which strike fire with steel are principally found in sandy fissures; those which effervesce in acids are generally of animal origin, and are found in the horizontal beds of calcareous earth, and sometimes in beds of clay or gravel, in which last case the nature of the petrifaction is different. As to the substances which are found in gypsum, they seldom undergo any alteration, either with respect to figure or composition, and they are of very rare occurrence.

Organized bodies, in a state of petrifaction, generally acquire a degree of solidity of which they were not possessed when they were buried in the earth, and some of them are often fully as hard as the stones or matrices in which they are enveloped. When the stones are broken, the fragments of petrifactions are readily found, and easily distinguished. There are some organized bodies, however, so changed by petrifaction, as to render it impossible to discover their origin. That there is a matter more or less agitated, and adapted for penetrating bodies, which crumbles and separates their parts, and disperses them here and there in the fluid which surrounds them, is a fact of which nobody seems to entertain any doubt. Indeed we see almost every substance, whether solid or liquid, insensibly consume, diminish in bulk, and at last, in the lapse of time, vanish and disappear.

A petrified substance, strictly speaking, is nothing more than the skeleton, or perhaps the form, of a body which has once had life, either animal or vegetable, combined with some mineral. Thus, petrified wood is not, in that state, wood alone. One part of the compound or mass of wood, having been destroyed by local causes, has been compensated by earthy and sandy substances, diluted and extremely minute, which the waters surrounding them had deposited, whilst they themselves evaporated. These earthy substances, being then moulded in the skeleton, will be more or less indurated, and will appear to have its figure, structure, and size, in a word, the same general characters, the same specific attributes, and the same individual differences. Further, in petrified wood, no trace or vestige of ligneous matter appears to exist. We know that common wood is a body in which the volume of solid parts is greatly exceeded by that of the pores. When wood is buried in certain places, lapidific fluids, extremely divided and sometimes coloured, insinuate themselves into its pores and fill them up. These fluids are afterwards moulded and condensed. The solid part of the wood is decomposed and reduced into powder, which is expelled from the mass by aqueous filtrations; and thus the places which were formerly occupied by the wood are now left empty in the form of pores. This operation of nature produces no apparent difference either of the size or of the shape; but it occasions, both at the surface and in the interior, a change of substance, and the ligneous texture is inverted, or, in other words, that which was pore in the natural wood becomes solid in the petrified, and that which was solid or full in the first state becomes porous in the second. In this way, says Musard, petrified wood is much less extended in pores than solid parts, and at the same time forms a body much denser and heavier than the first. As the pores communicate from the circumference to the centre, the petrifaction ought to begin at the centre, and end with the circumference of the organic body subjected to the action of the lapidific fluids. Such is the origin of petrifactions. They are organized bodies which have undergone changes at the bottom of the sea or the surface of the earth, and which have been buried by various accidents at different depths under the ground. See Mineralogy and Geology.

PETROBRUSSIANS, a religious sect, which took its rise in France and the Netherlands about the year 1110. The name is derived from *Peter Bruys*, a Provençal, who made a most laudable attempt to reform the abuses and remove the superstition which disgraced the beautiful simplicity of the gospel. His followers were numerous, and for twenty years his labour in the ministry was exemplary and unremitted. He was, however, burned in the year 1130, by an enraged populace, said to have been set on by the clergy.

The most noted of Bruys's followers was a monk named Henry, from whom the Petrobrussians were also called *Henricians*. Peter the Venerable, abbot of Clugny, wrote a treatise expressly against the Petrobrussians, in the preface to which he reduces their opinions to five heads. They denied that children before the age of reason can be justified by baptism, as it is our own faith that saves by baptism. They held that no churches should be built, an inn being as proper for prayers as a temple, and a stable as an altar; that the cross ought to be pulled down and burned, because we ought to abhor the instrument of our Saviour's passion; that the real body and blood of Christ are not exhibited in the eucharist, but merely represented by figures and symbols; and that sacrifices, alms, prayers, and the like, do not avail the dead. Langlois accuses the Petrobrussians of Manicheism, and says, they maintained two gods, the one good, the other evil; but this is rather an effect of his zeal for the Catholic cause, which led him to blacken its adversaries, than any real sentiment of the Petrobrussians.

PETROJOANNITES were followers of Peter John, or Peter Joannis, that is, Peter the son of John, who flourished in the twelfth century. His doctrine was not known until after his death, when his body was taken out of his grave and burned. His opinions were, that he alone had the knowledge of the true sense in which the apostles preached the gospel; that the reasonable soul is not the form of man; that there is no grace infused by baptism; and that Jesus Christ was pierced with a lance on the cross before he expired.

PETROLEUM, or Rock Oil, a thick oily substance exuding from the earth, and collected on the surface of wells, in many parts of the world.

PETRONIUS Arbiter, C. the author of a kind of romance, the earliest with which we are acquainted, was born at Massilia, and is supposed to be the same of whom some account is given by Tacitus (*Ann.* xvi. 18). As proconsul, he administered the province of Bithynia with considerable ability, and on his return to Rome he became the favourite of Nero, and the director as well as participator of all his pleasures. His influence with the emperor excited the envy and jealousy of Tigellinus, and that minister soon found an opportunity of putting an end to his connection with Nero. Petronius chose his own mode of closing his life, A. D. 67, that he might escape a severer punishment. There is no certainty, however, that this individual, of whom Tacitus gives an account, is the same with the author of the work of which fragments have come down to us; but even if he be not, still there is no doubt that he must have flourished about this period, from the classical purity of his language, and the general arrangement of his subject. The work is entitled *Satyricon;* and of it we have only some fragments, which seem to have formed part of a selection from his work. It contains the adventures of a certain freedman, Encolpius, sometimes of a tragical, sometimes of a comical nature, which gives an opportunity to the author of narrating fully the follies and vices of his age. There has been preserved a beautiful episode, the Matron of Ephesus and the Supper of Trimalchio, which admits us to the domestic circles of the noble Romans, and makes us acquainted with their voluptuous mode of life. The characters are well drawn; the whole idea of the scene is got up with much spirit as well as art; and there are some beautiful descriptions, which make us regret that he should have wasted his talents on common and obscene subjects. The obscenity of much that is preserved is of the most gross and licentious nature; but the beauty of his style, and the purity of his expressions, remind us of the classical period of Roman literature. The best edition is that of Burmann (Traj. ad Rhen. 1709).

PETROPAULOSKAIA, a fortress of Asiatic Russia, in the government of Irkoutsk, sixteen miles south-south-west of Selenginsk. Another fortress in the government of Oufa, 52 miles east-north-east of Verchouralsk. Also a town of Asiatic Russia, in the government of Tobolsk, on the Ischim, forty miles east of Ischim.

PETROSOWODSK, a city of Russia, in the government of Olonez, and the capital of a circle of its own name. It is situated on a bay of the Lake of Onega, and by means of the Salma is connected with the Lake of Lagmosero. It is poorly built, but contains 390 houses, mostly of wood, and 3280 inhabitants, who trade in pitch, tar, and ship-timber; and near it there are some large iron-works. It is 303 miles from St Petersburg. Long. 34. 18. 25. E. Lat. 61. 47. 4. N.

PETSCHANOI, a fortress of Asiatic Russia, in the government of Kolivan, 188 miles west-south-west of Kolivan. Also a cape on the northern coast of Asiatic Russia, in the Frozen Sea. Long. 165. 14. E. Lat. 75. 25. N.

PETTEIA, in the ancient music, a term to which we have no one corresponding in our language. The melopœia, or the art of arranging sounds in succession so as to produce melody, is divided into three parts, which the Greeks call *lepsis*, *mixis*, and *chresis;* the Latins, *sumptio*, *mixio*, and *usus;* and the Italians, *presa*, *mescolamento*, and *uso*. The last of these is called by the Greeks πεττεια, and by the Italians *pettia;* which therefore means the art of making a just discernment of all the manners of ranging or combining sounds amongst themselves, so that they may produce their effect, or express the several passions intended to be raised. Thus it shows what sounds are to be used, and what not; how often they are severally to be repeated; with which to begin and with which to end; whether with a grave sound to rise, or an acute one to fall, &c. The petteia constitutes the manners of the music; chooses out this or that passion, this or that motion of the soul, to be awakened; and determines whether it be proper to excite it on this or on that occasion. The petteia, therefore, is in music much what the manners are in poetry.

It is not easy to discover whence the denomination should have been taken by the Greeks, unless from πεττεια, their game of chess, the musical petteia being a sort of combination and arrangement of sounds, as chess is of pieces called πεττιο, *calculi*, or chess-men.

PETTIPORE, or PETTAPORE, a town of Hindustan, in the Northern Circars, and district of Rajamundry, thirty-three miles east-north-east from the town of Rajamundry. Long. 82. 25. E. Lat. 27. 5. N.

Petty.

PETTY, SIR WILLIAM, a man eminently distinguished for his learning, mechanical ingenuity, and political writings, was the eldest son of Antony Petty, a clothier at Rumsey, in Hampshire, where he was born on the 16th of May 1623. Petty, when a boy, was noted for the pleasure he took in observing mechanics at work, and the facility with which he comprehended the nature of their employments and the use of their tools. He received the rudiments of his education at the grammar-school of Rumsey, where, before the age of fifteen, he had acquired a competent knowledge of the Latin, Greek, and French languages, and made himself master of the common rules of arithmetic, as well as of the elements of geometry, dialling, and navigation. He then removed to the University of Caen, in Normandy, taking with him a small stock of merchandise, which he disposed of to so much advantage, that he maintained himself out of the profits of his traffic, and at the same time perfected himself in Latin and French, acquired enough of Greek "to serve his turn," studied the arts, and extended his knowledge of the mathematics. Even at this early period the prevailing bias of his mind displayed itself; and in the student of Caen we discover the father of the man who, holding that there are few ways in which a person may be more harmlessly employed than in getting money, afterwards realized a very great fortune. On his return from France, he was appointed to the navy, though in what capacity is not known. In this situation he remained for some time, and having saved about L.60, he determined to bid adieu to the navy, and travel for further improvement. Having made choice of physic as a profession, he, in 1643, visited Leyden, Utrecht, and Paris, where he studied anatomy, and read Vesalius with Hobbes, whom he in turn assisted by drawing diagrams for the philosopher, who was then writing on optics. Whilst at Paris he appears to have been reduced to great straits from want of money; but his ingenuity and industry extricated him from all his difficulties; and, in 1646, he returned home a richer man than when he had set out, although he had maintained his brother Antony as well as himself.

Petty was not a man to remain inactive or slothful. It appears indeed that, on the 6th of March 1647, a patent was granted him by parliament for an invention which would now be termed a copying-machine, but which he calls an instrument for double writing. In an advertisement prefixed to his Advice to Mr Samuel Hartlib, he describes it as an instrument of small bulk and price, easily made, and very durable, by means of which "any man, even at the first sight and handling, may write two resembling copies of the same thing at once, as serviceably and as fast as by the ordinary way;" and Rushworth informs us that it might be learned in an hour's practice, and was calculated to be of great advantage to lawyers, scriveners, merchants, scholars, registrars, clerks, and others, by saving the labour of examination, and discovering or preventing falsification. But this machine having been found not to promote expedition in writing, the principal advantage proposed to be attained by it, Petty did not reap much profit by his invention; but, although it failed of its object in this respect, it served to make him acquainted with the leading men of the times. His next production was a pamphlet entitled Advice to Mr Hartlib for the Advancement of Learning, containing some sensible remarks on national education, particularly in as far as regards the more useful branches of knowledge, which he justly conceived were too much neglected. In 1648 he went to Oxford, where he gave instructions in anatomy as a private teacher; became assistant to Dr Clayton, the professor of anatomy, who had an insurmountable aversion to the sight of a

Petty.

mangled corpse; and also practised physic with considerable success. Here he acquired such reputation, that the philosophical meetings which led to the institution of the Royal Society were for the most part held at his lodgings; and, by a parliamentary recommendation, he obtained a fellowship in Brazen-nose College, and was created doctor of physic on the 7th of March 1649. In June 1650, he was admitted a member of the College of Physicians; and the same year he was concerned in the recovery of a woman, named Anne Green, who had been hanged at Oxford for the supposed murder of her bastard child. In the beginning of 1651, he was appointed professor of anatomy, and soon afterwards professor of music, at Gresham College; and in 1652, he went to Ireland as physician to the army in that country, where he served under three successive lords-lieutenant, namely, Lambert, Fleetwood, and Henry Cromwell.

Some time after his settlement in Ireland, Dr Petty observing that the forfeited lands adjudged to the soldiers, after the suppression of the rebellion of 1641, were very inaccurately measured, represented the matter to the persons then in power; and a contract, dated the 11th of December 1654, was in consequence granted him, by which he was authorized to make the admeasurements anew, a duty which he appears to have discharged with exactness and fidelity. By this contract he gained a very considerable sum of money; for, besides the twenty shillings a day which he received during its performance, he had also, by agreement with the soldiers, a penny an acre for the lands measured by him; and by an order of government, dated the 19th of March 1655, it appears that he had then surveyed 2,008,000 acres, which, at the rate stipulated, must have yielded him about L.8400 sterling. He was likewise one of the commissioners for allocating the lands to the soldiers after they had been surveyed. In 1655, Henry Cromwell assumed the lord-lieutenancy of Ireland, and soon afterwards appointed Dr Petty his secretary; in 1657, the viceroy further appointed him clerk of the council, and got him elected to serve as burgess for West Love, in Cornwall, in Richard Cromwell's parliament, which assembled on the 27th of January 1658. But this last honour speedily involved him in trouble. On the 28th of March following he was impeached of high crimes and misdemeanours in the execution of his office, and obliged to proceed to England. On the 19th of April he appeared in the House of Commons, and answered to the charge on the 21st; the prosecutors then replied, after which the matter was adjourned, and never came to an issue, as the parliament was suddenly dissolved the next day. He soon afterwards returned to Ireland, where, some further attempts being made to bring on a prosecution, he published two pamphlets; the one giving an account of the proceedings in the impeachment, and the other containing reflections on some persons and things in Ireland. Finding the latter country getting too hot for him, he crossed over to England, provided with a warm application in his favour by the lord-lieutenant; but, notwithstanding this intercession, he was in June removed from all his employments.

The charges brought against him were six in number. He was accused of having received or taken great bribes; of having made a trade of buying debentures, contrary to the statute; of having obtained by fraud large sums of money and extensive tracts of land; of having employed many foul practices, as surveying and setting out lands; of having, along with his fellow-commissioners, placed some debentures in better situations than they could claim, and denied right to others; and, lastly, he and his fellow-commissioners were accused of having totally disposed of the army's security for payment, whilst the debt still remained chargeable on the state. Petty's answer to these charges is abundantly curious. Instead of trying to refute them in detail, he labours to show that, without ever intermeddling with the surveys of the Irish lands, he *might* have acquired as large a fortune by other means; and, certainly, whatever may be thought of such a defence to specific charges of malversation and fraud, the statement itself must be allowed the praise of ingenuity.

In 1659, the republican spirit not being yet extinct in Petty, he became a member of the Rota Club, which met at Miles's coffee-house, in New Palace-yard, Westminster. This club received its name from the strange practice it was intended to support, namely, that all officers of state should be chosen by ballot, that the time for holding their places should be limited, and that a certain number of members of parliament should be annually changed by rotation. But the star of the commonwealth was now waxing dim, and, not long after Christmas, Petty went to Ireland. At the Restoration, however, he came back to England, where he was graciously received by Charles II., and, having resigned his professorship at Gresham College, was appointed one of the commissioners of the Court of Claims. In April 1661, he received the honour of knighthood, with the grant of a new patent constituting him surveyor-general of Ireland; and he was at the same time chosen a member of the Irish parliament. Being one of the founders of the Royal Society, he was elected a member of the first council; and although he had left off the practice of physic, his name appears in the list of fellows of the College of Physicians in 1663. About this time he invented a double-bottomed ship, which was to sail against both wind and tide, though we are not told by what means; and, in 1665, he communicated to the Royal Society, along with a model of his invention, a Discourse about the Building of Ships, which being supposed to contain matter too important to be divulged, was taken away by the president, Lord Brounker, who kept it in his possession till 1682, and probably till his death, which happened not long afterwards.

In 1666, Sir William Petty drew up his treatise entitled *Verbum Sapienti*, containing an account of the wealth and expenditure of England, showing the method of raising taxes in the most equal manner, and endeavouring to prove, that England could bear a charge of four millions per annum, when the exigencies of the government required it. The same year he suffered a considerable loss by the fire of London, the greater part of his house and gardens having been destroyed by that terrible conflagration. In 1667, he married Elizabeth, daughter of Sir Hardresse Waller, and widow of Sir Maurice Fenton. This matrimonial connection, however, did not for a moment distract his attention from his favourite pursuit of making money; for immediately afterwards he established iron-works and a pilchard-fishery, opened lead mines, and commenced a trade in timber at Kerry, all of which turned to good account. To vary his pursuits, he also composed a piece of Latin poetry, which he subsequently published under the title of *Colloquium Davidis cum Anima sua*. In 1680, he gave to the world his Politician Discovered, intended to expose the sinister practices of the French; and afterwards wrote several essays on Political Arithmetic, in which, from considering the natural resources of England and Ireland, he shows how both may be strengthened, improved, and rendered superior to all their rivals or enemies. He assisted at the formation of the Dublin Philosophical Society, and in November 1684 was chosen president of that association. On this occasion he drew up a Catalogue of Cheap and Simple Experiments, which was soon afterwards followed by his *Suppellex Philosophica*, containing a description of forty instruments which he deemed necessary to carry forward the design of the institution. But the ultimate term of all his projects and pursuits was now approaching. A gangrene in his foot, occasioned by the swelling of the gout, having resisted every mode of treatment, at length put a period to his life, on the 16th of December 1687, in the sixty-fifth year of his age. He died at his house in Piccadilly, and his remains were interred at Rumsey, near those of his parents. His will is perhaps the most curious and characteristic composition of the kind in our language, illustrating at once the habits of thinking and feeling peculiar to the man, and the mode in which he realized the enormous fortune which he left to his descendants.[1]

A few particulars of the personal history of Sir William Petty may be gleaned from Aubrey, who appears to have lived with him on terms of intimacy. He possessed strong, shrewd, natural good sense, flavoured with a tincture of humour, and had a most convenient way of shaking himself rid of the trammels of party when it suited his interest to do so, changing sides with a facility that is altogether edifying. His qualifications were indeed various and peculiar. He was an excellent droll, as he showed by proposing to Sir Jerome Sankey, who had challenged him, to fight in a dark cellar with carpenters' axes; a proposal in which the knight, though he had been a soldier, did not deem it prudent to acquiesce. He would also preach extempore, which Aubrey says he did "incomparably," and that too in almost any style, "either in the presbyterian way, independent, capucin friar, or Jesuit." He had "an admirable inventive head, and practical parts," which he turned to good account as far as his own interest was concerned; and, like his friend Hobbes, he boasted that he had read but little since he was twenty-five, declaring, that "had he read as much as some men have, he had not known so much as he does, nor should have made such discoveries and improvements." He told Aubrey that he had "hewed out his fortune for himself," and he even managed to obtain a patent of nobility as Earl of Kilmore, which, however, he suppressed to avoid envy. The variety of pursuits in which he was engaged shows that he had talents capable of achieving any thing to which he chose to apply them; and it is certainly not a little remarkable, that a man of such an active and enterprising disposition should have found time to write so much as he did in the course of his busy life.

The following is a list of the works which appeared in his lifetime: 1. Advice to Mr Samuel Hartlib, 1648, in 4to; 2. A Brief of Proceedings between Sir Jerome Sankey and the Author, 1659, in folio; 3. Reflections on some Persons and Things in Ireland, 1660, in 8vo; 4. A Treatise of Taxes and Contributions, 1662, in 4to, republished in 1690, with two other pieces; 5. Apparatus to the History of the Common Practice of Dyeing, 1667; 6. A Discourse concerning Duplicate Proportion, 1674, in 12mo; 7. Colloquium Davidis cum Anima sua, 1679, in folio; 8. The Politician Discovered, 1681, in 4to; 9. An Essay on Political Arithmetic, 1682, in 8vo; 10. Observations upon the Dublin Bills of Mortality in 1681, 1683, in 8vo; 11. Some Experiments relating to Land-carriage, Phil. Trans. No. 161; 12. Queries on Mineral Waters, ibid. No. 166; 13. A Catalogue of Experiments, ibid. No. 167; 14. Maps of Ireland, being an actual Survey of the whole Kingdom, 1685, in folio; 15. An Essay concerning the Multiplication of Mankind, 1686, in 8vo; 16. A further Assertion concerning the Magnitude of London, Phil. Trans. No. 185; 17. Two Essays in Political Arithmetic, 1687, in 8vo; 18. Five Essays in Political Arithmetic, English and French, 1687, in 8vo; 19. Observations upon London and Rome, 1687, in 8vo.

His posthumous productions are, 1. Political Arithmetic, 1690, in 8vo, and 1755, with a Life prefixed, and a Letter never before printed; 2. The Political Anatomy of Ireland, to which is added, Verbum Sapienti, 1691, 1719; 3. A Treatise of Naval Philosophy, in three parts, printed at the end of an Account of Several New Inventions, 1691, in 12mo; 4. What a Complete Treatise of Navigation should contain, Phil. Trans. No. 198, drawn up in 1685. In Birch's History of the Royal Society are contained, 1. A Discourse of making Cloth and Sheep's Wool, containing the History of the Clothing Trade, and also that of Dyeing; and, 2. *Suppellex Philosophica*, already mentioned. There are many of Sir William Petty's manuscripts in the British Museum, amongst which is a sort of confession of his faith, corresponding with the concluding passage of his will, in which he says, "I die in the profession of that faith, and in the practice of such worship, as I find established by the law of my country," a very honest and candid declaration on his part. (A.)

PETTYCOTTA, a town of Hindustan, in the Southern Carnatic, and the province of Tanjore, thirty-two miles south by east from the town of Tanjore. Long. 79. 22. E. Lat. 16. 21. N.

PETWORTH, a market-town of the county of Sussex, in the rape of Arundel, and hundred of Rotherbridge. It is situated on the river Arun, fifty miles from London, and has a market which is held on Saturday. The streets are irregular, but the whole appearance is clean. The church is a fine object, and has a very lofty spire. The chief object of attraction is the magnificent mansion and park of the Earl of Egremont, the descendant of the celebrated Sir William Wyndham, to whom it, with other large estates, descended from the Percys, Earls of Northumberland, by a female branch. The population in 1801 amounted to 2264, in 1811 to 2459, in 1821 to 2781, and in 1831 to 3114.

PEWSEY, a town of the county of Wilts, in the hundred of Kinwardstone, seventy-six miles from London. The population in 1801 amounted to 1179, in 1811 to 1209, in 1821 to 1337, and in 1831 to 1588.

PEWSUM, a town of the kingdom of Hanover, in the province of East Friesland, the capital of a bailiwick of the same name, which extends over fifty-four square miles, and contains, besides the town, fourteen parishes, with 6320 inhabitants.

PEWTER, a factitious metal, used in the making of domestic utensils. The basis of this metal is tin, united to small portions of lead, zinc, bismuth, and antimony. There are three sorts of pewter in common use, distinguished by the names of *plate*, *trifle*, and *ley*. The plate-pewter is used for plates and dishes; the trifle, chiefly for pints and quarts;

---

[1] As a specimen of this extraordinary composition, we shall take leave to introduce here the following extract, which appears to us to be eminently characteristic: "As for legacies for the poor, I am at a stand; as for beggars by trade and election, I give them nothing; as for impotents by the hand of God, the public ought to maintain them; as for those who have been bred to no calling or estate, they should be put upon their kindred; as for those who can get no work, the magistrate should cause them to be employed, which may be well done in Ireland, where is (are) fifteen acres of improvable land for every head; prisoners for crime, by the king; for debts, by their prosecutors; as for those who compassionate the sufferings of any object, let them relieve them, and relieve themselves by relieving such sufferings, that is, give them alms *pro re nata*, and for God's sake relieve those several species above mentioned, where the above-mentioned obligers fail in their duties: Wherefore I am contented that I have assisted all my poor relations, and put many in a way of getting their own bread, and have laboured in public works, and by inventions have sought out real objects of charity; and do hereby conjure all who partake of my estate, from time to time to do the same at their peril. Nevertheless, *to answer custom, and to take the surer side*, I give L.20 to the most wanting of the parish wherein I die." Here we have the domain of charity laid out by a political economist; and after the exclusion of the various classes above specified, it must be confessed that enough will scarcely remain to render it discernible on the map of the moral duties; though, "to answer custom and to take the surer side," a prudent Dives may, out of his enormous wealth, leave some L.20 to the most destitute of the parish wherein death separates him from all his earthly possessions.

and the ley-metal for wine measures, and the like. Our very best pewter is said to consist of a hundred parts of tin and seventeen of antimony, though others allow only ten parts of the latter metal. Besides this composition, there are other kinds, compounded of tin, antimony, bismuth, and copper, in several proportions.

PEYAUNG, a town of Hindustan, in the nabob of Oude's territories, seventy miles north-north-west from Lucknow. Long. 80. 15. E. Lat. 27. 40. N.

PEYRERE, Isaac la, an individual remarkable for versatility in his religious opinions, was born at Bordeaux in 1594, being the son of Protestant parents. He entered the service of the Prince of Condé, who was much pleased with the singularity of his genius. From the perusal of St Paul's writings, he took it into his head to maintain that Adam was not the first of the human race; and, to prove this heterodox opinion, he published a book, which was printed in Holland, and entitled *Præadamitæ, sive Exercitatio super versibus*, 12, 13, 14, *cap. xv. Epistolæ Pauli ad Romanos*, 1655, in 4to and 8vo. This work was burned at Paris, and the author imprisoned at Brussels, through the influence of the Archbishop of Malines's grand vicar. The Prince of Condé having obtained his liberty, he travelled to Rome in 1656, and there made to Pope Alexander VII. a solemn renunciation both of Calvinism and Preadamism. But his conversion was not thought to be sincere, at least with regard to this last heresy. His desire to be the head of a new sect is evident; and his book discovers his ambition, for he there pays many compliments to the Jews, and invites them to attend his lectures. Upon his return to Paris, notwithstanding the earnest solicitations of his holiness that he would remain at Rome, he went again into the service of the Prince of Condé, in quality of librarian. Some time afterwards he retired to the seminary *des Vertus*, where he died on the 30th of January 1676, at the age of eighty-two, after the sacraments of the church had been administered to him. Father Simon says, that when he was importuned in his last moments to retract the opinion which he had formed respecting the Preadamites, his answer was, *Hi quæcunque ignorant blasphemant.* His having no fixed opinions in religion is supposed to have proceeded more from a peculiar turn of mind than from corruption of heart; for good nature, simplicity of manners, and humanity, were the leading attributes of his character. "He was," according to Niceron, "a man of a very equal temper, and most agreeable conversation. He was a little too fond, however, of indulging his wit, which sometimes bordered on raillery; but he took care never to hurt or wound the feelings of his neighbour. His learning was extremely limited. He knew nothing either of Greek or of Hebrew, and yet he even ventured to give a new interpretation of several passages in the sacred volume. He prided himself upon his knowledge of the Latin; but, excepting a few poets which he had read, he was by no means an adept in that language. His style is very unequal; sometimes swelling and pompous, at other times low and grovelling." Besides the work already mentioned, he has left behind him, 1. a treatise entitled *Du Rappel de Juifs*, 1643, in 8vo; 2. an Account of Greenland, 1647, in 8vo; 3. an Account of Iceland, 1663, in 8vo; 4. a Letter to Philotimus, 1658, in 8vo, in which he explains the reasons of his recantation.

PEYROUSE, or Perouse, John Francis Galoup de la, the celebrated but unfortunate French navigator, was born at Albi in the year 1741. His father intended to train him up to a maritime life, for which purpose he sent him, when very young, to the marine school, where he became enthusiastically attached to his profession, and ambitious to emulate the fame of the most celebrated navigators. He was appointed midshipman on the 19th of November 1756, and behaved with great bravery in that station, having been severely wounded in the engagement between Hawke and Conflans on the 20th of November 1759. The *Formidable*, in which he served, was taken, after a vigorous resistance; and it is probable that Pérouse reaped some advantage from his acquaintance with British officers. He was promoted, on the 1st of October 1764, to the rank of lieutenant; and as he abhorred a life of ease and idleness, he contrived to be employed in six different ships of war during the peace between Great Britain and France. In 1776 he was promoted to the rank of master and commander. In 1779 he commanded the *Amazone*, belonging to the squadron of Vice-admiral Count d'Estaing; and when that officer engaged Admiral Byron, the duty assigned to La Pérouse was to carry the orders of the admiral to the whole of the line. He afterwards took the sloop *Ariel*, and contributed to the capture of the *Experiment*. In the year 1782, La Pérouse was sent with the *Sceptre* of seventy-four guns, and two frigates of thirty-six guns each, having some troops and field-pieces on board, to destroy the English settlements in Hudson's Bay; a task which he easily accomplished, as there was nothing on shore to oppose the smallest force. When he had destroyed the settlements, having learned that some of the English had fled at his approach into the woods, he generously left them provisions, and arms to defend themselves against the savages. In the year 1785, he was appointed to the command of some ships commissioned for a voyage round the world, which unfortunately proved his last. Of this voyage, as far as it was accomplished, full accounts have already been published, from which it is manifest that Pérouse was admirably qualified to discharge such a trust. He was an experienced and skilful seaman; skilled in mathematical and physical science; uncorrupted by that false philosophy which disgraced many of his attendants; and capable of the utmost perseverance in every commendable pursuit. To these valuable qualities he added caution and courage, with a disposition truly benevolent towards the savages whom he visited. Most of the calamities attendant on the voyage, with the exception of the last, were occasioned by the disobedience of his officers, or their neglecting to follow his advice. The last despatches received from this excellent man were dated from Botany Bay, the 7th of February 1788; but since that period no authentic account of him has ever been obtained.

PEYRUSSE, a city of France, in the department of Aveiron and arrondissement of Villefranche. It stands on an elevation, at the base of which flows the river Diège. It has a hospital, and 910 houses, with 6350 inhabitants. Long. 1. 55. E. Lat. 44. 36. N.

PEYTAHN, a district of Northern Hindustan, with a mountainous irregular surface, much covered with jungle. It is tributary to the rajah of Nepaul, and is situated about the twenty-ninth degree of north latitude. Also a town in the Nepaul territories, the capital of a district of the same name. Long. 82. 15. E. Lat. 29. 4. N.

PEZAY, N. Masson, Marquis de, born at Paris, where he early applied himself to the study of letters, and afterwards went into the army. He was made a captain of dragoons, and had the honour of giving some instructions in tactics to the ill-fated Louis XVI. Being appointed inspector-general of some coasting vessels, he repaired to the maritime towns, and executed his commission with more care and attention than was to be expected from a votary of the muses. But as he had at the same time displayed too much haughtiness, a complaint was made against him to the court, and he was banished to his country-seat, where he died soon afterwards, in the beginning of 1778. He was the intimate friend and companion of Dorat, whom he had studied, and successfully imitated; but his poems have more delicacy, and are less disfigured with trifling conversations of gallantry. He left behind him, 1. a Translation of Catullus, which is not much esteemed; 2. Les Soirées Helvetiennes, Alsaciennes, et Franc-Comtoises, 1770, in 8vo; 3. Les Soirées Provençales, in manuscript; 4. La Rosière de Salency, a pastoral in three acts, which was performed with success in the Italian theatres; 5. Les Campagnes de Mailebois, in three vols. 4to, and a volume of maps.

PEZENAS, a city of France, in the department of Hérault and arrondissement of Beziers. It is situated in a fine district on the river Peine, near to its junction with the Hérault. It contains 1600 houses, with 8640 inhabitants, who are employed in silk-mills, in tanneries, and in making brandy, soap, and other commodities. Long. 3. 21. E. Lat. 43. 28. N.

PFKOW, or Pleskow, a government or stadtholderate of the empire of Russia. It is formed out of a part of what was formerly Great Russia, or rather of the grand principality of Novogorod. It extends in north latitude from 55. 55. to 58. 4., and in east longitude from 27. 15. to 32. 1., having a superficies of 22,990 square miles. It is divided into eight circles, and comprehends ten cities or towns, and four hundred and thirty-five parishes. The population amounts to about 800,000 persons. The climate is severely cold, and the soil not fertile. The surface is covered with gentle elevations, woods, rivers, lakes, morasses, and heaths. The chief products, beyond what domestic consumption requires, consist of pitch, tar, flax, hemp, planks, masts, and flax-seed, which are conveyed to St Petersburg. The capital is the city of the same name situated on the Welikaja, is the see of an archbishop, with a cathedral, and fifty-nine other churches. It contains 1480 houses, constructed for the most part of wood, and about 10,000 inhabitants, whose chief trade is making sail-cloth and linen, and dealing in the raw products of their district. Long. 29. 5. E. Lat. 57. 40. N.

PHÆDO, a native of Elis, was the founder of the Eliac sect of philosophy, and the person whose name Plato inscribed in one of his most celebrated dialogues. The exact date of his birth and death is unknown, but he flourished B. C. 399. By the fortune of war he was taken prisoner, and reduced to a state of slavery. He was brought to Athens, where he became known to Socrates, who admired his talents so much that he caused Alcibiades or Crito to release him from servitude. He then became one of the most devoted attendants on his benefactor. It appears that he was not at all satisfied with the manner in which he was introduced by Plato into his dialogue; and he used to declare publicly that he had never spoken in that way, and that he had never heard Socrates use the language which Plato put into his mouth. Plato was so much offended with this proceeding, that, in revenge, he threatened to bring a lawsuit against Phædo, to prove that he had never received his freedom. (Athenæus, xi. 505, e; 507, c.) He composed several dialogues, the titles of which were, Zopyrus, Simon, and several which it was doubtful if they belonged to him; Nicias, Antimachus, Medus, ascribed by some to Æschines, by others to Polyænus; Sythici Sermones, ascribed also to Æschines; and three others quoted by Suidas. He was succeeded in his school by Pleistanus of Elis, Pleistanus by Stilpo, Stilpo by Menedemus of Eretria and Asclepiades of Phlius. (Diogenes Laertius's *Life of Phædo.*)

PHÆDRA, in fabulous history, was a daughter of Minos and Pasiphaë, who married Theseus, by whom she became the mother of Acamas and Demophoon. They had already lived for some time in conjugal felicity, when Venus, who hated all the descendants of Apollo, because he had discovered her amours with Mars, inspired Phædra with the strongest passion for Hippolytus, the son of Theseus by the Amazon Hippolyte. This passion she long attempted to stifle, but in vain; and therefore, in the absence of Theseus, she addressed Hippolytus with all the impatience of desponding love. He rejected her with horror and disdain. Incensed at the reception which she had met, she resolved to punish his coldness and refusal; and on the return of Theseus she accused Hippolytus of attempts upon her virtue. He listened to her accusation, and, without hearing Hippolytus's defence, banished him from his kingdom, and implored Neptune, who had promised to grant three of his requests, to punish him in an exemplary manner. As Hippolytus fled from Athens, his horses were suddenly terrified by a sea monster, which Neptune had sent on the shore; and he was thus dragged through precipices and over rocks, trampled under the feet of his horses, and crushed under the wheels of his chariot. When his tragical end became known at Athens, Phædra confessed her crime, and hung herself in despair, unable to survive one whose death had been occasioned by her licentiousness and falsehood. The death of Hippolytus, and the infamous passion of Phædra, form the subject of a tragedy of Euripides, and also of one by Seneca. She was buried at Trœzene, where her tomb was still to be seen in the time of the geographer Pausanias, near to the temple of Venus, which she had built to render the goddess favourable to her passion. Close by her tomb was a myrtle, the leaves of which were full of small holes, which, it was reported, Phædra had done with a hair pin, when the vehemence of her passion had rendered her melancholy and almost desperate. She was represented in a painting in the temple of Apollo at Delphi, as suspended in the air, whilst her sister Ariadne stood close by, with her eyes fixed upon Phædra.

Phædrus.

PHÆDRUS, the author of five books of fables, in Latin iambic measure, was a native of Thrace or Macedonia, and brought at a very early age to Rome, where he became the slave of Augustus, and from whom he subsequently received his freedom. The few facts that we know respecting his personal history are to be collected from his fables, as he is noticed by no earlier writer than Avianus, unless, perhaps, Martial may allude to him in one of his epigrams (iii. 20). If he really existed at this early period, it is strange that he should have been unknown to Seneca (*Cons. ad Polyb.* 27). By his long residence at Rome, Phædrus acquired a complete acquaintance with the language, and wrote it with as much ease as he could have done that of his own country. In the reign of Tiberius, he excited the wrath of Sejanus, and was banished by him, though for what cause we are nowhere distinctly informed. Under Caligula we find him in hopes of being reinstated in his position at court, through the influence of Eutychus. Part at least of these fables must have been written in the latter years of the poet, and not published till after the death of Sejanus. Schwabe, who has examined this point with great diligence, thinks that the first two books were written after the departure of Tiberius to Caprea, the third under Caligula, and the fourth and fifth under Claudius. One part of these fables consists of very happy translations of the Greek fables of Æsop into the Latin language, or imitations of them in verse, similar to that employed in the translations. The other part seems to have been original, or at least we have no longer the writers from whom he borrowed his subjects. The style is pure, the language remarkably correct, and the whole is written with simplicity and ease. Yet many have doubted whether these fables can be considered as the genuine productions of Phædrus, the freedman of Augustus, as we have so few manuscripts of the work, and as Seneca was evidently unacquainted with it. Some ascribe them to the pen of Nicolaus Perotti, archbishop of Manfredonia, who lived about the middle of the fifteenth century; but, in later times, the discovery of some manuscripts, one of which is considered as of the tenth century, has proved the incorrectness of such a supposition. The best edition of the works of Phædrus is that by Schwabe, two vols. Brunswick, 1806, 8vo.

PHÆNOMENON, in philosophy, denotes any remarkable appearance, whether in the heavens or in the earth, and whether discovered by observation or by experiment.

PHAETON, in fabulous history, was the son of Phœbus, and Clymene, one of the Oceanides. According to Hesiod and Pausanias, he was son of Cephalus and Aurora; or, according to Apollodorus, of Tithonus and Aurora. He is, however, more generally acknowledged to have been the son of Phœbus and Clymene. He was naturally of a lively disposition, and of a handsome figure. Venus became enamoured of him, and intrusted him with the care of one of her temples. But this distinguishing favour of the goddess rendered him vain and aspiring; and when Epaphus, the son of Io, had told him, to check his pride, that he was not the son of Phœbus, Phaeton resolved to know his true origin, and at the instigation of his mother he visited the palace of the Sun. He begged Phœbus, that, if really his father, he would give him incontestable proofs of his paternal tenderness, and convince the world of his legitimacy. Phœbus received him with great tenderness, and swore by Styx to grant whatever he requested, as a proof of his acknowledging him as his son. The youth boldly asked the direction of the chariot of the sun for one day. His father, grieved and surprised at this demand, used every argument to dissuade him from the rash attempt; but all was in vain; and being by his oath reduced to submit to the obstinacy of Phaeton, he intrusted him with the reins, after he had directed him how to use them. The young adventurer was, however, soon made sensible of his madness. Unable to guide the fiery steeds, he slackened the reins, upon which Jupiter, to prevent his consuming the heavens and the earth, struck him with a thunderbolt, and hurled him from his seat into the river Eridanus or Po. His sisters Phaëthusa, Lambetia, and Phœbe, lamenting his loss upon its banks, were changed by the gods into black poplar trees; and Cygnus, king of Liguria, also grieving at his fate, was transformed into a swan. The poets say, that whilst Phaeton was driving the chariot of his father, the blood of the Ethiopians was dried up, and their skin became black; a colour which is still preserved amongst the greater part of the inhabitants of the torrid zone. The territories of Libya were also, they tell us, parched up, on account of their too great vicinity to the sun; and ever since, Africa, unable to recover her original verdure and fruitfulness, has exhibited a sandy country and uncultivated waste. According to those who explain this poetical fable, Phaeton was a Ligurian prince, who studied astronomy, and in whose age the country situated on the Po was visited with uncommon heats.

PHAK, a district of Afghanistan, in the province of Cashmere. It is a romantic country, containing a beautiful lake, on which are some artificial islands. It is bounded on the west by the river Jhylum, and is situated in the thirty-fifth degree of north latitude.

PHALANX, in Grecian antiquity, a dense military formation, originally invented by the Greeks, but finally perfected by the Macedonians, under whom it became an invincible order of battle. See the article Army, in which the leading characteristics of this remarkable formation are fully explained.

PHALARIS, the tyrant of Agrigentum, of whom only a few facts have been transmitted to us, upon which any dependence can be placed. Ancient writers are not agreed as to the precise period when he began to reign, but Eusebius fixes the commencement of it B. C. 570, and his death B. C. 555. His father's name was Leodamas, a native of Astypalæa, an island in the Ægean Sea, where Phalaris was born. A dream of his mother is said to have prognosticated the cruelty of her unborn son. (Cic. *Div.* i. 23.) When he was grown to manhood, he made an attempt to seize upon the government of his native country, but was obliged to fly. He took refuge at Agrigentum, where he contrived to ingratiate himself with the people, and by a stratagem (Polyæn. v. 1) got possession of the supreme authority, which he exercised at first with much moderation. The Agrigentines, however, refused to submit quietly to his sway, and Phalaris found himself obliged to maintain by severity that power which he had so unjustly acquired. It is not unlikely that the ancients gave an exaggerated account of his cruelties, with the view of inspiring a hatred of tyranny. Athenæus speaks of his roasting children alive, and Aristotle states that he actually ate them; but such accounts can scarcely be credited. Perillus, an Athenian artist, is said to have constructed a brazen bull, in which the victims of Phalaris might be roasted; and when he expected to have been highly rewarded, the tyrant ordered him to be shut up in his own horrible machine. This story was doubted by Timæus (*Schol. Pind. Pyth.* i. 185), but Diodorus Siculus asserts its truth (xiii. 90, xix. 108). When Agrigentum was taken by the Carthaginians, they carried the bull to Carthage, and when that city was destroyed by Scipio Africanus, B. C. 146, it was presented by him to the Agrigentines. (Cic. *Verr.* iv. 33.) Authors are not agreed as to the mode of his death, but the most probable opinion is that the Agrigentines, tired of his cruelties, stoned him to death. (*Off.* ii. 7.) We possess a collection of letters under the name of Phalaris, which Boyle, who has edited them, tries to prove the genuine productions of the tyrant; but there can be no doubt that they were written by some of the later sophists. They were published for the first time by Justinopolitanus, at Venice, 1498, in 4to. The best editions are those of Oxford, 1695, 1718, in 8vo, with a Latin translation, notes, and a dissertation of Boyle on the life of Phalaris; and that of Groningen, 1777, in 4to, which was begun by Lennep and finished by Walkenaer. (See the Dissertation of Dodwell, *De Ætate Phalaridis;* and the Answer of Bentley.)

PHALERÆ, amongst the ancient Romans, were military rewards bestowed for signal acts of bravery. Authors are not agreed whether the *phaleræ* were a suit of rich trappings for a horse, or golden chains something like the *torques*, but so formed as to hang down to the breast, and display a greater profusion of ornament. The latter opinion appears to be the more prevalent one, but both are perhaps true.

PHALEUCIAN Verse, in ancient poetry, a kind of verse consisting of five feet; the first of which is a spondee, the second a dactyl, and the three last trochees.

PHANTASIA was the daughter of Nicarchus of Memphis in Egypt. It has been supposed that she wrote a poem on the Trojan war, and another on the return of Ulysses to Ithaca, compositions from which Homer is supposed to have copied the greater part of his Iliad and Odyssey when he visited Memphis, where they were deposited.

PHANTASM, a term sometimes used as synonymous with the idea or notion retained in the mind, of an external object. See Metaphysics.

PHANTASY, or Fancy, the imagination, one of the powers of the mind, by which the species of objects received through the external organs of sense are retained, recalled, further examined, and either compounded or divided. See Metaphysics.

PHANUEL, of the tribe of Asher, the father of a holy widow and prophetess called Anna, who was in the temple when our Saviour was presented there by his parents (Luke, ii. 36, 37, 38).

PHAON, a young man of Mitylene, in the island of Lesbos, who received from Venus, as fable reports, an alabaster vase filled with an essence which had the virtue of conferring beauty. He had no sooner anointed his body with it than he became the most beautiful of men. The ladies of Mitylene fell desperately in love with him; and the celebrated Sappho threw herself from the crest of a precipice because he refused to encourage her passion.

PHARAMOND is the name given by the generality of historians to the first king of France. He is said to have reigned at Trèves, and over a part of France, about the year 420, and to have been succeeded by his son Clodion; but the account which is given of these two princes is very uncertain. It is probable that Pharamond was no more than a general of an army, or the head of a military society of Franks, who were masters of their persons and their fortunes. Gregory of Tours, the author of a curious history of the Franks, appears to have entertained this opinion.

PHARAOH, a generic name of the kings of Egypt, belonging to the ancient native dynasties. Josephus says, that all the kings of Egypt, from Menes the founder of Memphis, who lived several ages before Abraham, always bore the name of Pharaoh, down to the time of Solomon, that is, for more than three thousand years. He adds, that in the Egyptian language the word *Pharaoh* signifies *king;* and that those princes only assumed this name when they ascended the throne, at which time they also relinquished their former names. Hence it comes to pass, says Josephus, that Herodotus names none of the kings of Egypt after Menes the builder of Memphis, although he had three hundred and thirty successors, because they had all the name of Pharaoh; but because it did not pass to women, he names an Egyptian queen, Nicaule, who succeeded them. Lastly, Josephus concludes, from the ancient records of his nation, that after the age of Solomon no king of Egypt bore any longer the name of Pharaoh.

But Josephus is not accurate in this passage. It is true, Herodotus says that Menes was the first king of Egypt, and the founder of Memphis; that there were three hundred and thirty kings after him in that country; and that after them there was a queen called Nicotris, and not Nicaule, as Josephus writes it. But it is not true that these kings had no other name but that of Pharaoh. Herodotus says expressly, that in the books of the Egyptian priests were inserted the names and the catalogue of three hundred and thirty kings; that in this number of three hundred and thirty there were eighteen Ethiopians, and a woman, who was a foreigner, called Nicotris; and that all the others were Egyptians. These princes therefore had every one his proper name mentioned in the catalogue of the Egyptian kings. Thus, in the fragments of Manetho, we find that every king of Egypt had a name peculiar to himself; whilst the name of Pharaoh occurs only in Scripture. What Josephus adds concerning Queen Nicaule, or Nicotris, whom he pretends to be the same as the queen of Sheba, of whom mention is made in Scripture, is entirely fabulous; and as to his statement, that since the time of Solomon the kings of Egypt have no longer borne the name of Pharaoh, it is manifestly false, since we still find his name in the second book of Kings, under Hezekiah;[1] under Josiah,[2] where this name is joined to that of Nechoh, which was the proper name of the prince; under Jehoiakim;[3] and likewise in the writings of Isaiah, Jeremiah, and Ezekiel, who were much later than Solomon. It is probable, indeed, that the Egyptians gave the name of Pharaoh to their kings as long as the Egyptian language was in common use, and as long as their kings were of their own nation; but after the conquest of Egypt by Alexander the Great, when the Greeks introduced their language and their government, the name of Pharaoh was no longer known amongst them. Indeed it had ceased to be so from the date of the Persian invasion under Cambyses. The first prince known to us by the name of Pharaoh was he in whose time Abraham went down to Egypt, when Sarah, who passed only for Abraham's sister, was by the command of Pharaoh brought to his palace in order to become his wife. But the Lord smote Pharaoh and his family with great infirmities, and gave him to know that she was Abraham's wife; upon which Pharaoh sent for Abraham, restored him his wife, and at the same time gave orders that he should be conducted out of Egypt, with every thing that belonged to him.

Pharaoh.

The second Pharaoh spoken of in the Scripture is he who reigned when Joseph arrived there. This prince or his successor had the mysterious dream of the fat and the lean kine, and the seven full and barren ears of corn, which Joseph explained so much to his satisfaction that he made him governor of his house and of all Egypt, reserving only to himself the name of king. This is the same Pharaoh who sent for and entertained the patriarch Jacob and his family in Egypt, and gave them the land of Goshen for their habitation.

The third Pharaoh mentioned in Holy Writ is he who persecuted the Israelites. Moses tells us that he was a new king, and had no knowledge of Joseph. This prince, observing that the Israelites had become numerous and powerful, resolved to depress them by hardship and labour, and set cruel and pitiless taskmasters over them. But the more he oppressed them the faster they multiplied; insomuch that he gave orders to the Egyptian midwives, who assisted the Hebrew women in their labour, to put all the male children to death, and to save alive the females only. But this command was not strictly executed. The midwives feared the Lord, and preserved alive not only the female children, but also the males. Pharaoh, finding this project did not succeed to his wishes, published a decree that all the male children born of Hebrew women should be thrown into the Nile, and that only the females should be spared. This order was rigorously executed; yet, by the providence of God, Moses was preserved, and even brought up in Pharaoh's court, by his own daughter, who by chance had found the child, as he was exposed amongst the rushes of the Nile.

Moses being grown up, and having killed an Egyptian who had abused an Hebrew, was obliged to fly from Egypt in order to avoid that death which Pharaoh had threatened him withal. But several years afterwards, being about eighty years old, he returned by order from God, and performed mighty miracles before Pharaoh. There is a good deal of probability that this Pharaoh before whom Moses appeared, and in whose sight he smote Egypt with so many plagues, was a different person from him who would have laid hands on the Jewish chief after he had slain the Egyptian. This Pharaoh having been at last compelled to send away the Hebrews, and to suffer them to quit Egypt, soon repented of the leave he had given, and pursued them at the head of his army with his chariots. But he was drowned in the Red Sea, in which he had rashly entered in the eagerness of pursuit. Several historians pretend to give the name of this Pharaoh; some, as Apion, calling him Amosis or Amasis; Eusebius, Chenchris; and Usher, Amenophis; but we may be assured that there is nothing certain in all this.

The fifth Pharaoh known to us is he who afforded protection to Hadad, son of the king of Edom, and who gave him to wife the sister of his own queen, enriched him with lands, and brought up his son Genubah in his own court. Hadad returned to Idumæa after the death of David.

The sixth Pharaoh is he who gave his daughter in marriage to Solomon, king of the Hebrews (1 Kings, iii. 1), and who, having taken Gezer, set it on fire, drove out the Canaanites, and gave it as a present to Solomon, in lieu of a dowry to his daughter, whom he had married to this prince (1 Kings, ix. 16).

---

[1] 2 Kings, xviii. 21.

[2] Ibid. xxiii. 29, 33.

[3] Ibid. xxiii. 34, 35.

The seventh is Shishak, who entertained Jeroboam in his dominions, a rebellious subject of Solomon, and offered him a refuge in opposition to the king his master. The same Shishak declared war against Rehoboam the son and successor of Solomon, besieged and took Jerusalem, and carried away all the king's treasures, and those of the house of God, particularly the golden bucklers which Solomon had made.

The eighth is that Pharaoh with whom Hezekiah formed a league against Sennacherib, king of Assyria, in the year of the world 3290. This Pharaoh is probably the same whom Herodotus names Sethon, priest of Phtha, who came to meet Sennacherib before Pelusium, and to whose assistance Phtha sent an army of rats, which gnawed the bowstrings and the thongs of the bucklers of Sennacherib's soldiers.

The ninth is Pharaoh Nechoh, or Nechos, the son of Psammeticus, who made war on Josiah, and conquered him. Herodotus also mentions this prince.

The tenth of this name is Pharaoh Hophrah, who entered into an alliance with Zedekiah, king of Judah, and attempted to march to his assistance against Nebuchadnezzar, king of Chaldæa. It was against this Pharaoh that Ezekiel pronounced several of his prophecies.[1] He is called Apries in Herodotus,[2] and is also mentioned in Habakkuk.[3]

PHARAON, or PHARO, is the name of a game of chance. The principal rules of pharo are as follow: The banker holds a pack consisting of fifty-two cards; he draws all the cards, one after the other, and lays them down alternately at his right hand and his left; then the ponte may at his pleasure set one or more stakes upon one or more cards, either before the banker has begun to draw the cards, or after he has drawn any number of couples. The banker wins the stake of the ponte when the card of the ponte comes out in an odd place on his right hand, but loses as much to the ponte when it comes out in an even place on his left hand. The banker wins half the ponte's stake when it happens to be twice in one couple. When the card of the ponte being but once in the stock happens to be the last, the ponte neither wins nor loses; and the card of the ponte being but twice in the stock, and the last couple containing his card twice, he then loses his whole stake. Demoivre has shown how to find the gain of the banker in any circumstance of cards remaining in the stock, and of the number of times that the ponte's card is contained in it. Of this problem he enumerates four cases, viz. when the ponte's card is once, twice, three, or four times in the stock. In the first case, the gain of the banker is $\frac{1}{n}$, n being the number of cards in the stock. In the second case, his gain is $\frac{\overline{n-2}\times y}{n\times\overline{n-1}}+\frac{2}{n\times\overline{n-1}}$, or $\frac{\frac{1}{2}n+1}{n\times\overline{n-1}}$, supposing $y=\frac{1}{2}$. In the third case, his gain is $\frac{3y}{2\times\overline{n-1}}$, or $\frac{3}{n\times\overline{n-1}}$, supposing $y=\frac{1}{2}$. In the fourth case, the gain of the banker, or the loss of the ponte, is $\frac{2n-5}{\overline{n-1}\times\overline{n-3}}\,y$, or $\frac{2n-5}{2\times\overline{n-1}\times\overline{n-3}}$, supposing $y=\frac{1}{2}$. Demoivre has calculated a table, exhibiting the gain or loss in any particular circumstance of the play; and he observes, that at this play the least disadvantage of the ponte, under the same circumstances of cards remaining in the stock, is when the card of the ponte is but twice in it, the next greater when three times, the next when once, and the greatest when four times. He has also demonstrated, that the whole gain per cent. of the banker, upon all the money that is adventured at this game, is L.2. 19s. 10d. (See Demoivre's *Doctrine of Chances.*)

PHARISEES, a famous sect amongst the Jews, who distinguished themselves by their zeal for the traditions of the elders, which they derived from the same fountain with the written word itself; pretending that both were delivered to Moses from Mount Sinai, and were therefore of equal authority. From their rigorous observance of these traditions, they looked upon themselves as more holy than other men; and therefore separated themselves from those whom they thought sinners or profane, so as not to eat or to drink with them. Hence, from the Hebrew word *pharic*, which signifies to separate, they received the name of *Pharisees* or *Separatists*.

This sect was one of the most ancient and considerable amongst the Jews; but its origin is not very well known. However, it was in great repute in the time of our Saviour, and must have had its origin at the same time with the traditions; in fact, they grew together, until at length they had so far gained ground that the traditional law swallowed up the written, and those who were the propagators of it included the bulk of the Jewish nation.

The extraordinary pretences of the Pharisees to righteousness drew after them the common people, who held them in the highest esteem and veneration. Our Saviour, however, frequently charges them with hypocrisy, and with making the law of God of no effect through their traditions.[4] Several of these traditions are particularly mentioned in the gospel; but they had a vast number more, which may be seen in the Talmud, the grand object of which is to explain and enforce those which this sect required to be believed and observed.

The Pharisees, contrary to the opinion of the Sadducees, held a resurrection of the dead, and the existence of angels and spirits. But, according to Josephus, this resurrection of theirs was no more than a Pythagorean resurrection, that is, of the soul only, by its transmigration into another body, and being born anew with it; and from this they excluded all who were notoriously wicked, being of opinion that the souls of such persons were consigned to a state of everlasting wo. As to lesser crimes, they held that these were punished in the bodies which the souls of those who committed them were next sent into.

Josephus, however, either mistook the faith of his countrymen, or, which is equally probable, wilfully misrepresented it, in order to render their opinions more respected by the Roman philosophers, whom he appears on every occasion to have been desirous to please. The Pharisees had many pagan notions respecting the soul; but Bishop Bull, in his *Harmonia Apostolica*, has clearly proved that they held a resurrection of the body, and supposed a certain bone to remain uncorrupted in order to furnish the matter out of which the resurrection of the body was to be effected. They did not, however, believe that all mankind were to be raised from the dead. A resurrection was the privilege of the children of Abraham alone, who were all to rise on Mount Zion; their incorruptible bones, wherever they might be buried, being carried to that mountain below the surface of the earth. The state of future felicity, in which the Pharisees believed, was in fact exceedingly gross. They imagined, that men in the next world, as well as in the present, were to eat and drink, and enjoy the pleasures of love, each being reunited to his former wife. Hence the Sadducee, who believed in no resurrection, and supposed that our Saviour taught it as a Pharisee, shrewdly urged

Pherecrates.

the difficulty of disposing of the woman who had in this world been the wife of seven husbands. Had the resurrection of Christianity been of the Pharisaical kind, this difficulty would have been insurmountable; and accordingly we find the people, and even some of the Pharisees themselves, struck with the manner in which our Saviour removed it.

This sect appears to have had some confused notions, derived probably from the Chaldæans and Persians, respecting the pre-existence of souls; and hence it was that Christ's disciples asked him, concerning the blind man, "Who did sin, this man or his parents, that he was born blind?" And when the disciples told Christ, that some said he was Elias, Jeremias, or one of the prophets, the meaning of this can only be, that they thought he had come into the world with the soul of Elias, Jeremias, or some other of the old prophets, transmigrated into him. Like the Essenes, the Pharisees held absolute predestination, and like the Sadducees, free-will; but how they reconciled these incompatible doctrines is nowhere sufficiently explained. The sect of the Pharisees was not extinguished by the ruin of the Jewish commonwealth. The greater part of the modern Jews are still of this sect, and as much devoted to traditions or the oral law as their ancestors ever were.

PHARMACI were two persons employed in the lustration or purification of cities. Some say that they were both men; but others maintain, that a man to represent the males, and a woman to represent the females, performed this office. They offered sacrifice, and wore figs about their necks; those of the men being blackish, and those of the women white. Figs were an emblem of fertility, which they doubtless prayed for on these solemn occasions.

PHARMACEUTICAL, any thing connected with pharmacy, or the processes employed in the preparation of medicines.

PHARMACOCHEMIA, an obsolete term, denoting that part of the chemical art which treats of the preparation of medicines, and used in contradistinction to that of chemistry, which was wholly employed about the transmutation of metals by means of the philosopher's stone, and hence called *spagirico-chemia*.

PHARMACOPŒIA (from φαρμακον, *remedy*, and ποιειν, *to make*), means a dispensatory, or a treatise describing the preparations of the several kinds of medicines, with their uses, modes of application, and so forth.

PHARMACOPOLA, or PHARMACOPEIUS, an apothecary, or a person who prepares and sells medicines. This word, which is rarely used except in the way of ridicule, is composed of φαρμακον, *medicine*, and πολειν, to *sell*.

PHARMACUM, φαρμακον, a medicine or medicament, either of a salutary or deleterious quality.

PHARMACY, the art of preparing, preserving, and compounding medicines. See MATERIA MEDICA, and THERAPEUTICS.

PHAROS, a small oblong island, adjoining the continent of Egypt, and over-against Alexandria. On this island stood a lighthouse of the same name, having four sides, each a stadium in length, and a tower so elevated as to be seen nearly a hundred miles off. Some affirm that each of its four corners rested on a large sea-crab of hard transparent stone brought from Ethiopia or Memphis; but others imagine that the crabs were only added externally to the base by way of ornament, or as emblematical of its situation and use. The architect was Sostrates the Cnidian, as appears by an inscription engraved upon the tower, under Ptolemy Philadelphus, who expended upon it eight hundred talents. On account of the port of Alexandria, the entrance to which was difficult and dangerous, the Pharos was called "the key of the Egyptian Sea," and even of Egypt itself; and Pharos, from being originally a proper name, at length became an appellative to denote all kinds of lighthouses.

PHAROS, a lighthouse or pile of building, raised near a port, where fire is kept burning in the night, to guide and direct vessels near at hand. The pharos of Alexandria, built on the island of Pharos, was anciently so famous that it communicated its name to all the rest. This magnificent tower consisted of several stories and galleries, with a lantern at the top, in which a light being kept continually burning, might be seen many leagues at sea, and along the coast. It was accounted one of the seven wonders of the world. It was built by the celebrated architect Sostrates, a native of Cnidus, or, according to some, by Deiphanes, the father of Sostrates, and cost Ptolemy Philadelphus eight hundred talents. See SEA-LIGHTS.

PHARSALIA, in *Ancient Geography*, a town of the Phthiotes, a district of Thessaly, near Pheræ and Larissa. To this last place Pompey fled from the plains of Pharsalus; it is watered by the river Enipeus, which falls into the Apidamus, and both together unite with the Peneus. Between Pharsalia and Enipeus Pompey drew up his men at the decisive battle of Pharsalia. See ROME.

PHASES, in *Astronomy*, a word formed from the Greek verb φαινω, *to appear*, are the several appearances or quantities of illumination of the moon, Venus, Mercury, and the other planets. See ASTRONOMY.

PHEBE, a deaconess of the port of Corinth, called Cenchrea. St Paul had a particular esteem for this holy woman; and Theodoret thinks the apostle lodged for some time at her house, whilst he continued at or near Corinth. It is thought that she brought to Rome the epistle he addressed to the Romans, in which she is recommended in so advantageous a manner. The apostle says (Rom. xvi. 1, 2), "I commend unto you Phebe our sister, who is a servant of the church which is at Cenchrea, that ye receive her in the Lord, as becometh saints, and that ye assist her in whatsoever business she hath need of you; for she hath been a succourer of many, and of myself also." Some moderns have advanced a notion that Phebe was the wife of St Paul; but none of the ancients has said any thing to justify such an opinion. It is generally supposed that, in quality of deaconess, she was employed by the church in some ministrations suitable to her sex and condition; as to visit and instruct the Christian women, to attend them in their sickness, and to distribute alms amongst them.

PHEGOR, or PEOR, a deity worshipped at a very early period by the Midianites and Moabites, and probably by all the other tribes who then inhabited Syria. Much has been said concerning the functions of this god, and the rank which he held amongst the Pagan divinities; and many conjectures have been formed concerning the origin of his name. But most of these appear to have no better foundation than the senseless dreams of the Jewish rabbin. *Phegor*, or *Peor*, is undoubtedly the same with the Hebrew word *pechor*, which signifies "aperuit," and probably refers to the prophetic influence always attributed to the solar deity, by which he *opened* or *discovered* things to come. Accordingly we find Phegor or Peor generally joined to *Baal* or *Bel*, which was the Syrian and Chaldæan name of the sun after he became an object of worship; and hence *Bel-phegor* must have been the sun worshipped by some particular rites, or under some particular character.

PHENGITES, amongst the ancients, the name of a beautiful species of alabaster. It is a rude irregular mass, very brittle and friable, but of a brightness superior to that of most other marbles, and excelling them all in transparency.

PHEONS, in *Heraldry*, the barbed heads of darts, arrows, or other weapons.

PHERECRATES, a writer of the ancient comedy, was a native of Athens, and contemporary of Plato, Aristophanes, Phrynichus, and Eupolis. According to Suidas, he was a soldier in his youth, but afterwards attached himself to the stage, and became one of the most successful dramatic writers. We know that he exhibited a play entitled Savages ('Αγριοι), B. C. 420 (Plato, Protag. 327, d; Athen. v. 218, d). He invented a species of verse, called from his name Pherecratian, consisting of a spondee, and the two last feet of an hexameter line. Suidas attributes seventeen plays to him, referring probably to those only which he considered as genuine, since the titles of twenty are found in Athenæus. The fragments of Pherecrates have been collected by Hertel in *Vetustissimorum Comicorum Sententiæ*, p. 340–57. Of all the fragments of Pherecrates, the most remarkable is that entitled Cheiron, in which he introduces music, clad in rags, to which state she says she has been reduced by Melanippides, Phryoris, and Timotheus, the authors of some innovations on that art. (See *Mém. de l'Acad. des Inscript.* xv. 330.)

PHERECYDES, a Greek philosopher of the island of Syros, one of the Cyclades, was the son of Badys, and the pupil of the celebrated Pittacus of Mitylene. The exact date of his birth and death is unknown, but he flourished B. C. 544, being a contemporary of Thales, Anaximenes, Anacreon, and Hipponax. There is some doubt whether he is not the astronomer Pherecydes who constructed a sun-dial at Syros; but as this person is said to have been the master of Thales, it is more likely that there was another of an earlier date. The philosopher was the instructor of Pythagoras, and is said to have foretold earthquakes by observing the movement of water in wells (Cic. *Tus.* i. 16; *Div.* i. 50). There were various accounts respecting his death, but most are agreed that he was devoured by worms and insects like Sylla; and the reason assigned was, that he had offended Apollo, because he said that he lived very happily though he had never sacrificed to the gods. (Ælian. *V. H.* iv. 28.) Pherecydes was the author of a work on Nature and on the Gods, being the first of the Greeks who wrote on this subject. (Diogenes Laertius, *Life of Pherecydes.*) The fragments of Pherecydes have been collected by Auguste Wolf, in the first part of his *Litterarische Analecten*, Berlin, 1817.

PHERECYDES, an historian of the island of Leros, in the Ægean Sea, is satisfactorily proved by Vossius (*De Hist. Græcis*, p. 444) to be the same who is called an Athenian by some. He flourished B. C. 480, in the reign of Darius Hystaspes, and preceded Herodotus by a few years. He is said to have made a collection of the poems of Orpheus, to have written on the genealogy of the gods (*Theogoneia*) in ten books, on the mythological part of the history of Athens ('Αυτόχθονας) in ten books, and moral maxims in hexameter verse. The fragments of Pherecydes, along with those of Acusilaüs, have been published by Sturz, Gera, 1789, 1798, with a learned dissertation.

PHIDIAS, a celebrated Greek statuary, was the son of Charmidas, a native of Athens, and flourished B. C. 444, in the age of Pericles, being the contemporary of Alcamenes, Critias, Hegias, and Nestocles. In his representations of the gods he was so successful that it was said he must either have visited heaven, or the gods must have descended to him. (Analect. Brunck. vol. ii. p. 225.) One of the finest of his works was his statue of Jupiter Olympius, in the temple of Olympia. It was made of ivory and gold, and was of such colossal size, that being seated, it appeared, that if it rose up, it could carry away the roof. Being asked by his brother Panænus what model he had followed in his representation of the god, Phidias referred him to the portrait of Jupiter given by Homer (*Iliad.* i. 528–530). His statue of Minerva at Athens was also very much admired, and the shield of the goddess presented a fine specimen of bas-relief. Along the edge was sculptured the battle of the Amazons, and in the hollow part the battle of the gods and giants. (Strab. viii. 353; Plin. xxxvi. 4, 7; Paus. v. 10, 2; Quint. xii. 10, 1; Val. Max. iii. 7, 4. In the time of Pliny, there was a Venus by him, in the portico of Octavia; and at present there is a magnificent colossal statue of a man curbing a fiery steed, placed before the palace of the Vatican at Rome, which is inscribed with the name of Phidias, but the group has no right to be considered as his production. Phidias was the teacher of Alcamenes, Agoracritus, and Colotes. (Plin. xxxiv. 19, 1–5, xxxv. 34, 1.)

PHIDITIA, in Grecian antiquity, feasts celebrated with great frugality at Sparta. They were held in the public places and in the open air. Rich and poor assisted at them equally, and upon the same footing; their design being to keep up peace, friendship, good understanding, and equality amongst the citizens, great and small. It is said that those who attended this feast brought each a bushel of flour, eight measures of wine, five pounds of cheese, and two pounds and a half of figs, with some money.

PHILA, in *Mythology*, one of the attributes of Venus, which distinguished her as the mother of love; from φιλειν, *to love.*

PHILADELPHIA, in *Antiquity*, were games instituted at Sardis to celebrate the union of Caracalla and Geta, the sons of Septimius Severus.

PHILADELPHIA, the second city in size and importance in the United States of North America, and the commercial metropolis of Pennsylvania. It is situated on the west bank of the Delaware, five miles from its junction with the Schuylkill, and extending from the one river to the other. From the city to the estuary of the Delaware, the distance is a hundred and twenty-six miles, including the bendings of the river; but the stream is so broad and deep at Philadelphia as to afford sufficient water for vessels of any size except those of the first class. Originally it formed a parallelogram, extending west about two miles from the Delaware, beyond the Schyulkill, and north and south a little more than a mile. As commerce increased, Philadelphia of course was enlarged, the buildings naturally extending along the Delaware, and now forms an oblong square reaching from the lower part of Southwark to the upper part of Kensington, nearly four miles, and, as we have said, from the one river to the other. It is noted for the regularity with which it is laid out. The main streets, twenty-five in number, and running from north to south, are intersected at right angles by others stretching east and west. There is an immense number of squares, it is supposed above three hundred and fifty. Some of the streets are a hundred feet and upwards in breadth; they are all well paved, and kept remarkably clean, being mostly furnished with common sewers. The houses altogether exhibit an appearance of neatness, uniformity, and commodiousness, and most of them are ornamented with white marble steps and window-sills. The most conspicuous buildings are some of the churches, the state-house, the United States and Pennsylvania banks, the institution for the deaf and dumb, and the Pennsylvania hospital. There are above a hundred places of public worship, but, with the exception of the first Presbyterian church, and two or three Episcopalian chapels, which are noble edifices, they are neither remarkable for their architecture nor their size. The front of Pennsylvania hospital is two hundred and seventy-three feet in breadth; and in connection with it there is a building sufficiently large to contain above fifty patients. There are a number of other institutions for the sick and the destitute, the buildings of which, together with the former, occupy an entire square, in the centre of which is a leaden statue of the founder of the city. The building for the reception of the deaf and dumb was erected in 1824, and is constructed of granite. It is of considerable size, and, having received handsome dona-

Philadelphia.

tions from various quarters, the managers of the institution are enabled to receive pupils from other states besides that in which it is situated. The object of this school is to give a common education to the deaf and dumb, and to train them to industrious habits, the course of instruction varying from four to six years.

The bank of the United States was established in the year 1816, with a capital of thirty-five millions of dollars. The banking-house is a splendid structure, built on the plan of the Parthenon at Athens, and is considered as the most finished specimen of pure Grecian architecture in America. It is constructed of white marble, having in front eight fluted Doric columns, four feet and a half in diameter. On each of the fronts is a portico projecting ten feet and a half. The whole length of the edifice, including the portico, is a hundred and sixty-one feet; its breadth being eighty-seven feet. The banking-room, which occupies the centre of the building, is eighty-one feet in length by forty-eight feet in breadth. The whole immense structure is arched, and rendered bomb-proof from the cellar to the roof, which is covered with copper. The bank of Pennsylvania is likewise a fine specimen of classical architecture, and built of the same material as the former. The state-house is a large brick building, comprising a centre and two wings, and presenting altogether a venerable appearance, never having been altered since its first erection. In the eyes of the Americans it will remain a feature of great interest as long as it lasts; for it was here the continental congress held its meetings, and from it the declaration of independence was first promulgated. There are several theatres, which are esteemed highly respectable buildings. The masonic hall, built in the Gothic style, is a large edifice, but more remarkable for its size than for its architectural beauty. The arcade is an imposing stone structure, containing the best museum in America; and the academy of arts is likewise a respectable edifice, enriched internally with a large number of paintings and some very fine statues. The university of Pennsylvania is distinguished by the celebrity of the medical school attached to it. The new halls, which were erected in the year 1830, are spacious, and built in a handsome style of architecture. The number of medical students who attend it vary from 400 to 500 annually. The hall of the Jefferson medical college is also a spacious building. There are three prisons in Philadelphia, one of which is built in the style of the castles of the middle ages, and is considered as a great ornament to the city. It is called the New Penitentiary, and occupies ten acres of ground, being designed to carry the principle of solitary confinement completely into effect.

The United States mint was established in Philadelphia in the year 1791, and by several successive acts of congress has been continued in the same place ever since. The old buildings, however, have been supplanted by a spacious new edifice, which was commenced in 1829. This splendid structure is faced with marble, and presents a front of a hundred and twenty-two feet, divided into a portico sixty-two feet long, and two wings each of thirty feet in length. The building is of the Ionic order, taken from the celebrated Grecian temple on the river Illisus, near Athens. The total value of the gold, silver, and copper coinage struck at this mint during the year ending January 1837 was 7,764,900 dollars. The report for that year states that great and important improvements had been introduced into every department of the mint. Changes have been made in the arrangements for assaying, which place this part of the establishment upon a footing with the most perfect in Europe. The marine asylum stands on the eastern bank of the Schuylkill, a short distance south of the city line. It is three hundred and eighty-six feet in length, consisting of a portico of ninety feet, supported by eight Ionic columns, and two wings, each a hundred and forty-eight feet in extent. But of all the public works of Philadelphia there are none of which its inhabitants are so justly proud as those at Fair Mount, by which the city is supplied with water of the best quality, and in the greatest abundance. Nothing of the kind has been executed on the American side of the Atlantic that will bear any comparison with the arduous and expensive operation of introducing the Schuylkill water. At two different times plans were adopted for the purpose of supplying Philadelphia with water; but both having proved inefficient, the present magnificent undertaking was commenced in 1819, and completed at an expense of about one million and a half of dollars. Fair Mount is in the rear of the city, upon the bank of the Schuylkill, the neighbourhood of which presents some remarkably beautiful and romantic scenery. The reservoirs are situated on the top of a hill rising from the river, a part of it perpendicular rock, to the height of a hundred feet. They are calculated to contain thirty millions of gallons of water, which is sufficient to supply the city for ten days. It was formerly forced into the reservoirs by means of steam, which is no longer used; it is now raised by machinery propelled by the river. There are five large water-wheels turned, one of which, made of iron, weighs twenty-four tons. If all are put in motion at once, they will raise seven millions of gallons in twenty-four hours, which is more than double the quantity required even in summer. To turn them, the Schuylkill has been dammed in its whole breadth, by which the water is thrown back into a reservoir lock, whence it is admitted as required to operate upon the wheels, and is discharged into the river below the dam. The iron pipes through which the water is conveyed to the city and districts are about sixty miles in extent. The water thus circulated so abundantly through the city is of immense service in cases of fire, as it is only necessary to screw the hose to hydrants, which are placed at convenient distances, to secure a constant stream of sufficient force to reach any ordinary height. There are sixteen hose companies, and about thirty engine companies; in short, the arrangements made in Philadelphia for the speedy extinction of conflagrations are of the first order.

The city library is indebted for its origin to Benjamin Franklin. It was commenced as early as 1731, and incorporated eleven years afterwards. In 1790 the present neat and ornamental edifice was erected opposite to the state-house square; and over the front door is placed a fine marble statue of its founder. In 1837 it contained 44,000 volumes. There are other institutions of the kind, which contain upwards of ten thousand volumes. Opposite the Philadelphia library is the Athenæum, a valuable institution, established in 1814. Attached to it is a library, and a spacious reading-room, well supplied with newspapers from Europe and other quarters of the world, besides nearly a hundred from various parts of the United States. The university of Philadelphia was founded in the year 1755, and is one of the most respectable and flourishing institutions of the kind in the union. Academies and other seminaries of education are numerous, and efficiently conducted. The city and county of Philadelphia constitute a school district, under special regulations. By the report for the year 1837, it appears that the schools in it were attended by above eleven thousand children; and from the same document we learn that the arrangements for the general diffusion of instruction are very extensive and highly efficient. There are in this city a number of benevolent societies, various institutions which have for their object the relief of the sick, the helpless, the destitute, and other objects of compassion. In this respect it is upon a level with any city of the same size in Europe.

The harbour of Philadelphia, from the peculiar nature of the Delaware River, is more liable to be impeded by ice

Philadelphia. than those of New York and Baltimore; but otherwise it possesses perhaps as many natural advantages as either of them. Its trade is very great, as will be seen in the article Pennsylvania. The navy-yard situated on the Delaware is of great extent, and fitted up with first-rate appurtenances for building frigates and ships of the line. Shipbuilding is briskly carried on; and this city has also a high reputation for the extent and excellence of its breweries. It is, besides, famous for its manufactures, paper-making, printing, and publishing establishments, and its periodicals and journals of every description.

Philadelphia was founded by William Penn in the year 1682. On the 5th of September 1774 the members of the first congress assembled here, and adopted that celebrated declaration of rights, the preface to the declaration of independence which was promulgated from the state-house about two years afterwards. Congress continued to sit in this city until the approach of the royalists in September 1777, when it fell into their hands, and was retained by them until June following. During the remainder of the war it happily escaped the ravages of hostile operations. It was also the seat of the state government until the year 1800. For municipal purposes the legislature has from time to time established corporate governments in different parts of the suburbs, so that Philadelphia is now divided into several districts. The municipal government of the city proper is vested in a mayor, a recorder, fifteen aldermen, and a select and common council, besides subordinate executive officers. The recorder and aldermen are appointed by the governor of the state; and the mayor is chosen by the councils, from the body of the citizens. The members of the select and common council are annually elected by the people. They receive no compensation, sit in separate chambers, and each body has a negative on the legislative acts of the other. The city proper sends seven representatives and two senators to the state legislature. The population of Philadelphia, according to the census of 1810, was 96,664, in 1820 it was 119,325, in 1830 it was 167,811, and at present (1838) it is estimated at about 200,000 souls.

Philadelphia, the name of an ancient town of Turkey, in Asia Minor, or Natolia, founded by Attalus Philadelphus, brother of Eumenes. In the year 1097 it was taken by John Ducas, the Greek general; and, in the year 1106, it was, without difficulty, reduced by the same individual. The Turks marched from the East with a design to plunder this and the maritime towns; and, in 1175, the Emperor Manuel retired thither for protection against these invaders. In 1300, it fell by lot to Karaman. In 1306, it was besieged by Alifaras, and considerably harassed, but not taken. In 1391, Philadelphia alone refused to admit Bajazet; but it was at length forced to capitulate, from want of provisions. It has been matter of surprise that this town was not totally abandoned; and yet it has survived many cities less liable to inconveniences, and is still an extensive place, though in its appearance it is poor and mean. Some remnants of its walls are still standing.

Philadelphian *Society*, in *Ecclesiastical History*, was an obscure and inconsiderable society of mystics. They were formed about the end of the seventeenth century by an English female fanatic, whose name was Jane Leadley. This woman seduced, by her visions, predictions, and doctrines, several disciples, amongst whom were some persons of learning. She believed that all dissensions amongst Christians would cease, and that the kingdom of the Redeemer would become a scene of charity and felicity, if Christians, disregarding the forms of doctrine or discipline in their several communions, would all join in committing their souls to the care of the internal guide, to be instructed, governed, and formed by his divine impulse and suggestions. She even went farther than this, pretending a divine commission to proclaim the approach of the communion of saints; and declaring that the society established by herself was the true kingdom of Christ. One of her leading doctrines was that of the final restoration of all intelligent beings to perfection and happiness.

PHILADELPHUS, in *Antiquity*, was a title or surname borne by several ancient kings, being formed from the Greek φιλος, *friend*, and ἀδελφος, *brother*; that is, one who loves his brother or brethren.

PHILÆNI, were two brothers, citizens of Carthage, who sacrificed their lives for the benefit of their country. At the time when the Carthaginians ruled over the greater part of Africa, the Cyrenians were also a great and wealthy people. The intervening country being all sandy, and of an uniform appearance, there was neither river nor mountain to distinguish their limits; a circumstance which involved them in frequent disputes and contentions. After their armies and fleets had often been routed and put to flight on both sides, and they had weakened one another greatly, fearing lest, by and by, some third people should fall upon the conquered and the conquerors, both parties agreed to a cessation of arms, which was followed by an engagement, "that upon a day appointed deputies should set out from their respective homes, and the place where they met one another should be accounted the common boundary of both nations." Accordingly, the two brothers called Philæni, when sent from Carthage, made all despatch to perform their journey. The Cyrenians, who proceeded more slowly, found themselves somewhat late; and becoming apprehensive of punishment for mismanaging the affair, charged the Carthaginians with setting out before the appointed time, and made a mighty bustle about it, being resolved not to be overreached. But as the Carthaginians declared their willingness to accept any other terms, provided only these were fair, the Cyrenians made this proposal to the Carthaginians, viz. either to be buried alive in the place which they claimed as the boundary to their nation, or to advance forward to whatever place they inclined upon the same condition. The Philæni accepted the offer, and, sacrificing themselves to their country, were actually buried alive. In the spot where they were interred the Carthaginians dedicated to the memory of the two brothers altars, which, being called *Aræ Philænorum*, served as a boundary to the empire of the Carthaginians, which now extended from this monument to the Pillars of Hercules, or, according to the observations of the moderns, about 1420 geographical miles. Sallust, in his history of the Jugurthan war, records the singular circumstance here related.

PHILANTHROPY is compounded of two Greek words signifying the love of mankind. It is therefore of nearly the same import with *benevolence*, and differs from *friendship*, as the latter affection subsists only between a few individuals, whereas philanthropy comprehends the whole human race.

Whether man has an instinctive propensity to love his species, which makes him incapable of happiness except in the midst of society, and impels him to do all the good that he can to others, feeling their felicity an addition to his own, is a question which has been warmly debated amongst philosophers ever since metaphysics was studied as a science. See Metaphysics and Moral Philosophy.

PHILEMON, a writer of the new comedy, was born at Soli, in Cilicia, but the precise date of his birth and death is unknown. He began to exhibit his plays at Athens in the reign of Alexander, B. C. 336–323, and died in the reign of the second Antigonus, son of Demetrius, probably about B. C. 280, at the age of ninety-six. He was the contemporary of Menander, and frequently carried off the prize from him, by the attention he paid to humour the prejudices of the people. He was the author of ninety comedies, the names of fifty-one of which are given by Fabricius in his *Bibliotheca Græca*, having been collected from Athenæus, Pollux, and other ancient authors. Plautus imitated Philemon in his comedy of the Merchant, and in that of the Bacchides. The fragments of Philemon have been collected by Hertel and Gronovius. They have also been published along with the fragments of Menander, Amsterdam, 1709, 8vo. (See MENANDER.)

PHILETAS, a Greek poet and grammarian, belonging to the island of Cos, flourished under Philip and Alexander the Great, and was preceptor of Ptolemy Philadelphus. He was the author of some Elegies, Epigrams, and other works, which have not come down to us, and is celebrated in the poems of Ovid and Propertius as one of the best poets of his age. Ælian informs us, we presume in jest, that his body was so slender and feeble, that he was obliged to have some lead in his pockets, to prevent his being carried away by the wind.

PHILIBEG, called also a *kilt*, is a sort of short petticoat reaching nearly to the knees, which is worn by the Scotch Highlanders. It is a modern substitute for the lower part of the plaid, being found to be less cumbersome, especially in time of action, when the Highlanders used to tuck the brechtan into their girdle.

PHILIP, one of the apostles, was a native of Bethsaida in Galilee. Jesus Christ having seen him, said to him, "Follow me." Philip obeyed, and soon afterwards finding Nathaniel, said to him, "We have found the Messiah, of whom Moses and the prophets have spoken, Jesus of Nazareth, the son of Joseph." Nathaniel, however, true to the prejudices of his time, asked him, "Can any thing good come out of Nazareth?" To this Philip replied, "Come and see." He then brought Nathaniel to Jesus, and they went with him to the marriage at Cana in Galilee. Philip was called at the very beginning of our Saviour's mission; and when Jesus Christ was about to feed the five thousand who followed him to the wilderness, he asked Philip, in order to prove him, whence bread might be bought for such a multitude of people? Philip answered, that two hundred pennyworth of bread would not be sufficient for every one to taste a little. Some Gentiles, having a curiosity to see Jesus Christ, a little before his passion, addressed themselves to Philip, who mentioned it to Andrew, and both of them to Christ. At the last supper, Philip besought our Saviour that he would be pleased to show them the Father, being all that they desired. But Jesus told them, that, seeing the Son, they saw the Father also. This is all we learn in the gospel concerning Philip.

Upper Asia fell to the lot of this apostle, who took great pains in planting the gospel there, and by his preaching and miracles made many converts. In the latter part of his life he went to Hierapolis in Phrygia, a city much addicted to idolatry, and particularly to the worship of a serpent of a prodigious size. Philip, by his prayers, procured the death, or at least the disappearance, of this monster, and convinced its worshippers of the absurdity of paying divine honours to such odious creatures. But the magistrates, enraged at his success, imprisoned him, and ordered him to be severely scourged, and then put to death, which some say was done by crucifixion, and others by hanging him up against a pillar. Philip is generally reckoned amongst the married apostles; and it is said he had three daughters, two of whom preserved their virginity, and died at Hierapolis, whilst the third, having led a very spiritual life, died at Ephesus. He left no writings behind him, the gospel under his name having been forged by the Gnostics, to countenance their evil principles and worse practices. The Christian church observes the festival of this saint, together with that of St James, on the first day of May.

PHILIP, the name of several kings of Macedonia, the most celebrated of whom was Philip II., father of Alexander the Great. See GREECE and MACEDONIA.

PHILIP. Both France and Spain have likewise had several sovereigns distinguished by this name. See FRANCE and SPAIN.

PHILIP II. son of the Emperor Charles V. and of Isabella of Portugal, was born at Valladolid on the 21st of May 1527, and became king of Naples and Sicily on his father's abdication in 1554. The reign of this prince touches the contemporary history of Europe at so many important points, that a brief notice of it will not perhaps be thought superfluous. He ascended the throne of Spain on the 17th of January 1556. Charles had made a truce with the French, but his son broke it, and having formed an alliance with England, poured into Picardy an army of forty thousand men. The French were cut to pieces at the battle of St Quintin, which was fought on the 20th of August 1557; that town was taken by assault, and the day on which the breach was stormed, Philip appeared armed cap-à-pied, in order to animate the soldiers. It was the first and last time that he was observed to wear the military dress. It is well known, indeed, that during the heat of the action his terror was so great that he made two vows; one, that he should never again be present in a battle; and the other, that he would build a magnificent monastery, dedicated to St Lawrence, to whom he attributed the success of his arms. After the engagement, the Duke of Savoy, who commanded, attempted to kiss his hand; but Philip prevented him, saying, "It is rather my duty to kiss yours, who have the merit of so glorious a victory;" and immediately presented him with the colours taken during the action. The taking of Catelet, Ham, and Noyon, were the only advantages derived from a victory which might have proved the ruin of France. When Charles V. was informed of this success, it is said he asked the person who brought him the intelligence, if his son was at Paris; and being answered in the negative, he went away without uttering a single word. The Duke of Guise having had time to assemble an army, repaired the disgrace of his country by the taking of Calais and Thionville. But whilst the duke was animating the French, Philip defeated Marshal de Thermes in a combat near Gravelines. His army was, on this occasion, commanded by Count Egmont, whom he afterwards caused to be beheaded. The conqueror made no better use of the victory of Gravelines than he had done of that of St Quintin; but he reaped considerable advantage from the glorious peace of Chateau-Cambresis, the masterpiece of his politics. By that treaty, which was concluded on the 13th of April 1559, he gained possession of the strong places of Thionville, Marienbourg, Montmedi, Hesdin, and the county of Charollois. This war, so terrible in itself, and attended with so much cruelty, was, like many others, terminated by a marriage. Philip took for his third wife Elizabeth, daughter of Henry II. who had been promised to his son Don Carlos.

After these glorious achievements, Philip returned in triumph to Spain without having drawn a sword. His first care, upon his arrival at Valladolid, was to demand of the grand inquisitor the spectacle of an *auto-da-fé*. This was immediately granted him, and forty wretches, some of them priests and monks, were strangled and burned. Don Carlos de Seza, one of these unfortunate victims, ventured to draw near to the king, and said to him, "How, Sir, can you suffer so many wretches to be committed to the flames? Can you be witness of such barbarity without weeping?" To this Philip coolly replied, "If my own son were suspected of heresy, I would myself give him up to the severity of the Inquisition. Such is the horror which I feel when I think of you and your companions, that if an executioner were wanting, I would myself supply his place." On other occasions he conducted himself agreeably to the spirit which had dictated this answer.

Philip.

In a valley of Piedmont, bordering on the country of the Milanese, there were some heretics, the followers of Peter Valdo; and these the governor of Milan was commanded to put to death by the gibbet. The new opinions having found their way into some of the districts of Calabria; Philip gave orders that the innovators should be put to the sword.

This spirit of cruelty, and shameful abuse of power, had the effect of weakening that power itself. The Flemings, no longer able to endure so hard a yoke, revolted. The revolution began in the fine and large provinces of the Continent; but the maritime provinces alone obtained their liberty. In 1579 they formed themselves into a republic, under the title of the United Provinces. Philip sent the Duke of Alva to reduce them; but the cruelty of that general only served to exasperate the spirit of the rebels. Never did men fight with more courage or greater fury. The Spaniards, at the siege of Haerlem, having thrown into the town the head of a Dutch officer who had been killed in a skirmish, the inhabitants threw back to them the heads of eleven Spaniards, with this inscription: "Ten heads for the payment of the tenth penny, and the eleventh for interest." Haerlem having surrendered at discretion, the conquerors caused all the magistrates, pastors, and above 1500 citizens, to be hanged.

The Duke of Alva being at length recalled, the grand commander of the Requesnes was sent in his place, and after his death Don John of Austria; but neither of these generals could restore tranquillity in the Low Countries. To the latter succeeded a grandson of Charles V., Alexander Farnese, duke of Parma, the greatest commander of his time; but he could neither prevent the independence of the United Provinces, nor check the advancement of that republic which arose under his very eye. It was then that Philip, always at his ease in Spain, instead of coming to reduce the rebels in Flanders, proscribed the Prince of Orange, and set 25,000 crowns upon his head. But William, superior to Philip, disdained having recourse to any similar proceeding, and trusted to his sword for his preservation. In the mean time the king of Spain succeeded to the crown of Portugal, to which he had a right by his mother Isabella. This kingdom had been subdued by the Duke of Alva in the space of three weeks, during the year 1580. Antony, prior of Crato, having been proclaimed king by the populace of Lisbon, had the resolution to come to an engagement; but he was vanquished, pursued, and obliged to fly for his life.

A cowardly assassin, Balthazar Gerard, killed the Prince of Orange by a pistol-shot, and thereby delivered Philip from his most implacable enemy. Philip was charged with this crime, but it is believed without reason; although, when the tidings were communicated to him, he was imprudent enough to exclaim, "If this blow had been given two years ago, the Catholic religion and I would have gained a great deal by it." This murder had not the effect of restoring to Philip the Seven United Provinces; and that republic, already powerful by sea, assisted England against him. In the year 1588, Philip, having resolved to distress Elizabeth, fitted out a fleet called the Invincible Armada. It consisted of 150 large ships, on board of which were mounted 2650 pieces of cannon, 8000 seamen, 20,000 soldiers, and the flower of the Spanish nobility. This fleet, commanded by the Duke of Medina Sidonia, sailed from Lisbon when the season was too far advanced; and, being overtaken by a violent storm, a great part of it was dispersed. Twelve ships, driven upon the coast of England, were captured by the English fleet, which consisted of 100 sail; fifty were wrecked upon the coasts of France, Scotland, Ireland, Holland, and Denmark. Such was the disastrous fate of an expedition, from which nothing less than the subjugation of England had been anticipated.

This enterprise, which cost Spain forty millions of ducats, 20,000 men, and 100 ships, was productive only of disgrace. But Philip supported his misfortune with heroic resolution. When one of his courtiers told him, with an air of consternation, what had happened, he coolly replied, "I sent to fight the English, and not the winds. God's will be done." The day after, Philip ordered the bishops to return thanks to God for having preserved some remains of his fleet; and he wrote thus to the pope: "Holy father, as long as I remain master of the fountain-head, I shall not much regard the loss of a rivulet. I will thank the Supreme Disposer of empires, who has given me the power of easily repairing a disaster which my enemies must attribute solely to the elements, that have fought for them."

At the same time that Philip openly attacked England, he was secretly encouraging the league in France, the object of which was to overturn the throne and divide the state. The leaguers conferred upon him the title of protector of their association, which he eagerly accepted, from a persuasion that their exertions would soon conduct him, or one of his family, to the throne of France. So sure did he think himself of his prey, that when speaking of the principal cities in France, he used to say, "my fine city of Paris, my fine city of Orleans," in the same manner as he would have spoken of Madrid or Seville. What was the result of all these intrigues? Henry IV. embraced the Catholic religion, and by his abjuration of Protestantism annihilated the hopes of his rival.

At length Philip, worn out by the debaucheries of his youth, and by the toils of government, drew near to his last hour. But a slow fever, the most painful gout, and a complication of other disorders, could not disengage him from business, or draw from him the least complaint. "What," said he to the physician, who hesitated about letting blood of him, "are you afraid of drawing a few drops of blood from the veins of a king who has made whole rivers of it flow from heretics?" At last, exhausted by a complication of disorders, which he bore with heroic patience, he expired on the 13th of September 1589, aged seventy-two years, after a reign of forty-three years and eight months. During the last fifty days of his illness he showed a deep sense of religion, and had his eyes almost constantly turned towards heaven.

No character was ever drawn by different historians in more opposite colours than that of Philip; and yet, considering the length and activity of his reign, there is none which it should seem more easy to ascertain. From the facts recorded in history, we cannot doubt that he possessed, in an eminent degree, penetration, vigilance, and a capacity for government. His attention was continually directed towards every part of his extensive dominions. He entered into every branch of administration; watched over the conduct of his ministers with unwearied attention; and in his choice both of them and of his generals discovered a considerable share of sagacity. He had at all times a composed and settled countenance, and never appeared to be either elated or depressed. His temper was the most imperious, and his looks and demeanour were haughty and severe; yet amongst his Spanish subjects he was of easy access, listened patiently to their representations and complaints, and, where his ambition and bigotry did not interfere, was generally willing to redress their grievances. But when we have said this much in his praise, we have said all that truth requires or truth permits. It is indeed impossible to suppose that he was insincere in his zeal for religion. But as his religion was of the most corrupt kind, it served to increase the natural depravity of his disposition; and not only allowed, but even prompted him to commit the most odious and shocking crimes. Although a prince in the bigoted age of Philip might be persuaded that the interest of religion would be advanced by falsehood and persecution, yet it might have been expected that, in a virtuous prince, the sentiments of honour and humanity would on some occasions triumph over the dictates of superstition. But of this triumph there occurs not a single instance in the reign of Philip, who, without hesitation, violated his most sacred obligations as often as religion afforded him a pretence for doing so; and, under that cloak, he exercised for many years the most unrelenting cruelty without reluctance or remorse. His ambition which was exorbitant, his resentment which was implacable, his arbitrary temper which would submit to no control, concurred with his bigoted zeal for the Catholic religion, and carried the sanguinary spirit which that religion was supposed to inspire, to a greater height in Philip than it had ever attained in any other prince of that or of any previous or succeeding age.

Although of diminutive size, he had an agreeable person. His countenance was grave, his air tranquil, and one could not discover from his looks either joy in prosperity or chagrin in adversity. The wars against Holland, France, and England, cost Philip 564 millions of ducats; but America furnished him with more than the half of that sum. His revenues, after the junction of Portugal, are said to have amounted to twenty-five millions of ducats, of which he only laid out 100,000 for the support of his own household. Philip was very jealous of outward respect; and he was unwilling that any person should speak to him except kneeling. The Duke of Alva having one day entered his cabinet without being introduced, the king, with a stormy countenance, exclaimed, "An impudence like this of yours would deserve the hatchet." If he thought only how to make himself be feared, he succeeded in doing so; for few princes have been more dreaded, more abhorred, or have caused more blood to flow, than Philip II. of Spain. He had successively, if not all at once, to maintain war against Turkey, France, England, Holland, and almost all the Protestant states of the empire, without having a single ally, not even the branch of his own house in Germany. But, notwithstanding so many millions employed against the enemies of Spain, Philip found in his economy resources wherewith to build thirty citadels, sixty-four fortified places, nine seaports, twenty-five arsenals, and as many palaces, without including that of the Escorial. His debts amounted to 140 millions of ducats, of which, after having paid seven millions of interest, the greater part was due to the Genoese. Moreover, he had sold or alienated a capital stock of 100 millions of ducats in Italy. He made a law, fixing the majority of the kings of Spain at fourteen years of age. He affected to be more than commonly devout; he ate often at the refectory with the monks; he never entered the churches without kissing all the relics they contained; he caused his bread to be kneaded with the water of a fountain which was thought to possess a miraculous virtue; he boasted of never having danced, and of never wearing breeches after the Grecian fashion. Grave and solemn in all his actions, he drove from his presence a lady who had incautiously smiled whilst he was blowing his nose. One great event of his domestic life is the death of his son Don Carlos. The manner of this prince's death is not certainly known. His body, which is interred in the Escorial, built by Philip in execution of his vow on the field of battle, is there separated from his head; but it is pretended that the head is separated only because the leaden coffin which contains the body proved too small. The particulars of his crime are as little known as the manner in which it was committed. There is no evidence, nor is there any probability, that Philip had caused him to be condemned by the Inquisition. All that we know of the matter is, that in 1568 his father, having discovered that he had some correspondence with the Hollanders, arrested him in his own room, and had him placed in confinement. At the same time he wrote to Pope Pius V. giving him an account of his son's imprisonment; and in his letter to the sovereign pontiff, dated the 20th of January 1568, he says, "that from his earliest years the strength of a wicked nature has stifled in Don Carlos every paternal instruction." It was Philip II. who caused to be printed at Antwerp, between 1569 and 1572, in eight vols. folio, the fine Polyglot Bible which bears his name; and it was also he who subjected the islands afterwards called the *Philippines.*

Philip *Island* is an uncultivated but fruitful island, abounding in herbage, in the South Pacific Ocean, situated about six miles to the south of Norfolk Island. That it might be rendered as useful as possible to the British settlements on the shores of New Holland, the governor turned loose some hogs on it, in the hopes that they would multiply; and also sent some cows, with several settlers to take care of them. Owing, however, to the difficulty of approaching this island, from the tempestuous seas which constantly rage around its shores, it was at length wholly abandoned. This is also the name of a small island on the east coast of New Holland, which shelters Western Port. Long. 145. 25. E. Lat. 38. 33. S.

Philip *Islands*, two islands in the South Pacific Ocean, discovered in 1791, by Captain Hunter. They are joined together by a long sandy isthmus above water; and a sandbank extends from the largest island above half a mile into the sea. They are very dangerous to ships in the night. Long. 140. 3. E. Lat. 8. 6. S. This is also the name of an island in the South Pacific Ocean, discovered by Captain Turnbull. Long. 143. 57. W. Lat. 16. 24. S.

Philip *Port*, an inlet on the southern coast of New Holland, which extends about thirty miles into the land in a northerly direction. Long. of Point Nepean, the eastern point of the entrance, 144. 38. E. Lat. 38. 18. S.

PHILIPPI, a town of European Turkey, in Macedonia, at the foot of Mount Pangæus, eight miles from the seashore, and twenty-six leagues to the eastward of Salonica. On the plain near it was decided the fate of Rome in the battle fought by Augustus and Marc Antony on the one side, against Brutus and Cassius on the other. The place still exhibits the remains of an amphitheatre, and several other monuments of its antiquity and prosperity, although at present it has an inconsiderable population.

PHILIPPICS, Φιλιππικοι λογοι, in literature, is a name applied to the orations of Demosthenes against Philip king of Macedonia. The Philippics are reckoned the masterpieces of that great orator. This name is likewise applied to the fourteen orations of Cicero against Marc Antony.

PHILIPPINES. This archipelago, in the Eastern Seas, extends from the fifth to the twentieth degree of north latitude, and consists of a great number of islands of various sizes, and many of which are but little known. The largest of the group is Luzon or Luconia; and to the south lie the other principal islands, namely, Mindoro, Panay, Marindique, Negros, Masbate, Zebu, Bohol, Leyte, Samar, and Magindanao. There are, besides, several smaller ones, and they are all, nominally at least, subordinate to the Spanish government at Manilla; but its power does not extend over all parts of the islands. There are many remote places to which the Spaniards have never been able to penetrate. Amongst their fastnesses and mountains, the natives roam in a state of barbarous independence, and wage an inveterate war against their Spanish oppressors. These islands, which are partially colonized, pay tribute, which is collected by the Spanish magistrates in the provinces or districts into which the country is subdivided. The appellation of Philippines was given to them in compliment to Philip II. of Spain, who at the time of their subjugation was prince of the Asturias.

The Philippines, from their situation, possess a tropical climate, and are subject to the periodical rains, though the heats are moderated by the breeze from the sea. The rains generally commence in May, and last till September, but sometimes they are protracted to the beginning of December; from which latter period till the succeeding May the weather is delightful, being a perpetual spring. The vegetation is luxuriant, owing to the copious rains; the trees are constantly covered with leaves, and the soil with verdure, so that it is difficult to keep the land clear of weeds and insects. The winds which most commonly prevail are the north, the east, and the south-west, each of which continues for four months; the change of wind being attended with violent storms of thunder and lightning, and at times by whirlwinds. These storms rage occasionally with frightful violence, and blow from every point of the compass in the course of twenty-four hours, ravaging and destroying the country, and tearing up trees by the roots.

These islands, from their extent, their climate, and the fertility of their soil, would produce all sorts of colonial products, if there were adequate industry on the part of the inhabitants. Their chief production, however, is rice, which is the principal subsistence of the natives. They cultivate, besides the bread-fruit, beans, the cacavata, &c.; and the palm-tree is much attended to, as it yields a spirit and an oil, besides a sweetmeat named chanaca. The pith of the palm, the young shoots of the sugar-cane, green withes, and other succulents, serve as substitutes for rice to those who cannot procure anything better. The other products are different sorts of pulse, such as mangos, patani, kidney beans, and millet. They have not many fruit-trees, and they are, besides, of an indifferent quality, excepting the plantain, to which may be added the orange and the mango. The areca or betel-nut is also cultivated, and used in great quantities, both by Spaniards and by natives. The domestic animals are buffaloes, goats, pigs, ducks, and fowls. Horses and horned cattle, having been imported in great numbers by the Spaniards, have multiplied to such a degree that they now run wild in the mountains, without being claimed by any owner. Deer abound in the mountains, and all sorts of pigeons swarm in the fields, with other small birds, such as quails, a species of partridge, woodcocks, &c. The swallow which builds the edible bird-nests so much esteemed by the Chinese is found here. The surrounding seas yield abundant supplies of fish, which afford a wholesome nourishment to the inhabitants. The natives take a great delight in fishing, as it flatters their natural indolence, and gives them a supply of fish, which they prefer to flesh. Shells in great variety are found upon the shores; amongst these are the cowries, and the enormous kima cockle, so large as to hold a gallon, and used in the churches as vessels for containing holy water. They have also introduced sheep, as well as geese; and amongst vegetables, grapes, figs, wheat, pepper, cocoa, coffee, sugar, tobacco, and various sorts of plants, which have thriven remarkably well.

These islands contain many valuable mineral productions. In the interior there are mines of gold and of iron, but they are not worked, either from a deficiency of produce, or from the want of skill and industry amongst the inhabitants. Gold is also procured by washing the sand which is found in the mountain streams. At one place the gold mines are so indolently worked as scarcely to defray the expense. The mountains abound in excellent timber, both for ship and house building; and the bamboos are large and long. Some of them are of the thickness of a man's thigh; and of these the native houses are constructed, after which they are covered with palm-leaves. The inhabitants also raise a little cotton for clothing, which is dyed with indigo, logwood, &c. The other productions of the Philippines which are articles of export, consist of wax, wild honey, amber, marble, tar, brimstone, and other lesser articles.

These islands, notwithstanding their natural fertility, continue in a very desolate state, which is owing partly to physical disadvantages, namely, the hurricanes, which sweep across the country with wide-wasting desolation, and to the destruction caused by rats, insects, and other vermin, which swarm in all parts, and are a great annoyance; partly also to the indolence of the natives, and to the intolerant and illiberal policy of the Spaniards. If the Chinese were encouraged by an enlightened government, they would settle in great numbers in these islands, and by their enterprise and industry would soon change the face of the country. These islands import a variety of piece-goods, especially ordinary long cloth, white, blue, and red; handkerchiefs of all kinds; chintz, principally dark grounds; Surat goods of most sorts, and all kinds of European cutlery and iron. The exports are the edible bird-nests, cassia, gold-dust, pepper, rattans, sago, tortoise-shell, wax, wild honey, amber, marble, tar, brimstone, and other articles of inferior note. The native Indians trade with each other for the different productions of their country, and employ gold as the medium of exchange. They likewise carry on a trade, though inconsiderable, with the Chinese and the Malays of Borneo, for flag-stones, copper, and articles of furniture. They are rude in their manners, and go about almost naked. These islands are visited by junks which come from several parts of the Chinese empire, bringing various articles for the consumption of the numerous resident Chinese, and silk-goods, lackered ware, china-ware, and teas, for the Acapulco ships. Cochineal, black wood, and dollars, constitute the returns. A trade is also carried on with the British settlements, though not to any great extent.

The Spaniards who first visited these islands spread the most extraordinary and incredible tales of their inhabitants, whom they described as divided into three classes, satyrs, men with tails, and sea-monsters. There were only in these islands two races, the Bisayan Indians, and that strange race of oriental negroes who still occupy the Papuan Isles. The latter roamed the mountains almost in a state of nature, merely covering the fore-part of the body with the bark of a tree, and living on roots, or on such animals as they could kill with their bows and arrows, and the flesh of which they devoured raw. In short, they were nearly on a level in their habits and manners with the beasts of the forest. The Spaniards have succeeded in domesticating them, and introducing amongst them an imperfect civilization. But their barbarous aversion to labour they have never been able to conquer. They are of opinion that the negroes were the indigenous inhabitants of the islands, and that the Bisayans were intruders. At present the Papuans are few in number, and consequently feeble; yet they retain all their original hatred to the Bisayans, whom they lie in wait for and murder without remorse. There are, besides, several other races who inhabit the Philippines, and differ in features, language, and manners. The Pampangos reside to the north of Manilla, as also the painted races termed by the Spaniards Pintados, from whom these islands were originally named Islas de Pintados. The Indians found by the Spaniards in these islands were of regular stature, and an olive complexion, with flat noses, large eyes, and long hair. They were all governed by their chiefs, and their different villages waged an everlasting war with each other. The prisoners on each side were condemned to slavery. In some places a race of Indians was discovered whiter than the others, the descendants, as is supposed, of Chinese who had been wrecked on the coasts, and who had intermarried with Indians. The tribes of Igorrates or Ilocas, in particular, have eyes resembling the Chinese. Their customs and usages mark a barbarous people. They have no fixed laws. Certain traditions are the only rules which they have for deciding civil suits; and criminal cases are generally compounded for a sum of money, unless in cases of murder, where one tribe retaliates upon another, and a scene of bloody contention ensues. They are permitted to have only one wife. But the principal persons have several concubines, who are slaves. No great reformation of manners has been effected by the Spaniards, nor have they made any great progress in the conversion of the natives. The Tagala or Gala language is in general use throughout the Philippine Islands. The dialects are so many and various, that the inhabitants of one province are not intelligible in those of another; yet their language is all derived from one common stock. Their religion is a rude species of idolatry, and consists in frantic ceremonies and sacrifices to idols, of which the details would be of little interest.

These islands were discovered in 1521, by Magelhaens, who named them the Archipelago of St Lazarus. In 1565 they were taken possession of by a fleet which was despatched from Mexico, in consequence of orders from Philip II. of Spain, and first stopped at the island of Zebu, which was soon wholly subdued. In 1570 a fleet sailed from the island of Panay for Luzon, and, after several engagements with the princes of the country, effected a settlement at the mouth of the Manilla River. In 1571 the Spanish admiral took possession of the town of Manilla, which he constituted the capital of the Spanish possessions in the Philippines, and proceeded in his reduction of the island under the Spanish authority. In 1574 the existence of the Spanish settlement was threatened by a Chinese pirate, who arrived with sixty-two junks; but, after many bloody engagements, he was expelled, and great part of his army destroyed. Towards the conclusion of the sixteenth century a considerable trade was openly carried on with Japan; and many rich cargoes were brought from that country to Manilla, which had now become an emporium of the trade with China, Java, the coast of Coromandel, and Mexico. In 1590 the island of Sooloo was attacked by the Spaniards, but they were repulsed with great slaughter by the natives; nor could the Spanish maritime force make any impression on the Sooloo pirates, who have continued for nearly three centuries the scourge of these seas. The number of industrious Chinese had been daily increasing in the Philippines, and about the year 1639 they amounted to 30,000, most of whom were settled as cultivators. The Spaniards were always jealous of them, though they enriched the country by their industry; and that year, in consequence of suspected disaffection, they commenced a war against them, and made so dreadful a havoc amongst them, that in a short time their numbers were diminished to 7000, who surrendered at discretion. In 1757, the Chinese, who had again increased in the island, were all banished to their own country; and, to prevent their future establishment in the archipelago, the quarter of St Fernando was appropriated for the reception of such Chinese as should come to the island for the purposes of commerce, and regulations were made for their re-embarkation in good time, unless they should be in the mean time converted to the Christian religion, in which case they were permitted to settle as cultivators. In 1762, Manilla was attacked by a British fleet under Admiral Cornish and General Draper, and the place was stormed on the 5th of October. A capitulation was agreed upon next day, when, in order to redeem the city from general plunder, a ransom was agreed upon of four millions of dollars. Manilla was restored to the Spaniards at the peace of 1763, and has ever since remained in their possession. Besides Manilla and the larger establishments in Luzon, the Spaniards have many smaller settlements scattered over the islands to the southward; but such is the weakness of their government, that they have never been able to protect them against the attacks of the pirates who infest these seas. And so jealous of the natives are the Spanish rulers of these islands, that, though unable to defend them, they do not allow the natives to possess arms, or any sort of iron, which is a royal monopoly. In the year 1809 they published a declaration of their adherence to Ferdinand VII. and opened their ports to the British; and since that period a free trade has been carried on to a considerable extent. (F.)

PHILIPPISTS, a sect or party amongst the Lutherans, who followed Philip Melancthon. He had strenuously opposed the Ubiquists, who arose in his time; and the dispute growing still hotter after his death, the members of the university of Wirtemberg, who espoused Melancthon's opinion, were called by the Flacians, who attacked it, *Philippists.*

PHILIPPOPEL, a city of Turkey in Europe, in the government of Rumelia, and in the department of Sofla, the Turkish name of which is Filibé. It stands upon a plain, watered by the river Maritza, which is to a certain extent navigable, in a beautiful situation, on the great road from the frontiers to Constantinople. It is a well-built place, and has twenty mosques, two caravanserais, several Greek and Armenian churches, and many public and private baths. It is the seat of a Greek archbishop, and also a manufacturing city, in which woollen, silk, and cotton goods are made; and there are some very extensive tanneries. The commodities thus produced form a portion of the exports, to which are added raw materials, such as wool and silk. A great quantity of rice is grown on the banks of the river, and much tobacco, as well as abundance of grapes, on the more elevated parts. The inhabitants are stated to be about 30,000.

PHILIPS, Fabian, the author of several books relating to ancient customs and privileges in England, was born at Prestbury in Gloucestershire, on the 28th of September 1601. When very young, he spent some time in one of the Inns of Chancery, and went from thence to the Middle Temple, where he became learned in the law. In the civil wars, he was a bold assertor of the king's prerogative, and so strongly attached to Charles I. that, two days before that monarch was beheaded, he wrote a protestation against the intended murder, and caused it to be printed, and affixed to posts in all the public places. He likewise published, in 1649, a quarto pamphlet entitled *Veritas Inconcussa*, or King Charles I. no Man of Blood, but a Martyr for his People, which was reprinted in 1660, 8vo. In 1663, when the courts of justice at Westminster, especially the chancery, were dissolved by Cromwell's parliament, he published Considerations against the dissolving and taking them away, for which he received the thanks of parliament. He was for some time filazer for London, Middlesex, Cambridgeshire, and Huntingdonshire; and spent much money in searching records, and writing in favour of the royal prerogative. The only advantage he received for this attachment to the royal cause was the place of commissioner for regulating the law, worth L.200 per annum, but which only lasted two years. After the restoration of Charles II. when the bill for taking away the tenures was depending in parliament, Philips wrote and published a book to show the necessity of preserving them, entitled *Tenenda non Tollenda*, or, the Necessity of preserving Tenures *in capite*, and by Knight's Service, which, according to their first institution, were, and are yet, a great part of the *salus populi*, 1660, in 4to. In 1663 he published the Antiquity, Legality, Reason, Duty, and Necessity of Pre-emption and Purveyance for the King, in 4to; and afterwards many other pieces upon subjects of a similar kind. He assisted Dr Bates in his *Elenchus Motuum*, especially in searching the records and offices for that work, and died on the 17th of November 1690, in his eighty-ninth year. He was a man well acquainted with records and antiquities; but his manner of writing is neither close nor well digested. He published a political pamphlet in 1681, entitled *Ursa Major et Minor*, "showing that there is no such fear, as is fictitiously pretended, of popery and arbitrary power."

Philips, *Ambrose*, an English poet of some note, was descended from an ancient and considerable family of that name in Leicestershire. He received his education at St John's College, Cambridge, and during his stay there wrote his pastorals, which at that time acquired him a high reputation. His next performance was the Life of Archbishop Williams, written, according to Mr Cibber, to make known his political principles, which in the course of it he had an opportunity of doing, as the archbishop, who is the hero of his work, was a strong opponent of the high-church party and their measures.

When he quitted the university and went to London, Philips became a constant attendant at, and one of the wits of, Button's coffee-house, where he obtained the friendship and intimacy of many celebrated men of that age, particularly of Sir Richard Steele, who, in the first volume of his Tatler, has inserted a little poem of Philips's, which he entitles a Winter Piece, dated from Copenhagen, and addressed to the Earl of Dorset, and on which he bestows the highest encomiums; and, indeed, so just are these commendations, that even Pope himself, who had a fixed aversion to the author, whilst he affected to despise his other works, used always to except this from his censure and contempt.

The first dislike Pope conceived against Philips proceeded from that jealousy of fame which was so conspicuous in his character; for Sir Richard Steele had taken so strong a liking to the pastorals of Philips, that he formed a design of instituting a critical comparison of them with those of Pope, in the conclusion of which the preference was to be given to Philips. This design, however, having come to the knowledge of Pope, the latter, who could not bear a rival near the throne, determined to ward off this stroke by a stratagem of the most artful kind; which was no other than taking the same task on himself. Accordingly, in a paper in the Guardian, he drew a similar comparison, and gave a like preference, but on principles of criticism so evidently fallacious, as to point out to all the absurdity of the decision. However, notwithstanding the ridicule which Philips drew upon himself by standing as it were in competition with so powerful an antagonist, it is allowed that in some parts of his pastorals there are certain touches of nature, and a degree of simplicity, which are much better suited to the purposes of pastoral than the more correctly-turned periods of Pope's versification. Philips and Pope being of different political principles, proved another cause of enmity between them, which at length arose to so great a height, that the former, finding his antagonist too hard for him at the weapon of wit, had determined upon making use of a rougher kind of argument; and for this purpose he even went so far as to hang up a rod at Button's for the chastisement of his adversary whenever he should come thither. Pope, however, declining to brave his antagonist, avoided the *argumentum baculinum*, in which he would, no doubt, have found himself on the weaker side of the question. Our author also wrote several dramatic pieces, as the Briton, Distressed Mother, and Humphrey Duke of Gloucester, all of which met with success, and one of them still continues to be a standard entertainment at the theatres, being generally repeated several times in every season. Philips's circumstances were throughout his life not only easy, but rather affluent, in consequence of his being connected, by political principles, with persons of great rank and consequence. He was concerned with Dr Hugh Boulter, afterwards archbishop of Armagh, the Right Honourable Richard West, lord chancellor of Ireland, the Rev. Gilbert Burnet, and the Rev. Henry Stevens, in writing a series of papers under the title of the *Freethinker*, which were all published together by Philips, in three volumes 12mo.

In the latter part of Queen Anne's reign, he was secretary to the Hanover Club, a set of noblemen and gentlemen who had formed an association in honour of that succession, and for the support of its interests, and who used particularly to distinguish in their toasts such of the fair sex as were most zealously attached to the illustrious house of Brunswick. Philips' station in this club, together with the zeal shown in his writings, recommended him to the notice and favour of the new government. Soon after the accession of George I., he was put into the commission of the peace, and appointed one of the commissioners of the lottery; and, on his friend Dr Boulter being made primate of Ireland, he accompanied that prelate across St George's Channel, where considerable preferments were bestowed on him, and he was elected a member of the Irish House of Commons, as representative for the county of Armagh. At length, having purchased an annuity for life of L.400 per annum, he returned to England some time in the year 1748; but being in a very bad state of health, and, moreover, at an advanced age, he died soon afterwards, at his lodgings near Vauxhall, in Surrey.

Philips, *Catharine*, an ingenious lady, the daughter of Mr John Fowler, merchant, was born at London in January 1631, and educated at a school near Hackney. She married James Philips of the priory of Cardigan; and went with the Viscountess of Dungannon into Ireland, where she translated into English Corneille's tragedy of Pompey, which was several times acted there with great applause. She also translated the first four acts of the Horace, another tragedy of Corneille, the fifth being executed by Sir John Denham. This remarkable person died of the small-pox in London on the 22d of June 1664, much and justly regretted; "having," according to Langbaine, "not left any of her sex her equal in poetry." Dr Jeremy Taylor addressed to her his Measures and Offices of Friendship, the second edition of which appeared in the year 1657, in 12mo. Her assumed poetical name was *Orinda*.

Philips, *John*, an English poet of considerable eminence, was born in 1676. He was educated at Winchester and Oxford, where he became acquainted with Milton, whom he studied with great application, and traced in all his successful translations from the ancients. The first poem by which he distinguished himself was his Splendid Shilling, which in the Tatler is styled the "finest burlesque poem in the English language." His next was entitled Blenheim, which he wrote at the request of the Earl of Oxford, and Mr Henry St John, afterwards Lord Bolingbroke, on the victory obtained by the Duke of Marlborough in the year 1704. It was published in 1705; and the year after, he finished another poem upon cider, the first book of which had been written at Oxford. It is on the model of Virgil's Georgics, and is thought a very excellent piece. We have no more of Philips' except a Latin ode to Mr Henry St John, which is esteemed a masterpiece. He was contriving greater things, when he was seized with the illness of which he died, at Hereford, on the 15th of February 1708, before he had attained his thirty-third year.

It deserves to be remarked, that there were other two poets of the same name who flourished in his time. One of these was Milton's nephew, who wrote several things, particularly some memoirs of his uncle, and part of Virgil Travestied. The other was the author of two political farces, which were both printed in 1716, viz. The Earl of Marr Married, with the Humours of Jockey the Highlander; and the Pretender's Flight, or a Mock Coronation, with the Humours of the facetious Harry St John.

PHILISTINES were the ancient inhabitants of Palestine, well known in sacred history. These people are sometimes called in Scripture Cherethites and Caphtorim. The earlier part of their history is, like that of most other nations, very obscure and uncertain. The authors of the Uni-

Philistines.

versal History inform us that they were descended partly from the Casluhim, and partly from the Caphtorim, both being of the progeny of Mizraim, the son of Ham, the son of Noah. Moses tells us that they drove out the Avim or Avites even to Azzah or Gazah, where they settled; but when this happened cannot be determined. Upon the whole, however, our learned authors are clearly of opinion, that the Casluhim and Caphtorim, from whom the Philistines were descended, came originally from Egypt, and called the country which they had conquered by their own name. Many interpreters, however, think that Caphtor was but another name for Cappadocia, which they imagine to have been the original country of the Philistines. But Calmet, in a particular dissertation prefixed to the first book of Samuel, endeavours to show that they were originally from the island of Crete. The reasons which led him to think that Caphtor is the island of Crete may be shortly stated. The Philistines were strangers in Palestine, as appears from various parts of Scripture; and hence the Septuagint always translate this name *strangers*. Their proper name was Cherethim; for Ezekiel, speaking against the Philistines, says, "I will stretch out mine hand upon the Philistines, and I will cut off the Cherethim, and destroy the remnant of the sea-coast." Zephaniah, inveighing against the same people, says, "Woe unto the inhabitants of the sea-coasts, the nation of the Cherethites." And Samuel says, that the Amalekites made an irruption into the country of the Cherethites, that is, of the Philistines, as the sequel of the discourse plainly proves. The kings of Judah had afterwards foreign guards called the Cherethites and Pelethites, who appear to have been Philistines. The Septuagint, under the name of Cherethites, understood the Cretans; and by Cherith they understood Crete. Besides, the Scripture says that the Philistines came from the isle of Caphtor. Now we know of no island in the Mediterranean in which the marks whereby the Scripture describes Caphtor and Cherethim agree better than in the island of Crete. The name Cretim or Cherethim is the same with that of Cretenses; and the Cretans are a most ancient and celebrated people, who inhabited the islands of the Mediterranean, pretending to have been originally produced out of their own soil. This island was well peopled in the time of the Trojan war. Homer calls it the island of the hundred cities. The city of Gaza in Palestine went by the name of Minoa, because Minos, king of Crete, coming into that country, called this ancient city by his own name.

Herodotus acknowledges that the Cretans were originally barbarians, and did not come from Greece. Homer says, that a different language was spoken in the island of Crete; that there were Greeks there, but also true or ancient Cretans, and Pelasgians. The ancient Cretans are the same as the Cherethites, and the Pelasgians as the Philistines or Pelethites of the Scripture. Their language was the same with that of the Canaanites or Phœnicians, that is, Hebrew; and they were descended, as well as Canaan, from Ham, by Mizraim. The manners, arms, religion, and gods of the Cretans and Philistines were the same. Both used only bows and arrows; and Dagon the god of the Philistines was the same as the Dictymna of the Cretans.

Whether these arguments are convincing, it is not for us to determine. Wells does not think they are, being of the same opinion with the authors of the Universal History, who say that Coptus, the name of an old city of Egypt, is a corruption of the ancient Caphtor. It is not, however, of great importance to determine whether they came from Crete, from Cappadocia, or from Egypt. They had certainly been a considerable time in the land of Canaan when Abraham arrived there in the year of the world 2083. They were then a very powerful people, governed by kings, and in possession of several considerable cities. The race of kings then in power were honoured with the title of *Abimelech*. This race, however, was of short duration; for their monarchy became an aristocracy of five lords, who, as far as we can discover, were partly independent of one another, though they acted in concert for the common cause. This form of government was again succeeded by another race of kings, distinguished by the title of *Achish*, though they also bore that of Abimelech. The kings were always subjected to great limitations. The Philistines appear to have been a very warlike people, industrious, and lovers of freedom; they did not circumcise, and in the early periods of their history held adultery in the greatest abhorrence. "Their character," say the authors of the Universal History, "must be considered at different periods; for we may say they were not always the same people. In the days of Abraham and Isaac, they were without all doubt a righteous and hospitable nation; but afterwards a revolution in government, religion, and morals, may have ensued. From thenceforward they became like the other idolatrous nations; the same enormities crept in and prevailed amongst them. They are constantly mentioned in Scripture as strangers; and though possessed of a very considerable part of the Land of Promise, yet God would never suffer them to be driven out, they being Egyptians by descent, and not original natives, whose land only was promised to Abraham and his seed. Their arrogance and ambition were great; and so irreconcileable was their enmity to the Israelites,[1] that one would be almost tempted to think they were created on purpose to be a thorn in their sides; for though the hand of God was evidently against them several times, and particularly when they detained the ark, yet they hardened their hearts and closed their eyes against conviction. They seem to have entertained a very great veneration for their deities, in which they persisted, though they were eye-witnesses of the shame and ignominy which befell them in the presence of the captive ark; nay, they were so biassed in their favour, as to imagine that their gods might prevail against Him who had in so glaring a manner put them to shame and disgrace. They were much engaged in trade, which, considering their situation, they may have exercised from the beginning; but, by the accession of the fugitive Edomites in David's time, they rose to so great a reputation as merchants, that the Greeks, it seems, preferred them to all other nations in that respect, and from them called all the country bordering upon theirs *Palestine*. Their language was not so different from that spoken by the Hebrews as to cause any difficulty for them to converse together, as will be perceived by their intercourse with Abraham and Isaac; so that, in all this region, the several nations spoke one and the same tongue, perhaps with some variation of dialect. They had doubtless the arts and sciences in common with the most learned and ingenious amongst their contemporaries, and perhaps some of them in greater perfection. They had giants amongst them; but whether these were originally of the breed of the Anakim, who retired hither when they were expelled from Hebron, or were sprung from accidental births, is not easily determined. We must not forget, that the invention of the bow and arrow is ascribed to this people.

---

[1] "From a passage in Chronicles, where it is said, that 'the men of Gath slew the children of Ephraim, who would have taken their cattle from them,' it is guessed to have been of very ancient date. This incident is nowhere else to be found; and there are various notions concerning the sense in which we must take this passage. As to the time of the transaction, most people allow it to have been while the children of Israel were sojourners in Egypt. It plainly appears, by the next verse, that Ephraim himself was living at that period. The Targum supposes his children miscomputed the time they were to serve in Egypt, and began too early an attempt upon their promised land."

Philistines.

"Their religion was different at different times; under their first race of kings, they used the same rites with the Hebrews. Abimelech, in the sin he had like to have committed with Sarah, through Abraham's timidity, was favoured with a divine admonition from God; and, by his speech and behaviour at that time, it seems as if he had been used to converse with the Deity. In after times, they fell into endless superstitions, and different kinds of idolatry; nay, each of the principal or five cities seemed to have an idol of its own. Marna, Marnas, or Marnash, was worshipped at Gaza, and is said to have migrated into Crete, and to have become the Cretan Jupiter. Dagon was worshipped at Azotus; he seems to have been the greatest, the most ancient, and most favourite god they had; to which may be added, that he perhaps subsisted the longest of any that did not straggle out of the country. To him they ascribed the invention of bread-corn, or of agriculture, as his name imports. We cannot enter into the common notion of his being represented as a monster, half man, half fish; nor consequently into another, almost as common, that he is the same with the Syrian goddess Derceto, who, we are told, was represented under some such mixed form. Our opinion is, that this idol was in shape wholly like a man; for we read of his head, his hands, and his feet. He stood in a temple at Azotus, and had priests of his own, who paid him a very constant attendance. Next to Dagon was Baalzebub, the god of Ekron. In the text of the New Testament he is called *Beelzebub*, and the 'prince of devils.' His name is rendered *lord of flies*, which by some is held to be a mock appellation bestowed on him by the Jews; but others think him so styled by his worshippers, as Hercules Apomyios and others were, from his driving those insects away; and urge, that Ahaziah, in his sickness, would scarcely have applied to him, if his name had carried in it any reproach. But it must be remembered, it is the sacred historian that makes use of that contemptuous term in derision; whereas the idolatrous monarch, who was one of his votaries, might call him by his common name, supposed to have been *Baal-zeboath*, 'the lord of armies,' or *Baal-shamin*, 'lord of heaven,' or some other bordering on Baal-zebub. How or under what form he was represented is uncertain. Some place him on a throne, and attire him like a king; others paint him as a fly. Not to dwell on this obscurity, it appears that he became an oracle of the highest repute for omniscience and veracity; that he had priests of his own; and that he, in the middle times at least, was much sought after by those who were anxious about futurity. Derceto we take certainly to have been the goddess of Ascalon; but we are supported by profane authority, without the least countenance from Scripture. Gath is seemingly the only city of all the five unprovided with a deity; wherefore, as the Scripture declares, that Ashtaroth, or Astarte, was worshipped by this people, we are ready to place her at Gath, and the rather, as this of all their cities may have had most communication with Sidon. To speak in general concerning their religious rites and ceremonies, which is all we can do, they seem to have erected very large and spacious temples, or very wide halls, for the celebration of their solemn seasons and festivals (for such they surely had); their religious offices were attended with much pomp, and a great concourse from all parts; and they presented their gods with the chief part of their spoil, and carried them about with them when they went to war. We do not find in Scripture that they sacrificed their children; and yet the Curetes are said to be their descendants."

With respect to the history of this extraordinary people, we find from the above extract, that they were not comprehended in the number of nations devoted to extermination, and whose territory the Lord had abandoned to the Hebrews; nor were they of the cursed seed of Canaan. However, Joshua did not forbear to give their lands to the Hebrews, and to set upon them by command of the Lord, because they possessed a country which was promised to the people of God. But these conquests of Joshua must have been ill maintained, since under the Judges, under Saul, and at the beginning of the reign of David, the Philistines oppressed the Israelites. It is true that Shamgar, Samson, Samuel, and Saul, made head against them, but did not reduce their power; and they continued independent down to the reign of David, who subjected them to his government.

They remained in subjection to the kings of Judah down to the reign of Jehoram, the son of Jehoshaphat, that is, for about 246 years. However, Jehoram made war against them, and probably reduced them to obedience; because it is observed in Scripture that they revolted again under Uzziah, and that this prince kept them to their duty during the remainder of his reign. During the unfortunate reign of Ahaz, the Philistines made great havoc in the territories of Judah; but his son and successor Hezekiah subdued them. Lastly, they regained their full liberty under the latter kings of Judah; and, by the menaces denounced against them by the prophets Isaiah, Amos, Zephaniah, Jeremiah, and Ezekiel, we find that they had brought a thousand hardships and calamities upon the children of Israel, for which cruelties God threatened to punish them. Esarhaddon besieged Ashdod or Azoth, and took it; and, according to Herodotus, Psammeticus king of Egypt took the same city, after a siege of twenty-nine years. There is great probability that Nebuchadnezzar, when he subdued the Ammonites, Moabites, Egyptians, and other nations bordering upon the Jews, also reduced the Philistines. After this, they fell under the dominion of the Persians, and then under that of Alexander the Great, who destroyed the city of Gaza, the only city of Phœnicia which ventured to oppose him. After the persecution of Antiochus Epiphanes, the Asmonæans subjected to their sway several cities of the Philistines; and Tryphon gave to Jonathan Maccabæus the government of the whole coast of the Mediterranean, from Tyre as far as Egypt, thus including all the country of the Philistines.

PHILISTUS, a celebrated historian of Syracuse, who was an active partisan of Dionysius the elder, and was by him made governor of the citadel, B. C. 406. Having dared to marry a relation of the tyrant without his knowledge, he was compelled to fly, and took refuge in the city Adria, in the north of Italy, where he employed himself in writing the history of his native island. Philistus tried to procure his recall, by representing the government of Dionysius in a very favourable light; but the prince refused to listen to his entreaties; and it was not till the accession of Dionysius the younger that he returned to his native country. It is said that the political party in Syracuse which supported despotic principles were afraid of the influence that Plato might have over the mind of Dionysius; and as Philistus had always been a strenuous assertor of arbitrary power, and was, besides, possessed of considerable talents, it was thought that he might have been made use of to counteract the effects of Plato's eloquence. Philistus was killed, B. C. 356, by the Syracusans. He wrote a history of Sicily, the first part of which was contained in seven books, and extended over a period of eight hundred years, terminating with the siege of Agrigentum, B. C. 406. The second part contained the history of the elder Dionysius to B. C. 368, and he gave, in two books, the reign of Dionysius the younger till B. C. 363.

PHILO, an ancient Greek writer, descended of a noble family amongst the Jews, flourished at Alexandria during the reign of Caligula. He was the chief of an embassy sent to Rome about the year forty-two, to plead the cause of the Jews against Apion, who had been sent by the Alexandrians to charge them with neglecting the honours due to Cæsar. Caligula, however, would not allow him to speak, and behaved to him in such a manner that Philo was in considerable danger of losing his life. Others, again, tell us that he was heard, but that his demands were refused. He afterwards went to Rome in the reign of Claudius, and both Eusebius and Jerome inform us that he became acquainted with St Peter, with whom he lived on terms of friendship. Photius adds, that he became a Christian, but afterwards, from some motive of resentment, recanted. All this, however, is uncertain, because the precise period at which St Peter visited Rome has not been ascertained.

Philo was educated at Alexandria, and made very great progress in eloquence and in philosophy. After the fashion of the time, he cultivated, like many of his nation and faith, the philosophy of Plato, whose principles he so thoroughly imbibed, and whose manner he so well imitated, that it became a common saying, *Aut Plato philonizat, aut Philo platonizat.* Josephus describes him as a man "eminent on all accounts;" and Eusebius represents him as "copious in speech, rich in sentiments, and sublime in the knowledge of Holy Writ." He was, however, so much immersed in philosophy, particularly the Platonic, that he neglected the Hebrew language, and also the rites and customs of his own people. Scaliger alleges, that Philo knew no more of Hebrew and Syriac than a Gaul or a Scythian. Grotius is of opinion that he is not fully to be depended on in what relates to the manners of the Hebrews; and Cudworth declares that, though a Jew by nation, he was yet very ignorant of Jewish customs. But Fabricius thinks differently; for although he admits the inadvertencies and errors of Philo in regard to these matters, he does not discover sufficient reason to justify charging so illustrious a doctor of the law with ignorance. He allows, however, that Philo's passion for philosophy had made him more than half a Pagan. It led him to interpret the whole of the law and the prophets upon Platonic ideas, and to admit nothing as truly interpreted which was not agreeable to the principles of the Academy. Besides, he turned every thing into allegory, and deduced the darkest meanings from the plainest words. This pernicious practice Origen is known to have imitated, and thus exposed himself to the scoffs of Celsus and of Porphyry. Philo's writings abound with high and mystical, as well as subtile, far-fetched, and abstracted notions; and indeed the doctrines of Plato and Moses are so promiscuously blended, that it is not easy to assign to each his peculiar prerogatives. In his works, however, there are certainly many excellent things. Though he is continually platonizing and allegorizing the Scriptures, he abounds with fine sentiments and lessons of morality; and his morals are rather the morals of a Christian than those of a Jew. History, as well as his own writings, give us every reason to believe that he was a man of great prudence, constancy, and virtue.

His works were first published in Greek by Turnebus, at Paris, 1552; and to these a Latin translation, executed by Gelenius, was afterwards added. The Paris edition of 1640, in folio, is the best that was published for a century; a circumstance which led Cotelerius to observe, that Philo was an author who deserved to have a better text and a better version. This, however, was accomplished, in 1742, when a handsome edition of his works was published at London, by Dr Mangey, in two vols. folio. In 1797, Jacob Bryant published the Sentiments of Philo Judæus concerning the *Logos* or Word, in order to prove that Philo borrowed his sentiments and expressions relative to the second person of the adorable Trinity from the apostles. But it is to be observed here, that Philo's authority had repeatedly before been founded on by various writers in favour of the fundamental principle of the existence of a Divine Unity in a Trinity of Persons; particularly by Dr Allix in his Judgment of the Jewish Church, 1699, and also by Mr Whitaker in his Origin of Arianism Disclosed, 1791.

Philo, a native of Byblos, in Syria, is believed by Vossius to have been born in the tenth year of the reign of Tiberius, A. D. 24, and to have lived to the times of the Emperor Hadrian, who succeeded to the empire A. D. 117. He gained considerable reputation as a writer both of history and grammar; but his name has come down to us chiefly as the translator of a history which Sanchoniathon had written in the Phœnician language. Eusebius has preserved several fragments of the preface of Philo, and also of this history. This fragment has called forth the ingenuity of many modern writers, but more particularly of Mr Dodwell, who has written a very learned dissertation on the subject. Fourmont also makes it the text of a work which he entitled *Réflexions Critiques sur les Histoires des anciens Peuples*, two vols. 4to.

Philo, a celebrated writer on mechanics, was a native of Byzantium, and flourished in the year 160, being the contemporary of Ctesibius and Hero. He was the author of a work entitled *Poliorcetica*, on the method of attacking and defending towns, of which the fourth and fifth books have been preserved. The first treats of the manner of preparing arrows, balistæ, catapultæ, and other warlike engines. Amongst other inventions, he mentions a machine of Ctesibius which discharged weapons by means of compressed air, upon the same principle, no doubt, as our air-gun. In the second book he treats of the manner of fortifying and provisioning cities, and, amongst other things, recommends that the provisions and water be poisoned if there be danger of the place falling into the hands of an enemy. This work has been published, with a Latin translation, in a collection entitled *Veterum Mathematicorum Opera*, Par. 1693. The invention of the air-gun has been treated of by Alb.-Louis Meister, *De Catapulta polybola Commentatio qua locus Philonis Mechanici, in libro iv. de telorum constructione certans illustratur*, Göttingen, 1768. There is another little work attributed to Philo, entitled *De septem Orbis Spectaculis*, part of the sixth chapter of which, and the whole of the seventh, are lost. It has been published, with a Latin translation, and many learned notes, by J. C. Orelli, Leipzig, 1816, 8vo.

PHILOLAUS, of Crotona, was a celebrated philosopher of antiquity, of the school of Pythagoras, to whom that philosopher's *Golden Verses* have been ascribed. As he made the heavens the principal object of contemplation, it has been idly supposed that he was the author of the true system of the world, which Copernicus afterwards revived. This notion led Bullialdus to place the name of Philolaus at the head of two works written expressly to illustrate and defend that system.

PHILOLOGY.

Definition.

Philology is compounded of the two Greek words φιλος and λογος and imports the desire of investigating the properties and affections of *words*. The sages of Greece were, in the most ancient times, denominated σοφοι, that is, wise men. Pythagorus renounced this pompous appellation, and assumed the more humble title of φιλοσοφος, that is, a lover of wise men. The learned Greeks were afterwards called philosophers; and in process of time, in imitation of this epithet, the word *philologer* was adopted, to import a man deeply versed in languages, etymology, and antiquities. Hence the term *philology*, which denotes the science that we propose briefly to discuss in the following article.

Objects and uses of philology.

Although philology, in its original import, denoted only the study of words and language, it gradually acquired a much more extensive, and at the same time a much more useful, as well as more exalted, signification. It comprehended the study of grammar, criticism, etymology, the interpretation of ancient authors, antiquities; and, in a word, every thing relating to ancient manners, laws, religion, government, and language. In this enlarged sense of the word, philology becomes a science of the greatest utility; it opens a wide field of intellectual investigation, and indeed calls for a more intense exertion of industry, and multifarious erudition, than most of those departments of literature which custom has dignified with more high-sounding names. It is indeed apparent, that, without the aid of philological studies, it is impossible upon many occasions, to develope the origin of nations; to trace their primary frame and constitution; to discover their manners, customs, laws, religion, government, language, progress in arts and arms; or to learn by what men and what measures the most celebrated states of antiquity rose into grandeur and consideration. The study of history, so eminently useful to the legislator, the divine, the military man, the lawyer, the philosopher, and the private gentleman who wishes to employ his learned leisure in a manner honourable and improving to himself, and useful to his country, will contribute very little towards enlightening the mind without the aid of philological researches. For these reasons we shall endeavour to explain the various branches of that useful science as fully, and intelligibly as the nature of the present undertaking will permit.

Object of this article.

Most of the branches of philology have already been treated of under the heads of GRAMMAR and LANGUAGE. But there still remains one part, which has either been slightly touched upon, or totally omitted, under the foregoing topics; we mean, the nature and complexion of most of the oriental tongues, as also some of the radical dialects of the languages of the west. As we would willingly gratify our readers of every description to the utmost of our power, we shall endeavour in this place to communicate to them as much information upon that subject as the extent of our reading, and the limits prescribed for a single article, will permit.

Before entering upon this subject, however, we must observe, that it is not our intention to fill our pages with a tedious, uninteresting, catalogue of barbarous languages, spoken by savage and inconsiderable tribes, of which little, or perhaps nothing, more is known than barely their names. Such an enumeration would swell the article without communicating one single new idea to the reader's antecedent stock. We shall therefore confine our inquiries to such languages as have been used by considerable states and societies, and which of consequence have acquired a high degree of celebrity in the regions of the east.

Variety of dialects before the deluge.

What was the antediluvian language, or whether it was divided into a variety of dialects as at this day, can only be determined by the rules of analogy; and these will lead us to believe, that whatever might have been the primitive language of mankind, if human nature was then constituted as it is at present, a great variety of dialects must of necessity have sprung up in the space of nearly two thousand years. If we adopt the Mosaic account of the antediluvian events, we must admit that for several ages the descendants of Cain lived separated from those of Seth. Their manner of life, their religious ceremonies, their laws, their form of government, were probably different, and these circumstances would of course produce a variety in their language. The posterity of Cain were an inventive race. They found out the arts of metallurgy, music, and some think of weaving; and in all probability many other things conducive to the ease and the accommodation of life were the produce of their ingenuity. A people of this character must have paid no small regard to their words and modes of expression. Wherever music is cultivated, language will naturally be improved and refined. When new inventions are introduced, a new race of words and phrases of necessity spring up, corresponding to the recent stock of ideas to be intimated. Besides, amongst an inventive race of people, new words would be continually fabricated, in order to supply the deficiencies of the primitive language, which was probably scanty in its vocabulary, and its phraseology unpolished. The Cainites, then, amongst their other improvements, cannot well be supposed to have neglected the cultivation of language.

Origin of writing.

Many conjectures have been hazarded both by ancient and modern authors respecting the origin of writing; an art which is nearly connected with that of speaking. According to Pliny,[1] "the Assyrian letters had always existed; some imagined that letters had been invented by the Egyptian Mercury; others ascribed the honour of the invention to the Syrians." The truth seems to be, that letters were an antediluvian invention, preserved amongst the Chaldeans or Assyrians, who were the immediate descendants of Noah, and inhabited those very regions in the neighbourhood of which the ark rested, and where that patriarch afterwards fixed his residence. The circumstance, we think, affords a strong presumption that the use of letters was known before the deluge, and transmitted to the Assyrians and Chaldeans by Noah their progenitor, or at least by their immediate ancestors of his family. If, then, the art of writing was an antediluvian invention, we think that in all probability it originated amongst the posterity of Cain.

The descendants of Seth, according to the oriental tradition, were chiefly addicted to agriculture and the tending of cattle. They devoted a great part of their time to the exercises of piety and devotion. From this circumstance they came to be distinguished by the title of the *sons of God.*[2]

---

[1] *Nat. Hist.* lib. vii. cap. 56.

[2] From this passage (Gen. vi. 2.) misunderstood, originated the absurd idea of the connection between angels and mortal women. (See Josephus, *Antiq. Jud.* lib. i. cap. 4. and Eusebius, *Chron.* lib. i.) The Fathers of the church, almost without exception, adopted this foolish notion. (See also *Philo-Jud.* p. 198, edit. Turn. Paris, 1552.)

According to this description, the Sethites were a simple,[1] unimproved race of people till they mingled with the race of Cain; after which period they at once adopted the improvements and the vices of that wicked family.

It is not, probable, however, that all the descendants of Seth, without exception, mingled with the Cainites. That family of which Noah was descended had not incorporated with the race of Cain. According to the sacred historian, it was lineally descended from Seth, and had preserved the worship of the true God, when, it is probable, the greatest part of mankind had apostatised and become idolaters.[2] Along with the true religion, the progenitors of Noah had preserved that simplicity of manners and equability of character which had distinguished their remote ancestors. Agriculture and the rearing of cattle had been their favourite occupations. Accordingly we learn, that the patriarch Noah, immediately after the deluge, became a husbandman, and "planted a vineyard." The chosen patriarchs, who doubtless imitated their pious ancestors, were shepherds, and employed in the rearing and tending of cattle. Indeed there are strong presumptions that the Chaldeans, Assyrians, Syrians, Canaanites, and Arabians, in the earliest ages followed the same profession.

From this deduction, we imagine, it is at least probable, that the ancestors of Noah persisted in the observance of the same simplicity of manners which had been handed down from Adam to Seth, and from him to Enoch, Methuselah, Lamech, and from this last to Noah himself. According both to scripture and tradition, innovations were the province of the Cainites, whilst the descendants of Seth adhered to the primitive and truly patriarchal institutions.

he origi- l lan- age pre- rved in e family ience oah rung.

If these premises are allowed the merit of probability, we may justly infer that the language of Noah, whatever it was, differed very little from that of Adam;[3] and that if it is possible to ascertain the language of the former, that of the latter will of course be discovered. We shall then proceed to throw together a few observations relating to the language of Noah, and leave our readers to judge for themselves. We believe it will be superfluous to suggest, that our intention in the course of this deduction is, if possible, to trace the origin and antiquity of the Hebrew tongue; and to try to discover whether that language, or any of its sister dialects, may claim the honour of being the original language of mankind.

Whatever may have been the dialect of Noah and his family, that same dialect, according to the Mosaic account, must have obtained, without any alteration, until the era of the building of the tower of Babel. Upon this occasion a dreadful convulsion took place; the language of mankind was confounded, and men were scattered abroad upon the face of all the earth.

onfusion the ver of bel.

How far this catastrophe[4] extended, it is not the business of the present inquiry to determine. But one thing is certain beyond all controversy, namely, that the languages of all the nations which settled near the centre of population were but slightly affected by its influence. A very judicious writer has observed,[5] that three thousand years afterwards, the inhabitants of those countries exhibited a very strong resemblance of cognation, "in their *language*, manner of living, and the lineaments of their bodies." At the same time he observes, that "the resemblance in all those particulars was most remarkable amongst the inhabitants of Mesopotamia." This observation, with respect to language, will, we doubt not, be vouched by every one of our readers who has acquired even a superficial knowledge of the languages current in those countries at a very early period.

It appears, then, that the languages of the Armenians, Syrians, Assyrians, Arabians, and probably of the Chanaanim, did not suffer materially by the confusion of tongues. This observation may, we imagine, be extended to many of the dialects spoken by the people who settled in those countries not far distant from the region where the sacred historian has fixed the original seat of mankind after the deluge.[6] The inference then is, that if Noah and his family spoke the original language of Adam, as they most probably did, the judgment which effected the confusion of tongues did not produce any considerable alteration in the language of such of the descendants of Noah as settled near the region where that patriarch had fixed his residence after he quitted the ark.

A part only of mankind engaged in building the tower.

But supposing the changes of language produced by the catastrophe at the building of the tower as considerable as has ever been imagined, it does not, after all, appear certain, that all mankind, without exception, were engaged in this impious project. If this assertion should be well-founded, the consequence would be, that there was a chosen race who did not engage in that enterprise. If there was such a family, society, or body of men, it must follow, that this family, society, or body of men, retained the language of its great ancestor without change or variation. That such a family did actually exist, is highly probable, for the following reasons.

1. We think there is reason to believe that Ham, upon the heavy curse denounced upon him by his father,[7] retired from his brethren, and fixed his residence elsewhere. Accordingly we find his descendants scattered far and wide, at a very great distance from the Gordyæan mountains, where the ark is generally supposed to have rested immediately after the Flood. Some of them we find in Chaldæa, others in Arabia Felix, others in Ethiopia,[8] others in Canaan, and others in Egypt; and, finally, multitudes were scattered over all the coast of Africa. Between these countries were planted many colonies of Shemites, in Elam, Assyria, Syria, Arabia, &c. We find, at the same time, the descendants of Shem and Japhet settled, in a great degree, contiguous to each other. This dispersion of the Hamites, irregular as it is, can scarcely, we think, have been accidental; it must have been owing to some uncommon cause, and none seems more probable than that assigned above. If, then, the descendants of Ham separated early, and took different routes, as from their posterior situations it appears they did, they could not all be present at the building of the tower.

The descendants of Shem not concerned in this project.

2. It is not probable that the descendants of Shem were engaged in this undertaking, since we find that they were not scattered abroad upon the face of all the earth. The children of Shem were Elam, Ashur, Arphaxad, Lud, and Aram.[9] Elam settled near the mouth of the river Tigris, in the country which, by the Gentile writers, was called *Ely-*

---

[1] The orientals, however, affirm, that Seth, whom they call *Edris*, was the inventor of astronomy.

[2] We think it highly probable that idolatry was established before the deluge, because it prevailed almost immediately after that catastrophe. See POLYTHEISM.

[3] For some conjectures respecting the language first communicated to Adam, see the article on LANGUAGE, and also Schuckford's *Connect.* vol. i. lib. ii. p. 111. *et seq.*

[4] Josephus and the Fathers of the church tell us, that the number of languages produced by the confusion of tongues was seventy-two; but this is a mere rabbinical legend.

[5] Strabo.

[6] The language of the Medes, Persians, Phœnicians, and Egyptians, very much resembled each other in their original complexion; and all had a strong affinity to the Hebrew, Chaldaic, Syriac, &c. (See Walton's *Prolegomena*, Gale's *Court of the Gentiles*, vol. i. lib. i. ch. 11, p. 70, *et seq.*; Bochart, *Phaleg* and *Chanaan*, pass.) To these we may add the Greek language, as will appear more fully below.

[7] Gen. ix. 25.

[8] Josephus informs us, that all the nations of Asia called the Ethiopians *Cushim*, (lib. i. cap. 7.)

[9] Gen. x. 22.

mais. Above him, on the same river, lay the demesne of Ashur, on the western side. In like manner, upon the same river, above him, was situated Aram, who possessed the country of Aramea; and opposite to him was Arphaxad, or Arbaces, or Arbaches, whose country was denominated *Arphachites.* Lud, as some think, settled in Lydia, amongst the sons of Japhet; but this opinion seems to be without foundation.[1] Here, then, there is a dispersion, but such as must have originated from the nature of the thing. The four, or rather the five brothers, all settled contiguously, without being scattered abroad upon the face of the whole earth. Besides, there was no confusion of language amongst these tribes, who continued to use one and the same tongue through many succeeding generations.

From these circumstances it appears, that the posterity of Shem were not involved in the guilt of the builders of the tower, and consequently did not undergo their punishment. If then the language of the Shemites was not confounded upon the erection of the tower, the presumption is, that they retained the language of Noah, which, in all probability, was that of Adam. Some dialectical differences would in process of time creep in, but the radical fabric of the language would remain unaltered.

Language of Adam preserved down to Abraham.

3. The posterity of Shem appear in general to have followed the pastoral life. They imitated the style of living adopted by the antediluvian posterity of Seth. No sooner had Noah descended from the ark, than he became *Ish ha Adamah*, "a man of the earth," that is, a husbandman, and planted a vineyard. We find that some ages afterwards, Laban the Syrian had flocks and herds; and that the chief wealth of the patriarch Abraham and his children consisted in their flocks and herds. Even his Gentile descendants, the Ishmaelites and Midianites, seem to have followed the same occupation. But people of this profession are seldom given to changes. Their wants are few, and consequently they are under few or no temptations to deviate from the beaten track. This circumstance renders it probable that the language of Noah, the same with that of Adam, was preserved with little variation amongst the descendants of Arphaxad down to Abraham.

We have observed above, that Ham, upon the curse denounced against him by his father, very probably left the society of his other brothers, and emigrated elsewhere, as Cain had done in the antediluvian world. There is a tradition still current in the east, and which was adopted by many of the Christian fathers,[2] that Noah, in the nine hundredth and thirtieth year of his life, by divine appointment, did, in the most formal manner, divide the whole terraqueous globe amongst his three sons, obliging them that they would take an oath to stand by the decision. Upon this happened a migration at the birth of Peleg, that is, about three centuries after the Flood. It is affirmed that Nimrod the arch rebel disregarded this partition, and encroached upon the territory of Ashur, which occasioned the first war after the deluge.

The Greeks had acquired some idea of this partition, which they supposed to have been between Jupiter, Neptune, and Pluto.[3] Plato seems to have heard of it;[4] "for," says he, "the gods of old obtained the dominion of the whole earth, according to their different allotments; and this was effected without any contention, for they took possession of their several provinces in a fair and amicable way, by lot." Josephus,[5] in his account of the dispersion of mankind, plainly insinuates a divine destination; and Philo-Judæus[6] was of the same opinion before him.

In consequence of this arrangement, the sons of Shem possessed themselves of the countries mentioned in the preceding pages; the posterity of Japhet had spread themselves towards the north and west; but the Hamites, who had separated from their brethren in consequence of the curse, not choosing to retire to their quarters, which were indeed very distant from the place where the ark rested,[7] seized upon the land of Canaan. Perhaps, too, it might be suggested by some malicious spirits, that the aged patriarch was dealing partially when he assigned to Ham and his posterity a quarter of the world to inhabit, not only remote from the centre of population, but likewise sequestered from the rest of mankind.[8]

But be this as it may, the children of Ham removed eastward, and at length descending from the Carduchean or Gordyæan mountains, directed their course westward, and arrived at the plains of Shinar, which had been possessed by the Ashurim ever since the era of the first migration at the birth of Peleg. The sacred historian informs us, that the whole earth was of one language and of one speech; that in journeying from the east, they lighted upon the plain of Shinar, and dwelt there. In this passage we find no particular people specified; but as we find Nimrod, one of the descendants of Ham, settled in that country, we may be sure that they were the offspring of that patriarch. It would not, we think, be easy to assign a reason how one branch of the family of Ham came to plant itself in the midst of the sons of Shem by any other means but by violence.

The tower of Babel built by the children of Ham.

It is indeed generally supposed, that Nimrod, at the head of a body of the children of Ham, made war upon Ashur, and drove him out of the country of Shinar, and there laid the foundation of that kingdom, the beginning of which was Babel; that this chief, supported by all the Cushites, and a great number of apostates from the families of Shem and Japhet who had joined him, refused to submit to the divine ordinance by the mouth of Noah, with respect to the partition of the earth; and that he and his adherents were the people who erected the celebrated tower, in consequence of a resolution which they had formed to keep together, without repairing to the quarters assigned them by the determination of Heaven. This was the crime which brought down the judgment of the Almighty upon them, by which they were scattered abroad upon the face of all the earth. The main body of the children of Shem and Japhet were not engaged in this impious undertaking; their language, therefore, was not confounded, nor were they themselves scattered abroad. Their habitations were contiguous, those of the Shemites towards the centre of Asia; the dwellings of Japhet were extended towards the north and north-west; and the languages of both these families continued for many ages without the least variation, except what time, climate, laws, religion, new inventions, arts, sciences, and commerce, will produce in every tongue in a succession of years.

---

[1] The ancient name of Lydia was Mæonia. (See Strabo *Casaub.* lib. xiii. p. 586, chap. 7. *Rhod.* 577.) The Lydians were celebrated for inventing games; on which account they were nicknamed by the Æolian Greeks Λυδοι, *Lydi* or *Ludi*, from the Hebrew word LUTZ, *ludere, illudere, deridere.* We find (Ezek. xxvii. 10.) the men of Elam and the men of Lud joined in the defence of Tyre; which seems to intimate, that the Elamites and Ludim were neighbours. If this was actually the case, then Lud settled in the same quarter with his brothers.

[2] Epiphan. (vol. i. p. 5. *ibid.* p. 709.) where our learned readers will observe some palpable errors about *Rhinocorura*, &c. (Eusebius, *Chron.* p. 10. Syncellus, p. 89. Cedrenus *Chron. Pasch.* &c.)

[3] Callimach. *Hym.* Hom. *Iliad*, lib. xv.

[4] Critias, vol. iii. p. 109. *Serr.* Apollodorus mentions a time when the gods respectively selected particular cities and regions, which they were to take under their peculiar protection.

[5] *Antiq. Jud.* lib. i. c. 5.

[6] Lib. x. p. 236. Turn. Paris, 1552. We have a plain allusion to this distribution in Deuteronomy (xxxii. 7.) "When the Most High divided to the nations their inheritance, when he separated the sons of Adam, he set the bounds of the people, according to the number of the children of Israel; for the Lord's portion is his people; Jacob is the lot of his inheritance." From this passage it appears, that the whole was arranged by the appointment of God, and that the land of Canaan was expressly reserved for the children of Israel. St. Paul (Acts xvii. 16.) speaks of this divine arrangement, "God made of one blood all nations of men, that dwell on the face of the earth; and determined the bounds of their habitation."

[7] The ark, according to the most probable accounts, rested upon Mount Ararat in Armenia.

[8] We think it by no means improbable that Noah, well knowing the wickedness of the family of Ham, and especially their inclination to the idolatry of the antediluvians, might actually intend to separate them from the rest of mankind.

The general opinion then was, that none but the progeny of Ham and their associates were present at the building of the tower, and that they only suffered by the judgment consequent upon that attempt.[1] There are even amongst the pagans some allusions to the division of the world amongst the three sons of Noah. Many of the learned have imagined that this patriarch was Saturn, and that his three sons were Jupiter, Neptune, and Pluto, as has been observed above.

Berosus, in his history of the Babylonians, informs us, that Noah, at the foot of Mount Baris or Luban, where the ark rested, gave his children their last instructions, and then vanished out of sight.[2] It is now generally believed that the Xisuthrus of Berosus was Noah. Eupolemus, another heathen writer, tells us, "that the city Babel was first founded, and afterwards the celebrated tower; both which were built by some of those people who escaped the deluge. They were the same with those who in after times were exhibited under the name of *giants*. The tower was at length ruined by the hand of the Almighty, and those giants were scattered over the whole earth."[3] This quotation plainly intimates, that according to the opinion of the author, only the rascally mob of the Hamites, and their apostate associates, were engaged in this daring enterprise.

Indeed, it can never be supposed that Shem, if he was alive at that period, as he certainly was, would co-operate in such an absurd and impious undertaking. That devout patriarch, we think, would rather employ his influence and authority to divert his descendants from an attempt which he knew was undertaken in contradiction to an express ordinance of Heaven; and it is surely very improbable that Elam, Ashur, Arphaxad, and Aram, would join that impious confederacy, in opposition to the remonstrances of their father.

The building of the tower, according to the most probable chronology, was undertaken at a period so late, that *all mankind* could not possibly have concurred in the enterprise.

Many of the fathers were of opinion, that Noah settled in Armenia, the country where the ark rested; and that his descendants did not leave that region for five generations,[4] or during the space of 659 years. By this period the human race must have been so amazingly multiplied, that the plains of Shinar could not have contained them. According to the Samaritan Pentateuch, and the Septuagint version, Peleg was born in the 134th year of his father Eber. Even admitting the vulgar opinion, that the tower had begun to be built, and the dispersion consequent upon that event must have taken place at this era, the human race would have been by much too numerous to have universally concurred in one common design.

From these circumstances, we hope it appears that the whole mass of mankind was not engaged in building the tower of Babel; that the language of all the human race was not confounded upon that occasion; and that the dispersion reached only to a combination of Hamites, and of the most profligate part of the two other families, who had joined their wicked confederacy.

The original language preserved in the other two families.

We have pursued this argument to considerable length, because some have inferred, from the difference in languages existing at this day, that mankind cannot have sprung from two individuals; because from the connection still existing amongst languages, some have been bold enough to question the fact, though plainly recorded in sacred history; and lastly, because we imagine that some of our readers, who do not pretend to peruse the writings of the learned, may be gratified by seeing the various opinions respecting the confusion of tongues, and the dispersion of mankind, collected into one mass, equally brief, we hope, and intelligible. And this view of these opinions, with the foundations on which they respectively rest, we think may suffice to prove, that the language of Noah was for some ages preserved, unmixed, amongst the descendants of both Shem and Japhet.

To gratify still further such of our curious readers as may not have access to more ample information, we shall in this place exhibit a brief detail of the circumstances which attended this fatal attempt. The people engaged in it have been held up as a profligate race. The Almighty himself denominates them "*the children of men*," which is the very appellation by which the antediluvian sinners were characterised; *the sons of God saw the daughters of men*, &c. Their design in raising this edifice was, "*to make them a name, and to prevent their being scattered abroad upon the face of the whole earth*."[5]

Whatever resolution the rest of mankind might take, they had determined to maintain themselves on that spot. The tower was intended as a centre of union, and perhaps as a fortress of defence. Such a stupendous fabric, they imagined, would immortalize their memory, and transmit the name of their confederacy with distinction to future ages.[6] The design plainly intimates, that there was only a party concerned in the undertaking, since, had all mankind been engaged in it, the purpose would have been foolish and futile. Again, they intended, by making themselves *a name*, to prevent their being scattered abroad upon the face of the earth. This was an act of rebellion in direct contradiction to the divine appointment, which constituted their crime, and brought down the judgment of Heaven upon their guilty heads. But the consequence of the confusion of languages was, that the projectors left off building, and were actually scattered abroad, contrary to their intention.

Pagan tradition concerning Babel.

Abydenus, in his Assyrian Annals, records, that the tower was carried up to heaven; but that the gods ruined it by storms and whirlwinds, and overthrew it upon the heads of those who were employed in the work, and that the ruins of it were called *Babylon*.[7] Before this there was but one language subsisting amongst men; but now there arose πολυθρηφωνη, *a manifold speech;* and he adds, that a "war soon after broke out between Titan[1] and Kronos."[2] The Sybilline oracles give much the same account of this early and important transaction.

---

[1] Some learned men have imagined that this confusion of language, was only a temporary failure of pronunciation, which was afterwards removed. This they are led to conclude, from the agreement of the languages of these people in after times.

[5] Gen. chap. xi.

[6] Many foolish and absurd notions have been entertained concerning this structure. Some have imagined that they meant to take shelter there in case of a second deluge; others, that it was intended for idolatrous purposes; others, that it was to be employed as an observatory. Its dimensions have likewise been most extravagantly magnified. Indeed Strabo, lib. 16, mentions a tower of immense size remaining at Babylon in his time, the dimensions of which were a stadium every way. This, however, seems to have been the remains of the temple of Bel or Belus.

[7] See the Greek original of this quotation, Euseb. *Chron.* lib. i. p. 73.

Justin[3] informs us, that the Phœnicians who built Tyre, were driven from Assyria by an earthquake. These Phœnicians were the descendants of Mizraim the youngest son of Ham; they were, we think, confederates in building the tower, and were driven away by the catastrophe that ensued. Many other allusions to the dispersion of this branch of the family occur in pagan authors, but the limits to be observed in an inquiry of this nature oblige us to omit them, on the whole, we think it probable that the country of Shinar lay desolate for some time after this revolution; for the dread of the judgment inflicted upon the original inhabitants would deter men from settling in that inauspicious region. At last, however, a new colony arrived, and Babel, or Babylon, became the capital of a flourishing kingdom.

Our readers, we believe, will expect that we should say something of Nimrod the mighty hunter, who is generally thought to have been deeply concerned in the transactions of this period. According to most authors, both ancient and modern, this patriarch was the leader of the confederates who erected the tower, and the chief instigator to that enterprise. But if the tower was built at the birth of Pheleg, according to the Hebrew computation, that chief was either a child,[4] or rather not born at that period.[5] The Seventy have pronounced him a giant, as well as a huntsman. They have translated the Hebrew word *Gebur*, which generally signifies strong, mighty, by the word γιγας, giant; an idea which we imagine those translators borrowed from the Greeks. The antediluvian giants are called *Nephelim* and *Rephaim*, but never *Geburim*. The Rabbinical writers, who justly hated the Babylonians, readily adopted this idea;[6] and the Fathers of the church, and the Byzantine historians, have universally followed them. He has been called *Nimrod*, *Nebrod*, *Nymbroth*, *Nebroth*, and *Nebris*. Not a few have made him the first Bacchus, and compounded his name of *Bar*, a son, and *Cush*, that is the son of *Cush*. Some have imagined that he was the Orion of the pagans, whose shade is so nobly described by Homer.[7] But the etymology of this last name implies something honourable, and very unsuitable to the idea of the tyrant Nimrod.[8] It must be observed, however, that we find nothing in Scripture to warrant the supposition of his having been a tyrant; so far from it, that some have deemed him a benefactor to mankind.[9]

The beginning of this prince's kingdom was Babel. Eusebius gives us first[10] a catalogue of six kings of the Chaldeans, and then another of five kings of Arabian extraction, who reigned in Chaldæa after them. This might naturally enough happen, since it appears that the inhabitants of those parts of Arabia which are adjacent to Chaldæa were actually Cushites, of the same family with the Babylonians.[11]

The Cushites, however, were at last subdued, perhaps partly expelled Chaldæa by the *Chasiaim*, who probably claimed that territory as the patrimony of their progenitors. That the Chasidim were neither Cushites, nor indeed Hamites, is obvious from the name. The Hebrews, and indeed all the Orientals,[12] denominated both the people who inhabited Arabia, *Cushim*, and also the Ethiopians who sprung from the last-mentioned people. Had the later inhabitants of Chaldæa been the descendants of Cush, the Jewish writers would have called them Cushim. We find they called the Phœnicians *Chanaanim*, the Syrians *Aramim*, the Egyptians *Mizraim*, the Greeks *Jonim*, and so on. The Chasidim, therefore, or modern inhabitants of Chaldæa, were positively descended of one Chesed or Chased; but who this family-chief was, it is not easy to determine. The only person of that name whom we meet with in early times, is the fourth son of Nahor,[13] the brother of Abraham; and some have been of opinion that the Chaldeans were the progeny of this same Chesed. This appears to us highly probable, because both Abram and Nahor were[14] natives of Ur of the Chasidim. The former, we know, in consequence of the divine command, removed to Haran, afterwards *Charræ;* but the latter remained in Ur, where his family multiplied, and, in process of time, became masters of the country which they called the land of the Chasidim, from Chesed or Chased, the name of their ancestor. This account is the more probable, as we find the other branches of Nahor's family settled in the same neighbourhood.[15]

Origin of the name *Chaldæi.*

How the Greeks came to denominate these people Χαλδαιοι, *Chaldæi*, is a question rather difficult to be resolved; but we know that they always affected to distinguish people and places by names derived from their own language. They knew a rugged, erratic nation[16] on the banks of the Thermodoon, in the territory of Pontus, bordering on Armenia the Less. These, in ancient times, were called *Alybes* or *Calybes*, because they were much employed in forging and polishing iron. Their neighbours, at length, gave them the name of *Chald* or *Caled*, which imports, in the Armenian dialect, fierce, hardy, robust. This title the Greeks adopted, and out of it formed the word Χαλδαιοι, or Chaldeans.

The Mosaic history informs us,[17] that Ashur went out of the land of Shinar, and built Nineveh and several other considerable cities. One of the successors of Ashur was the celebrated Ninus, who first broke the peace of the world,[1] made war upon his neighbours, and obliged them by force of arms to become his subjects, and pay tribute. Some authors make him the immediate successor of Ashur, and the builder of Nineveh. This we think is not probable; and Eusebius, as we have observed above, gives a list of six Arabian princes who reigned in Babylon. These we take to have been the immediate successors of Nimrod, called *Arabians*, because these people were Cushites. Ninus might be reputed the first king of the Assyrians, because he figured beyond his predecessors; and he might pass for the builder of Nineveh, because he greatly enlarged and beautified that city. We therefore imagine, that Ninus was the fifth or sixth in succession after Ashur.

---

[1] This war was probably carried on between the leaders of the Hamites and Ashur upon their invasion.

[15] Huz gave name to the country of Job; Elihu, one of Job's friends, was a Buzite of the kindred of Ram or Aram, another of the sons of Nahor. Aram, whose posterity planted Syria Cava, was the grandson of Nahor by Kemuel. Hence it appears probable that Job himself was a descendant of Nahor by Huz his first born.

[16] See Eustat. *in Dion. Perieg.* v. 768. Strabo, lib. xii. p. 543. Casaub. As the Chalybes were famous for manufacturing iron, so were they celebrated for making the choicest pieces of armour. They excelled in making κλιϐανοι, or coats of mail, or brigandines, used by the bravest of the Persian horsemen. Bochart (*Phaleg.* lib. iii. cap. 12 and 13) has proved that the word *Cheliba* signifies "scales of brass or steel." From the word *Cheliba*, the Greeks formed their Χαλυϐεις, *Chalybes.* Xenophon (*Cyrop.* lib. iii. p. 43, Steph.) represents the Chaldeans, who inhabited a mountainous country bordering upon Armenia, as a very fierce and warlike people. In page 107, we have an example of their rapacious character; and in lib. iv. p. 192, Hen. Steph. we have an account of their bravery and of their arms. Another instance of their rapacity occurs in their plundering the cattle of Job.

[17] A dispute has arisen about the sense of verse 10, chap. x. "Out of that land went forth Ashur, and builded Nineveh." Some approve our translation, which we think is just; others, considering that the inspired writer had been speaking of Nimrod and the beginning of his kingdom, are of opinion that it should be translated, "And out of this land *He.* (that is Nimrod,) went into Ashur and builded Nineveh." This they make a military expedition, and a violent irruption into the territory of Ashur.

Ninus, according to Diodorus Siculus,[2] made an alliance with Ariæus king of the Arabians, and conquered the Babylonians. This event, in our opinion, put an end to the empire of the Hamites or Cushim in Shinar or Babylonia. The author observes, that the Babylon which figured afterwards did not then exist. This fact is confirmed by the prophet Isaiah:[3] "Behold the land of the Chasidim; this people was not till Ashur founded it for them that dwell in the wilderness. They set up the towers thereof," &c. After Babylonia was subdued by the Assyrians under Ninus, the capital was either destroyed by that conqueror or deserted by the inhabitants. At length it was re-built by some one or other of the Assyrian monarchs, who collected the roving Chasidim, and obliged them to settle in the new city. These were subject to the Assyrian empire till the reign of Sardanapalus, when both the Medes and Babylonians rebelled against that effeminate prince.

The Chasidim were celebrated by all antiquity for their proficiency in astronomy, astrology, magic, and curious sciences. Ur or Orchoe was a kind of university for those branches of learning.[4] Such was their reputation in those studies, that over a great part of Asia and Europe a Chaldean and an astrologer were synonymous terms. These sciences, according to the tradition of the Orientals, had been invented by Seth, whom they called *Edris*; and had been cultivated by his descendants downwards to Noah, by whom they were transmitted to Shem, who conveyed them to Arphaxad and his posterity. To us it appears probable, that the religious sentiments transmitted from Noah through the line of Shem, were kept alive in the family of Arphaxad, and so handed down to the families of Serug, Nahor, Terah, Abraham, Nahor II. and Haran, &c. The Jewish rabbin, and all the Persian and Mahommedan writers, make Abraham contemporary with Nimrod; who, say they, persecuted him most cruelly for adhering to the true religion. That these two patriarchs were contemporary is very improbable, since Nimrod was the third generation after Noah, and Abraham the tenth. Abraham has been invested by the rabbinical writers with every department of learning. According to them, he transported from Charræ into Chanaan, astronomy, astrology, mathematics, geography, magic, alphabetical writing, &c.

gendary es concerning oraham.

After the Babylonish captivity, when the Jews were dispersed over all the east, and began to make *proselytes of the gate* amongst the Pagans, wonderful things were reported of Abraham with respect to his acquirements in human erudition, as well as his supereminence in virtue and piety. These legendary tales were believed by the proselytes, and by them retailed to their connections and acquaintances. But certainly the holy man was either not deeply versed in human sciences, or he did not deem them of importance enough to be communicated to his posterity; since the Jews are, on all hands, acknowledged to have made little progress in these improvements. To think of raising the fame of Abraham, by classing him with the philosophers, betrays an extreme defect in judgment. He is entitled to praise of a higher kind; for he excelled in piety, was the father of the faithful, the root of the Messiah, and the friend of God. Before these, all other titles vanish away. Such of our readers, however, as have leisure enough, and at the same time learning enough to enable them to consult the rabbinical legends, will be furnished with a full and ample detail of his imaginary exploits and adventures. Others, who are either not willing or not qualified to peruse the writings of the rabbin, may consult Dr. Hyde[5] and the authors of the Universal History,[6] where they will find materials sufficient to gratify their curiosity. We shall only observe, in addition to what we have already said, that the Persians, Chaldeans, and Arabians, pretended that their religion was that of Abraham; that honourable mention is made of him in the Koran; and that the name of Abraham or Ibrahim was celebrated all over the east.

In the progress of this disquisition, we have seen that the language of Noah was, in all probability, the same or nearly the same with that of Adam. Additions and improvements might be introduced, but still the radical stamina of the language remained unchanged. It has likewise, we hope, appeared, that the confusion of language at the building of the tower of Babel was only partial, and affected none but the rebellious crew of the race of Ham, and the apostate part of the families of Shem and Japhet. We have concluded, that the main body of the race of Shem, at least, were not dispersed nor was their language confounded; and that consequently the descendants of that patriarch continued to speak their paternal dialect or the uncorrupted language of Noah. To these arguments we may take the liberty to add another, which is, that in all probability the worship of the true God was preserved in the line of Arphaxad, after the generality of the other sects had lapsed into idolatry. Out of this family was taken Abraham, in whose line the true religion was to be preserved. Whether Abraham was an idolater when he dwelt in Chaldæa, the Scripture does not inform us, though it seems to be evident that his father was. One thing, however, is certain, namely, that Jehovah appeared to him, and pronounced a blessing upon him before he left Ur of the Chaldees.[7] This circumstance no doubt indicates, that the patriarch had made uncommon advances in piety and virtue, even prior to his emigration. The progenitors of his family had been distinguished by adhering to the true religion. About this time, however, they began to degenerate, and to adopt the Zabaism of their apostate neighbours. It was then that Abraham was commanded by Heaven to "leave his kindred and his father's house, and to travel into a land which was to be shown him." The Almighty intended that the true religion should be preserved in his line, and therefore removed him from a country and kindred, by the influence of whose bad example his religious principles might be endangered. His family had only of late apostatized; until that period they had preserved both the language and the religion of their venerable ancestors.

But however much Abraham might differ from the other

---

[4] Ur or Orchoe was situated between Nisibis and Corduena. (See Ammianus Marcellinus, *Expeditio Juliana*, lib. xv.) It lay not far from the river Tigris. Strabo, (lib. xvi. p. 739.) tells us that the Chaldean philosophers were divided into different sects; the Orcheni, the Borsipenni, and several others. Diodorus Siculus likewise, (lib. ii. p. 82. Steph.) gives an exact detail of the functions, profession, and establishment of the Chaldeans, to which we must refer our curious readers.

[5] *De Religione Veterum Persarum*, chap. ii. [6] Vol. i.

[7] Compare Gen. xii. 2 with Acts vii. 4.

The Hebrew and Chaldaic originally the same.

branches of his family in his religious sentiments, his language was certainly in unison with theirs. The consequence of this unquestionable position is, that the language which he carried with him into Chanaan was exactly the same with that of his family which he relinquished when he began his peregrinations. But if this be true, it will follow, that the language afterwards denominated Hebrew, and that of the Chasidim or Chaldeans, were originally one and the same. This position, we think, will not be controverted. There is then an end of the dispute concerning the original language of mankind. We have advanced some presumptive proofs in the preceding pages, that the language of Adam was transmitted to Noah, and that the dialect of the latter was preserved in the line of Arphaxad downwards to the family of Abraham; and it now appears that the Hebrew and Chaldaic were originally spoken by the same family, and of course essentially indentical, and were actually the first language upon earth, according to the Mosaic history. Numberless additions, alterations, improvements, we acknowledge, were introduced in the course of two thousand years; but still the original stamina of the language were unchanged. Our readers will please to observe that the Orientals are not a people given to change; and that this character, in the earliest ages, was still more prevalent than at present. This assertion, we presume, needs no proof.

In confirmation of these presumptive arguments, we may add the popular one which is commonly urged upon this occasion, namely, that the names of antediluvian persons and places mentioned by the sacred historian, are generally of Hebrew original, and significant in that language. Some of them, we acknowledge, are not so; but in this case it ought to be remembered, that a very small part of that language now exists, and that probably the radicals from which these words are descended are amongst the number of those which have long been lost.

SECT. I. THE HEBREW LANGUAGE.

Characteristics of the Hebrew language.

Having thus proved the priority of the Hebrew to every other language that has been spoken by men, we shall now proceed to consider its nature and genius; from which it will appear still more evidently to be an original language, neither improved nor debased by foreign idioms. The words of which it is composed are short, and admit of very little flexion. The names of places are descriptive of their nature, situation, accidental circumstances, &c. Its compounds are few, and inartificially joined together. In it we find few of those artificial affixes which distinguish the other cognate dialects; such as the Chaldean, Syrian, Arabian, and Phœnician. We find in it no traces of improvement from the age of Moses to the era of the Babylonian captivity. The age of David and Solomon was the golden period of the Hebrew tongue; and yet, in our opinion, it would puzzle a critic of the nicest acumen to discover much improvement even during that happy era. In fact, the Jews were by no means an inventive people. We hear nothing of their progress in literary pursuits; nor do they appear to have been industrious in borrowing from their neighbours. The laws and statutes communicated by Moses were the principal objects of their studies. These they were commanded to contemplate day and night; and in these they were to place their chief delight. The consequence of this command was, that little or no regard could be paid to taste, or any other subject of philosophical investigation. Every unimproved language abounds in figurative expressions borrowed from sensible objects. This is in a peculiar manner the characteristic of the language in question; of which it would be superfluous to produce instances, as the fact must be obvious even to the attentive reader of the English Bible.

In the course of this argument, we think it ought to be observed, and we deem it an observation of the greatest importance, that if we compare the other languages which have claimed the prize of originality from the Hebrew with that dialect, we shall quickly be convinced that the latter has a just title to the preference. The writers who have treated this subject, generally bring into competition the Hebrew, Chaldean, Syrian, and Arabian; and some one or other of these has commonly been thought the original language of mankind. The arguments for the Syrian and Arabian are altogether futile. The numerous improvements superinduced upon these languages, evidently prove that they could not have been the original language. In all cognate dialects, etymologists hold it as a maxim, that the least improved is likely to be the most ancient.

How it was cha ed into what is called th Chaldaic.

We have observed above, that the language of Abraham and that of the Chesedim or Chaldeans were originally the same; and we are persuaded, that if an able critic should take the pains to examine strictly these two languages, and to take from each what may reasonably be supposed to have been improvements or additions since the age of Abraham, he would find intrinsic evidence sufficient to convince him of the truth of this position. There appear still in the Chaldean tongue great numbers of words the same with the Hebrew,[1] perhaps as many as mankind had occasion for in the most early ages; and much greater numbers would probably be found if both languages had come down to us entire. The construction of the two languages is indeed somewhat different; but this difference arises chiefly from the superior improvement of the Chaldean. Whilst the Hebrew language was in a manner stationary, the Chaldean underwent progressive improvements; was mellowed by antitheses, rendered sonorous by the disposition of vocal sounds, and acquired a copiousness by compounds, and a majesty by affixes and prefixes. In process of time, however, the difference became so great, that the Israelites did not understand the Chaldean language at the era of the Babylonish captivity. This much the prophet intimates,[2] when he promises the pious Jews protection "from a fierce people; a people of a deeper speech than they could perceive; of a stammering tongue, that they could not understand."

The priority of the Chaldean tongue is indeed contended for by very learned writers. Camden calls it the mother of all languages;[3] and most of the Fathers were of the same opinion. Amira[4] has made a collection of arguments, not inconsiderable in favour of it; and Myriceus[5] after him, did the same. Erpenius,[6] in his Oration on the Hebrew tongue, thought the argument for it and the Chaldean so equal, that he did not choose to take upon him to determine the question.

Reasons for maintaining t priority the Hebrew.

Many circumstances, however, concur to make us assign the priority to the Hebrew, or rather to make us believe that it has suffered fewest of those changes to which every living tongue is more or less liable. If we strip this language of every thing obviously adventitious, we shall find it extremely simple and primitive. 1. Every thing masoretical, supposing the vowels and points essential,[7] was certainly unknown in its original character. 2. All the prefixed and affixed letters were added time after time, to give more compass and precision to the language. 3. The various voices, moods, tenses, numbers, and persons of verbs, were posterior improvements; for in that tongue, nothing at first appeared but the indeclinable radix. 4. In the same manner, the few adjectives which occur in the language, and the numbers and regimen of nouns, were not from the beginning. 5. Most of the Hebrew nouns are derived from verbs, indeed many of them are written with the very same letters. This rule, however, is not general; for verbs are often derived from nouns, and even some from prepositions. 6. All the verbs of that language, at least all that originally belonged to it, uniformly consist of three letters, and seem to have been at first pronounced as monosyllables. If we anatomize the Hebrew language in this manner, we shall reduce it to very great simplicity; we shall confine it to a few names of things, persons, and actions; we shall make all its words monosyllables, and give it the true characters of an original language. If at the same time we reflect on the small number of radical words in that dialect,[1] we shall be more and more convinced of its originality.

---

[1] Most of the Chaldean names mentioned in Scripture are pure Hebrew words compounded; such as *Nebuchadnezzar, Nebuzuradan, Rabshakeh, Rabmag, Belshazzar, Rabsaris, Nahar, Malahtha, Phrat* or *Pharad, Barosus, Carchemish, Ur, Cutha,* Heb. *Cush,* &c. All these words, and a multitude of others which we could mention, approach so near the Hebrew dialect, that their original is discernible at first sight. Most of these are compounds, which the limits prescribed us will not allow us to analyse and explain.

[3] *Brit.*

[4] *Præf. ad Gram. Syr.*

[5] *Præf. ad Gram. Chald.*

[6] *Oratio de Lingua Hebr.* xii.

[7] The futility of these points will be proved in the following part of this section.

It will not be expected that we should enter into a minute discussion of the grammatical peculiarities of this ancient language. For these we must refer our readers to the numerous and elaborate grammars of that tongue, which are everywhere easily to be found. We shall only make a few strictures, which naturally present themselves, before we dismiss the subject.

. lan- ges in t east o inally t same.

The generality of writers who have maintained the superior antiquity of the Hebrew language, have at the same time contended that all other languages of Asia, and most of those of Europe, have been derived from that tongue as their source and matrix. For our own part we are of opinion, that perhaps all the languages in the eastern part of the globe were coeval with it, and were originally one and the same; and that the differences which afterwards distinguished them sprung from climate, caprice, inventions, religions, commerce, conquests, and other accidental causes, which will occur to our intelligent readers. We have endeavoured to prove, in the preceding pages, that all mankind were not concerned in the building of the fatal tower, nor affected by the punishment consequent upon that attempt; and we now add, that even that punishment was only temporary, since we find, that those very Hamites or Cushim, who are allowed to have been affected by it, did certainly afterwards recover the former organization of their tongue, and differed not more from the original standard than the descendants of Japhet and Shem.

The Jewish rabbin have pretended to ascertain the number of languages generated by the vengeance of Heaven at the building of Babel. They tell us that mankind was divided into seventy nations and seventy languages, and that each of these nations had its tutelar or guardian angel. This fabulous legend is founded on the number of the progeny of Jacob at the time when that patriarch and his family went down into Egypt. Others attribute its origin to the number of the sons and grandsons of Noah, who are enumerated in Genesis.

The Fathers[2] of the church make the languages at the confusion amount to seventy-two; which number they complete by adding Cainan and Elishah, according to the Septuagint, who are not mentioned in the Hebrew text. This opinion, they conceive, is supported by the words of Moses, where he says,[3] that "when the Most High divided to the nations their inheritance, when he separated the sons of Adam, he set the bounds of the people according to the number of the tribes of Israel." That is, say they, he divided them into seventy-two nations, which was the number of the children of Israel when they came into Egypt. The Targum of Ben-Uzziel plainly favours this interpretation; but the Jerusalem Targum intimates that the number of nations was only twelve, according to the number of the tribes of Israel. This passage, however, seems to refer to the tribes of the Chanaanim, and imports, that the Almighty assigned to the different septs of that family such a tract of land as he knew would make a sufficient inheritance for the children of Israel.[4] Others have increased the different languages of the dispersion to a hundred and twenty; but the general opinion has fixed them at seventy or seventy-two. Our readers need scarcely be put in mind that these opinions are futile and absurd, being founded neither in Scripture, profane history, nor common sense. At the same time, it must not be omitted, that according to Horus Apollo,[5] the Egyptians held, that the world was divided into seventy-two habitable regions; and that, in consequence of this tradition, they made the cynocephalus the emblem of the world, because that in the space of seventy-two days that animal pines away and dies.

Origin of the name *Hebrew.*

It has been made a question, whether the Hebrew language was denominated from Heber the progenitor of Abraham, or from a word which in that tongue imports *over, beyond.* Most of the Christian fathers, prior to St. Origen, believed that both the Gentile name *Hebrew,* and the name of the language, were derived from the name of the patriarch; but that learned man imagined, that Abraham was called the *Hebrew,* not because he was a descendant of Heber, but because he was a *transfluvianus,* or from beyond the river Euphrates. The learned Bochart[6] has strained hard to prove the former position; but to us his arguments do not appear decisive. We are rather inclined to believe, that Abraham was called *Chibri,* or Hebrew, from the situation of the country whence he emigrated when he came to the country of Chanaan; and that in process of time that word became a Gentile appellation, and was afterwards applied to his posterity often by way of reproach,[7] much in the same manner as we say a Northlander, a Norman, a Tramontane, and the like.

Here we may be indulged an observation, namely, that Abraham, a Hebrew, lived amongst the Chaldeans, travelled amongst the Chanaanites, sojourned amongst the Philistines, lived some time in Egypt, and in all appearance conversed with all those nations without any apparent difficulty. This circumstance plainly proves, that all these nations at that time spoke nearly the same language. The nations had not yet begun to improve their respective dialects, nor to deviate in any great measure from the monosyllablic idiom of the Hebrews. With respect to the language of Chanaan, afterwards the Phœnician, its similarity to the Hebrew is obvious from the names of gods, men, cities, mountains, rivers, and the like, which are the very same in both tongues, as might be shown in numberless cases, were this a proper place for etymological researches.

Before we dismiss this part of our subject, we would wish to gratify our unlearned readers with a brief account of the the Hebrew letters, and of the Masoretical points which have in a manner been ingrafted on these letters. In the course of this deduction, we shall endeavour to follow such authors as are allowed to have handled that matter with the greatest acuteness, learning, and perspicuity. If upon any occasion, we should be tempted to hazard a conjecture of our own, it is cheerfully submitted to the candour of the public.

---

Origin of alphabetic writing.

Much has been written, and numberless hypotheses proposed, with a view to investigate the origin of alphabetical writing. To give even an abridged account of all these, would fill many volumes. The most plausible, in our opinion, is that which supposes that the primary characters employed by men were the figures of material objects, analogous to those of the Mexicans, so often mentioned by the authors who have written the history of that people at the era of the Spanish invasion of their country. As this plan was too much circumscribed to be generally useful, hieroglyphical figures were in process of time invented as subsidiaries to this contracted orthography. In this scheme, we imagine, the process was somewhat more extensive. A lion might be sketched, to import fierceness or valour; an ox, to denote strength; a stag, to signify swiftness; a hare, to intimate timorousness, &c.

The next step in this process would naturally extend to the inventing and appropriating of a few arbitrary characters, for representing abstract ideas, and other relations, which could not be well ascertained by the methods above mentioned. These arbitrary signs might readily acquire a currency by compact, as money and medals do over a great part of the world. Upon this plan we imagine the ancient Chinese formed their language.

But neither the picture nor the hieroglyphic, nor the method of denoting ideas by arbitrary characters appropriated by compact, could ever have arrived at such perfection as to answer all the purposes of ideal communication. The grand desideratum then would be to fabricate characters to represent simple sounds, and to reduce these characters to so small a number as to be easily learned and preserved in the memory. In this attempt the Chinese have notoriously failed; their letters, or rather their characters, are so numerous, that few, if any, of their most learned and industrious authors, have been able to learn and retain the whole catalogue. Indeed those people are not able to conceive how any combinations of twenty or thirty characters should be competent to answer all the purposes of written language.

Many different nations have claimed the honour of this invention. The Greeks ascribed it to the Phœnicians, and used the word φοινεκιζειν,[1] *to act the Phœnician*, in the same sense with ἀναγινωσκειν, *to read;* and consequently the poet[2] ascribes the invention to the same ingenious people. The Greeks borrowed their letters from the Phœnicians, and of course looked up to them as the inventors.

Others have attributed the invention to the Egyptians. That people ascribed every useful and ingenious invention to their Thoth, or Mercury Trismegistus. Plato seems to have believed this tradition,[3] and pretends to record a dispute between the king of Egypt who then reigned and this personage, with respect to the influence which the art of alphabetic writing might possibly have upon the improvements of mankind in science and the liberal arts. Diodorus the Sicilian[4] gives a similar history of the same invention, but carries it back to the reign of Osiris.

Pliny informs us,[5] that Gellius attributed letters to the same Egyptian Mercury, and others to the Syrians; but that for "his part, he thought that the Assyrian letters were eternal." That learned Roman, then, imagined, that the Assyrian letters had existed at a period prior to all the records of history, which in fact was the case. By the Assyrian letters, he must mean the Chaldaic, and by the Syrian probably the Hebrew. The earliest Greek historians generally confound the Jews with the Syrians. Herodotus, enumerating the people who had learned circumcision from the Egyptians, mentions the Syrians of Palestine;[6] and elsewhere he tells us, that Necho beat the Syrians, and took Cadytis, a large and populous city belonging to that people.[7] Hence it is evident that the Syrian alphabet, or the Syrian letters, were the same with the Hebrew. That the Assyrian or Chaldaic and Hebrew languages were the same, has, we conceive, been fully proved already; that their letters were the same in the original structure, can scarcely be controverted.

Antedi vian.

These letters were, we think, antediluvian; whether, to use the expression of Plato, they were dictated by some god, or fabricated by some man divinely inspired. As this opinion may admit some dispute, we shall take the liberty to subjoin our reasons for entertaining it.

1. It appears that the era of this invention is involved in impenetrable obscurity. Had an invention of such capital importance to mankind been made in the postdiluvian ages, we imagine the author would have been commemorated in the historical annals of the country where he lived.[8]

2. The art of writing in alphabetical characters, according to the sacred records, was practised at so early a period, that there was not a long enough interval between that and the deluge to give birth to this noble invention. If we consider the state of the world during some ages after that disastrous event, we shall quickly be convinced that little respite could be found from the labour and industry indispensably requisite to provide the necessaries, and only a few of the conveniencies of life. Such a state of things was certainly most unfavourable to the invention of those arts and improvements which contribute nothing towards procuring the accommodations of life. The consequence is obvious.

Moses has recorded the history of the creation, and a few of the capital transactions of the antediluvian world, the birth, the age, the death, of the lineal descendants of Seth. He has preserved the dimensions of the ark, the duration of the universal deluge, its effects upon man and all terrestrial animals, the population of the world by the posterity of Noah, the age, &c. of the patriarchs of the line of Shem, from which his own ancestors had sprung. To this he has subjoined the petty occurrences which diversified the lives of Abraham, and Isaac, and Jacob, and their descendants. Whence did the historian derive his information? We believe few of our readers will be so enthusiastic as to imagine that the author received it from divine inspiration. Tradition is a fallible guide; and in many cases the accounts are so minutely precise, as to defy the power of that species of conveyance. The inspired author must certainly have extracted his abridgment from written memoirs, or histories of the transactions of his ancestors regularly transmitted from the most early periods. These annals he probably abridged, as Ezra did afterwards the history of the kings of Israel. Supposing this to be the case, as it most certainly was, the art of writing in alphabetical letters must have been known and practised many ages before Moses. It has indeed been pretended, that the Jewish decalogue, inscribed upon two tables of stone, was the very first specimen of alphabetical writing. But the arguments produced in proof of this notion are lame and inconclusive.[9] Had that been the case, some notice must have been taken of so palpable a circumstance. Moses wrote out his history, his laws, and his memoirs; and it appears plainly from the text, that all the learned amongst his countrymen could read them. Writing was then no novel invention in the age of the Jewish legislator, but current and generally known at that era.

[8] It is true, the Egyptians attribute the invention to their Thoth, and the Phœnicians to their Hercules, or Melicerta or Baal; but these were only imaginary personages.

[9] The most ingenious and plausible of those arguments which have fallen under our observation, is given by Mr. Johnson, vicar of Cranbrook, a writer of great learning and piety, who flourished in the beginning of the eighteenth century, and whose works deserve to be more generally known than we have reason to think they are. After endeavouring to prove that alphabetical writing was not practised before the era of Moses, and expatiating upon the difficulty of the invention, this excellent scholar attempts to show, that the original Hebrew

The patriarch Job lived at an earlier period. In the book of the same name we find many allusions to the art of writing, and some passages which plainly prove its existence. This shews that alphabetical characters were not confined to the chosen seed, since Job was in all probability a descendant of Huz, the eldest son of Nahor,[1] the brother of Abraham. From this circumstance, we think we may fairly conclude, that the art of writing was known and practised in the family of Terah the father of Abraham.

radition specting ting.

3. There was certainly a tradition amongst the Jews in the age of Josephus, that writing was an antediluvian invention.[2] That historian pretends, that the descendants of Seth erected two pillars, the one of stone and the other of brick, and inscribed upon them their astronomical observations and other improvements. This legend shows that there did exist such an opinion in regard to the antiquity of the art of writing.

4. There must have been a tradition to the same purpose amongst the Chaldeans, since the writers who have copied from Berosus, the celebrated Chaldean historian,[3] speak of alphabetical writing as an art well known amongst the antediluvians. According to them, Oannes the Chaldean legislator gave his disciples an insight into letters and science. This person also *wrote* concerning the generation of mankind, of their different pursuits, of civil polity, and other matters. Immediately before the deluge, say they, the god Kronos appeared to Sisuthrus or Xisuthrus, and commanded him to commit to writing the beginning, improvement, and conclusion of all things down to the present time, and to bury these accounts securely in the temple of the Sun at Seppara. All these traditions may be deemed fabulous in the main; but still they evince that such an opinion was current, and that although the use of letters was not indeed eternal,[4] it was, however, prior to all the records of history; and of course, we think, an antediluvian discovery.

The original alphabet preserved in the family of Noah.

This original alphabet, whatever it was, and however constructed, was, we think, preserved in the family of Noah, and from it conveyed down to succeeding generations. If we can then discover the original Hebrew alphabet, we shall be able to investigate the primary species of letters expressive of those articulate sounds by which man is in a great measure distinguished from the brute creation. Whatever might be the nature of that alphabet, we may be convinced that the ancient Jews deemed it sacred, and therefore preserved it pure and unmixed until the Babylonian captivity. If, then, any monuments are still extant inscribed with letters prior to that event, we may rest assured that these are the remains of the original alphabet.

The same with the Samaritan.

There have, from time to time, been dug up at Jerusalem, and other parts of Judea, coins and medals, and medallions, inscribed with letters of a form very different from those square letters in which the Hebrew Scriptures are now written. When the Samaritan Pentateuch was discovered,[5] it evidently appeared that the inscriptions on those medals and coins were drawn in genuine Samaritan characters. The learned Abbé Barthélèmi, in his disser-

---

alphabet was actually communicated to the Jewish legislator at the same time with the two tables of the law. "I know not," says he, "any just cause why the law should be *written by God*, or by *an angel* at his command, except it were for want of a man that could well perform this part. This could give no addition of authority to the law, especially after it had been published in that astonishing and miraculous manner at Mount Sinai. The true writing of the original was indeed perfectly adjusted, and precisely ascertained to all future ages, by God's giving a copy of it under his own hand; but this, I conceive, had been done altogether as effectually by God's dictating every word to Moses, had he been capable of performing the office of an amanuensis." The learned writer goes on to suppose, that it was for the purpose of teaching Moses the alphabet, that God detained him forty days in the Mount; and thence he concludes, that the Decalogue was the first writing in alphabetical characters, and that these characters were a divine, and not a human invention.

It is always rash, if not something worse, to conceive reasons not assigned by God himself, for any particular transaction of his with those men whom he from time to time inspired with heavenly wisdom. That it was *not* for the purpose of teaching Moses the alphabet that God detained him forty days in the Mount, when he gave him the two tables of the law, seems evident from his detaining him just as many days when he gave him the second tables after the first were broken. If the legislator of the Jews had not been sufficiently instructed in the art of reading during his first stay in the Mount, he would have been detained longer; and it is not conceivable, that though in a fit of pious passion he was so far thrown off his guard as to break the two tables, his mind was so totally unhinged by the idolatry of his countrymen, as to forget completely an art which, by the supposition, the Supreme Being had spent *forty days* in teaching him. "But if Moses could, at his first ascent into the Mount, perform the office of an amanuensis, why are the original tables said to have been written by the finger of God, and not by him who wrote the second?" We pretend not to say why they were written by God rather than man; but we think there is sufficient evidence, that by whomsoever they were written, the characters employed were of human invention. The Hebrew alphabet, without the Masoretic points, is confessedly defective; and every man who is in any degree acquainted with the language, and is not under the influence of inveterate prejudice, will readily admit that those points are no improvement. But we cannot, without impiety, suppose an art invented by infinite wisdom, to fall short of the utmost perfection of which it is capable. An alphabet communicated to man by God, would undoubtedly have been free both from defects and from redundancies; it would have had a distinct character for every simple sound, and been at least as perfect as the Greek or the Roman.

But we need not fill our pages with reasonings of this kind against the hypothesis maintained by Mr. Johnson. We know that "Moses wrote all the words of the Lord," that is, the substance of all that had been delivered, in Exod. xx, xxi, xxii, xxiii, before he was called up into the Mount to receive the tables of stone; nay, that he had long before been commanded by God himself, to "write in a book" an account of the victory obtained over Amalek, (Exod. xvii. 14.) All this, indeed, the learned writer was aware of; and to reconcile it with his hypothesis, he frames another, more improbable than even that which it is meant to support. "It is not unreasonable," says he, "to believe that God had written these tables of stone, and put them in Mount Horeb, from the time that by his angel he had there first appeared to Moses; and that, therefore, all the time after, whilst he kept Jethro's sheep thereabouts, he had free access to those tables, and perused them at discretion." But if belief should rest upon evidence, we beg leave to reply, that to believe all this would be in the highest degree unreasonable; for there is not a single hint in the Scripture of the tables having been written at so early a period, or upon such an occasion, as God's first appearance to Moses in the burning bush. We know how reluctant Moses was to go upon the embassy to which he was then appointed; and it is strange, we think passing strange, that when he records so faithfully his own backwardness, and the means made use of by God to reconcile him to the arduous undertaking, he should make no mention of these important tables, if at that period he had known any thing of their existence. Besides all this, is it not wonderful, that, if Moses had been practising the art of writing, as our author supposes, from the time of the burning bush to the giving of the law, he should then have stood in need of forty days teaching from God, to enable him to read with ease the first tables, and of other forty, to enable him to write the second? This gives such a mean view of the natural capacity of the Hebrew legislator, as renders the hypothesis which implies it wholly incredible. (See a *Collection of Discourses*, in two vols. by the Rev. John Johnson, vicar of Cranbrook in Kent.)

[5] The celebrated Archbishop Usher was the first who brought the Samaritan Pentateuch into Europe. In a letter to Ludovicus Capellus "he acknowledges, that the frequent mention he had seen made of it by some authors, would not suffer him to be at rest till he had procured five or six copies of it from Palestine and Syria."

tation[1] "on the two medals of Antigonus, king of Judea, one of the later Asmonean princes, proves that all the inscriptions on the coins and medals of Jonathan and Simon Maccabeus, and also on his, were invariably in the Samaritan character down to the fortieth year before the Christian era."

This afterwards gave place to the Chaldaic.

It were very easy to prove, from the Misna and Jerusalem Talmud, that the Scriptures publicly read in the synagogues to the end of the second century were written in the Samaritan character, we mean in the same character with the Pentateuch in question. As the ancient Hebrew, however, ceased to be the vulgar language of the Jews after the return from the Babylonian captivity, the copies of the Bible, especially in private hands, were accompanied with a Chaldaic paraphrase; and at length the original Hebrew character fell into disuse, and the Chaldaic was universally adopted.

It now appears that the letters inscribed upon the ancient coins and medals of the Jews, were written in the Samaritan form, and that the Scriptures were written in the very same characters. We shall therefore leave it to our readers to judge whether, considering the implacable hatred which subsisted between these two nations, it be likely that the one copied from the other; or at least that the Jews preferred to the beautiful letters used by their ancestors, the rude and inelegant characters of their most detested rivals. If, then, the inscriptions on the coins and medals were actually in the characters of the Samaritan Pentateuch (and it is absurd to suppose that the Jews borrowed them from the Samaritans,) the consequence plainly is, that the letters of the inscriptions were those of the original Hebrew alphabet, coeval with that language, which we venture to maintain was the first upon earth.

It may, perhaps, be thought rather superfluous to mention, that the Samaritan colonists, whom the kings of Assyria planted in the cities of Samaria,[2] were natives of countries where the Chaldaic letters were current, and who were probably ignorant of the Hebrew language and characters. When those colonists embraced the Jewish religion, they procured a copy of the Hebrew Pentateuch written in its native character, which, from superstition, they preserved inviolate as they received it; and from it were successively copied the others which were current in Syria and Palestine when Archbishop Usher procured his.

From the reasons above explained, then, we hope it will be obvious, that if the Hebrew alphabet, as it appears in the Samaritan Pentateuch, was not the primitive one, it was at least that in which the Holy Scriptures were first committed to writing.

The Chaldaic introduced by Ezra.

Scaliger has inferred, from a passage in Eusebius,[3] and another in St. Jerome,[4] that Ezra, when he reformed the Jewish church, transcribed the Scriptures from the ancient characters of the Hebrews into the square letters of the Chaldeans. This, he thinks, was done for the use of those Jews who, being born during the captivity, knew no other alphabet than that of the people amongst whom they had been educated. This account of the matter, though probable in itself, and supported by passages from both Talmuds, has been attacked by Buxtorf with great learning and no less acrimony. Scaliger, however, has been followed by a crowd of learned men,[5] whose opinion is now pretty generally espoused by the sacred critics.

Having said so much concerning the Hebrew alphabet in the preceding pages, we find ourselves laid under a kind of necessity of hazarding a few strictures on the vowels and Masoretic points; the *first* essential to, and the *last* an appendage of, that ancient language. The number of the one, and the nature, antiquity, and necessity of the other, in order to read the language with propriety and with discrimination, have been the subject of much and often illiberal controversy amongst philological writers. To enter into a minute detail of the arguments on either side, would require a complete volume. We shall, therefore, briefly exhibit the state of the controversy, and then venture a few observations, which, in our opinion, ought to determine the question.

The H brew v els.

The controversy then is, whether the Hebrews used any vowels, or whether the points, which are now called by that name, were substituted instead of them? or if they were, whether they be as old as the time of Moses, or were invented by Ezra, or by the Masorites?[6] This controversy has exercised the ingenuity of the most learned critics of the two last centuries, and is still far enough from being determined in the present. The Jews maintain, that these vowel points[7] were delivered to Moses along with the tables of the law, and consequently hold them as sacred as they do the letters themselves. Many Christian authors who have handled this subject, although they do not affirm their divine original, nor the extravagant antiquity of these points, pretend, however, that they are the only proper vowels in the language, and regulate and ascertain its true pronunciation. Though they differ from the Jews with respect to the origin of these points, they yet allow to them a pretty high antiquity, generally ascribing them to Ezra and the members of the great synagogue.

The M retic p a moder inventio

At length, however, about the middle of the sixteenth century, Elias Levita, a learned German Jew, who then flourished at Rome, discovered the delusion, and made it appear that these appendages had never been in use till after the writing of the Talmuds, about five hundred years after Christ. This innovation raised Elias a multitude of adversaries, both of his own countrymen and Christians. Amongst the latter appeared the two Buxtorfs, the father and the son, who produced some cabbalistical books of great antiquity,[8] at least in the opinion of the Jews, in which mention was expressly made of the points. The Buxtorfs were answered by Capellus and other critics,[9] till Father Morinus,[10] having examined all that had been urged on both sides, produced his learned dissertation on that subject; against which there has been nothing replied of any consequence, whilst his work has been universally admired, and his opinion confirmed by those that have beaten the same field after him.

According to this learned father, it plainly appears that neither Origen, nor St. Jerome, nor even the compilers of the Talmuds, knew any thing of what has been called the vowel points; and yet these books, according to the same author, were not finished till the seventh century. Even the Jewish rabbin who wrote during the eighth and ninth centuries, were not, according to him, in the least acquainted with these points. He adds, that the first vestiges he could trace of them were in the writings of Rabbi Ben Aber chief of the western, and of Rabbi Ben Naphtali, chief of the eastern school, that is, about the middle of the tenth century; so that they can hardly be said to be older than the beginning of that period.

---

[1] *Mémoires de l'Académie des Inscript.*

[2] 2 Kings xvii. 24. "And the king of Assyria brought men from Babylon, and from Cuthah, and from Avah, and from Hamath, and from Sepharvaim, and placed them in the cities of Samaria." Babylon and Cuthah, and Avah, were neighbouring cities, and undoubtedly both spoke and wrote in the Chaldaic style. The natives of Hamath spoke the Syriac, which at that time differed very little from the Chaldaic.

[5] Casaubon, Grotius, Vossius, Bochart, Morin, Brerewood, Walton, Prideaux, Huet, and Lewis Capel, always a sworn enemy to Buxtorf. All these have maintained the same ground with Scaliger; how truly, appears above.

[6] The term *masorah* or *massoreth* signifies "tradition," and imports the unwritten canon by which the reading and writing of the sacred books was fixed.

[7] These points are fourteen in number, and their figures, names, and effects, may be seen in most Hebrew Grammars.

[8] These books are the *Bahir*, *Zahar*, and the *Kizri*. As for the Kizri, the Jews make it about nineteen hundred years old; and the other about a century later. But the fidelity of the Jews in such matters cannot be relied upon.

[9] Walton, Dupin, and Vossius.

[10] *Dissertation sur la Bible.*

Some learned men[1] have ascribed the invention of the vowel points in question to the rabbin of the school of Tiberias; which, according to them, flourished about the middle of the second century. This opinion is by no means probable, because it appears plain from history, that before that period all the Jewish seminaries in that province were destroyed, and their heads forced into exile. Some of these had retired into Babylonia, and settled at Sora, Naherds, and Pombeditha, where they established famous universities. After this era, there remained no more any rabbinical schools in Judea, headed by professors capable of undertaking this difficult operation, nor indeed of sufficient authority to recommend it to general practice, had they been ever so thoroughly qualified for executing it.

The *matres ectionis.*

Capellus and Father Morin, who contend for the late introduction of the vowel-points, acknowledge that there can certainly be no language without vocal sounds, which are indeed the soul and essence of speech; but they affirm that the Hebrew alphabet actually contains vowel characters, as well as the Greek and the Latin, and the alphabets of modern Europe. These are *aleph, he, vau, jod,* which they call the *matres lectionis,* or, if you please, the parents of reading, and to which some, we think very properly, add *ain* or *oin, ajin.* These, they conclude, perform exactly the same office in Hebrew that their descendants do in Greek. It is indeed agreed, upon all hands, that the Greek alphabet is derived from the Phœnician, which is known to be the same with the Samaritan or Hebrew. This position we shall prove more fully when we come to trace the origin of the Greek tongue. Hitherto the analogy is not only plausible, but the resemblance is precise. The Hebrews and Samaritans employed these vowels exactly in the same manner with the Greeks; and so all was easy and natural.

bjections swered.

But the assertors of the Masoretic system maintain that the letters mentioned above are not vowels but consonants or aspirations, or any thing you please except vocal letters. This they endeavour to prove from their use amongst the Arabians, Persians, and other oriental nations. But to us it appears abundantly strange to suppose that the Greeks pronounced *beta, gamma, delta,* &c. exactly as the Hebrews and the Phœnicians did, and yet at the same time did not adopt their mode of pronunciation with respect to the five letters under consideration. To this argument we think every objection must undoubtedly yield. The Greeks borrowed their letters from the Phœnicians; and these letters were the Hebrew or Samaritan. The Greeks wrote and pronounced all the other letters of their alphabet, except the five in question, in the same manner with their originals of the east;[2] and if they did so, it obviously follows that the Greek and oriental office of these letters was the same.

Another objection made to reading the Hebrew without the aid of the Masoretic vowel points, arises from the consideration, that without these there will be a great number of radical Hebrew words, both nouns and verbs, without any vowel intervening amongst the consonants, which is certainly absurd. But notwithstanding this supposed absurdity, it is a well known fact, that all the copies of the Hebrew Scriptures, used in the Jewish synagogues throughout the world, are written or printed without points. These copies are deemed sacred, and kept in a coffer with the greatest care, in allusion to the ark of the testimony in the tabernacle and temple. The prefect, however, reads the portions of the law and hagiography without any difficulty. The same is done by the remains of the Samaritans at this day. Every oriental scholar knows that the people of these countries look upon consonants as the stamina of words. Accordingly, in writing letters, in dispatches upon business, and all affairs of small moment, the vowels are generally omitted. It is obvious, that in every original language the sound of the vowels is variable and of little importance. Such was the case with the Hebrew tongue. Nor do we think that the natives of the country would find it a matter of much difficulty to learn to read without the help of the vowels. They knew the words before hand, and so might readily enough learn by practice what vowels were to be inserted.

Proof that the Masoretic points are modern.

When the Hebrew became a dead language, as it certainly was in a great measure to the vulgar, after the return from the Babylonian captivity, such subsidiaries might we think, have been useful, and of course might possibly have been adopted for the use of the vulgar; but the scribe, the lawyer, and the learned rabbi, probably disdained such beggarly elements. We shall in this place hazard a conjecture, which, to us at least, is altogether new. We imagine that the Phœnicians, who were an inventive and ingenious people, had, prior to the age of Cadmus, who first brought their letters into Greece, adopted the more commodious method of inserting the vowels in their proper places; whereas the Jews, zealously attached to the customs of their ancestors, continued to write and read without them. In this manner the Gephuræi,[3] who were the followers of Cadmus, communicated them to the Iones, their neighbours. We are convinced that the materials of the Greek tongue are to be gleaned up in the east; and upon that ground we have often endeavoured to trace the origin of Greek words in the Hebrew, Phœnician, Chaldean, and Arabian languages. Reading without the vowel points we have seldom failed in our search; but when we followed the method of reading by the Masoretic points, we seldom succeeded; and this, we believe, every man of tolerable erudition who will make the trial, will find by experience to be true. This argument appears to us superior to every objection. Upon this basis, the learned Bochart has erected his etymological fabric, which will be admired by the learned and ingenious as long as philology shall be cultivated by men.

It has been urged by the zealots for the Masoretic system, that the Arabians and Persians employ the vowel points. That they do so at present is readily granted; but whether they did so from the beginning is the question to be resolved. That Arabia was overspread with Jewish exiles at a very early period, is abundantly certain. It was natural for them to retire to a land where they would not hear of war, nor the sound of the trumpet. Accordingly we find that, prior to the age of the Arabian impostor, Arabia swarmed with Jewish settlements. From these Jews, it is highly probable that their neighbours learned the use of the points in question; which in the course of their conquests the Saracens communicated to the Persians.

It has been alleged with great show of reason, that without the vowel points, it is often impossible to develope the genu-

Hebrew Language.

ine signification of many words which occur frequently in the language, and that many words of different and sometimes opposite significations are written with exactly the same consonants. Without the points, then, how are we to know the distinction? In answer to this objection, we beg leave to observe, that, during the first period of a language, it is impossible that there should not occur a number of similar sounds of different significations. This is surely to be attributed to the poverty of the language. When a few terms have been once fabricated, men will rather annex new significations to old terms, than be at the expense of time or thought to invent new ones. This must have been the case with the Hebrew in particular; and indeed no language on earth is without instances of this inconveniency, which, however, in a living tongue, is easily overcome by a difference of accent, tone, gesture, pronunciation; all which, we think, might obviate the difficulty.

From the preceding arguments, we think ourselves authorised to infer that the Masora is a novel system, utterly unknown to the most ancient Jews, and never admitted into those copies of the Scriptures which were deemed most sacred and most authentic by that people.

With respect to the original introduction of the points, we agree with the learned and judicious Dr. Prideaux,[1] who imagines that they were gradually introduced after the Hebrew became a dead language, with a view to facilitate the learning to read that language, more especially amongst the vulgar. By whom they were introduced, cannot, we think, be easily determined; nor is it probable that they were all introduced at once, or by one and the same person. They have been ascribed to Ezra by many, for no other reason that we can discover, but to enhance their authenticity, and because the sentiment is analogous to the other articles of reformation established by that holy priest. If the curious reader should not be satisfied with the preceding detail, we must remit him to Copellus and Morinus, on the one side, and the two Buxtorfs, Schultens, and Dr. James Robertson, formerly professor of oriental languages in the university of Edinburgh, on the other. This learned orientalist, in his dissertation prefixed to his *Clavis Pentateuchi*, has collected and arranged, with the true spirit of criticism, every thing that has been advanced in favour of the Masoretical system. *Si Pergama dextra defendi possent, etiam hac defensa fuissent.*

Origen's Hexapla.

St. Origen, who flourished about the beginning of the third century, was a profound Hebrew scholar. He published a most laborious and learned work, which is generally called the *Hexapla*, because it consisted of six columns, the first of which contained the Hebrew text; the second, the same text, but written in Greek characters; the third column exhibited the version of Aquila; the fourth that of Symmachus; the fifth, the Septuagint; and the sixth, the version of Theodotan. In some fragments of that great work which are still extant, we have a specimen of the manner in which the Hebrew was pronounced in the third century, by which it appears that it was very different from that which results from observing the Masoretical points. The following is an instance copied from the beginning of Genesis.

According to Origen.

בראשית ברא אלהים את השמים ואת הארץ : והארץ
היתה תהו ובהו והשך על־פני תהום ורוה אלהים מרחפת
על־פני המים : ויאמר אלהים יהי אור ויהי־אור : וירא
אלהים את־האור כי־טוב ויבדל אלהום בין האור ובין
החשך : [2]

According to the Masorites.

Hebrew Languag

בְּרֵאשִׁית בָּרָא אֱלֹהִים אֵת הַשָּׁמַיִם וְאֵת הָאָרֶץ : וְהָאָרֶץ

הַחֹשֶׁךְ : [3]

Practice o the ancie Greeks.

Upon the whole, we presume to give it as our opinion, that in the most early periods, the vowels, *aleph*, *he*, *jod* or *yod*, *vaw* or *waw*, and perhaps *oin* or *ajin*, were regularly written wherever they were sounded. This appears to us plain from the practice of the ancient Greeks. It is agreed upon all hands that the Samaritan and Phœnician alphabets were the same; and that the former was originally the same with that of the Jews. The Phœnicians certainly wrote the vowels exactly, for so did the Greeks who copied their alphabet. If the Phœnicians wrote their vowels, so then did the Jews of the age of Cadmus; but as Cadmus was contemporary with some of the earliest judges of Israel, the consequence is evident, namely, that the Jews wrote their vowels as late as the arrival of that stranger in Greece. We ought naturally to judge of the Hebrew by the Chaldaic, Syriac, and Arabic, its sister dialects. But in ancient times all these languages had their vowels regularly inserted; and why not the Hebrew in the same manner with the rest?

As these first vowels which were coeval with the other letters, often varied in their sound and application, the points, in all appearance, were first invented and employed to ascertain their different sounds in different connections. Other marks might be invented to point out the various tones of voice, like the τονοι, or accents, with which the vowels were to be enounced, as was done amongst the later Greeks. In process of time, in order to promote celerity of writing, the vowels were omitted, and the points substituted in their place.

Before we conclude our observations on the Hebrew language, we ought perhaps to make an apology for omitting to interlard our details with quotations from the two Talmuds, the Mishna, the Gemara, the Cabbalas, and a multitude of Rabbinical writers who are commonly cited upon such an occasion. We believe we could have quoted almost numberless passages from the two Buxtorfs, Father Morin, Capellus, and other Hebrew critics, with no great trouble to ourselves, and little advantage to the far greater part of our readers. But our opinion is that such a pedantic display of philological erudition would probably have excited the mirth of our learned, and roused the indignation of our unlearned, readers. Our wish is, to gratify readers of both descriptions, by contributing to the edification of one class without disgusting the other. We cannot, however, take leave of the sacred language, without giving a brief detail of those excellencies, which, in our opinion, give it a just claim to superiority over those other tongues which have sometimes contended with it for the prize of antiquity; and of these the following in our apprehension deserve particular notice.

Excellen- cies of th Hebrew language

If this language may claim any advantage over its antagonists, with respect to its being rather a mother than a daughter of any of them, it is undoubtedly in consequence of its simplicity, its purity, its energy, its fecundity of expressions and significations. In all these, notwithstanding

Hebrew language.

its paucity of words, it excels the vast variety of other languages which are its cognate dialects. To these we may add the significancy of the names, both of men and brutes; the nature and properties of the latter of which are more clearly and more fully exhibited by their names in this than in any other tongue hitherto known. Besides, its well authenticated antiquity, and the venerable tone of its writings, surpass any thing left upon record in any other dialect now extant in the world. These extraordinary qualities must excite our admiration under every disadvantage; and from the same circumstance we may infer its incomparable beauty in the age of the Jewish legislator, and what effects it would naturally produce, could we know it now as it was spoken and written in the days of David and Solomon.

As far, however, as we understand it in its present mutilated condition, and are able to judge of its character from the few books which have come down to our time, we plainly perceive that its genius is simple, primitive, natural, and exactly conformable to the character of those uncultivated patriarchs who used it them themselves, and transmitted it to their descendants in its native purity and simplicity. Its words are comparatively few, yet concise and expressive; being derived from a very small number of radicals, without the artificial composition of modern languages. No tongue, ancient or modern, can rival it in the happy and rich fecundity of its verbs, resulting from the variety and significancy of its conjugations; which are so admirably arranged and diversified, that by changing a letter or two of the primitive, they express the various modes of acting, suffering, motion, rest, &c., in so precise and significant a manner, that frequently in one word they convey an idea which, in any other language, would require a tedious paraphrase. These positions might easily be illustrated by numerous examples; but to the Hebrew scholar they would be superfluous, and to the illiterate neither interesting nor entertaining.

To these we may add the monosyllabic tone of the language, which, by a few prefixes and affixes without affecting the radix or root, varies the signification almost at pleasure, whilst the method of affixing the person to the verb exhibits the gender of the object introduced. In the nouns of this language there is no flexion excepting what is necessary to point out the difference of gender and number. Its cases are distinguished by articles, which are merely single letters placed at the beginning of the word. The pronouns are only single letters affixed; and the prepositions are of the same character prefixed to words. Its words follow one another in an easy and natural arrangement, without intricacy or transposition, without suspending the attention or involving the sense by intricate and artificial periods. All these striking and peculiar excellencies combined, plainly demonstrate the beauty, the stability, and the antiquity of this most interesting and remarkable language.

We would not, however, be thought to insinuate that this tongue continued altogether without changes and imperfections. We admit that many of its radical words were lost in a course of ages, and that foreign ones were substituted in their place. The long sojourning of the Israelites in Egypt, and their close connection with that people, even *quoad sacra*, must have introduced, into the vulgar dialect at least, a multitude of Egyptian vocables and phrases which have gradually been incorporated with the written language, and in process of time have become part of its essence. In Egypt, the Israelites imbibed those principles of idolatry which nothing less than the final extirpation of their polity could eradicate. If that people, then, were so obstinately attached to the Egyptian idolatry, it is not very probable that they would be averse to adopt the Egyptian language. Besides, the Scripture informs us, that there departed out of Egypt a mixed multitude; a circumstance which must have infected the Hebrew language with the dialect of Egypt. Hence, as none of the genuine Hebrew radicals exceed three letters, whatever words exceed that number in their radical state may justly be deemed of foreign extraction.

Arabic Language.

Some Hebrew critics have thought that verbs constitute the radicals of the whole language. But this opinion appears to us to be ill-founded; for although many Hebrew nouns are undoubtedly derived from verbs, we at the same time find numbers of the latter deduced from the former.

Hutchinsonianism.

Before we conclude what we have to say of the Hebrew tongue, our readers may possibly imagine that we ought to give some account of the Hutchinsonian system, which was at one time so highly in vogue. But as this allegorical scheme of interpretation is now in a great measure exploded, we shall beg leave to refer the curious Hebraist to Mr. Holloway's *Originals*, a small book in two volumes octavo, but replete with multifarious erudition, especially in the Hutchinsonian style and character. *Fides sit penes autorem.*

SECT. II. THE ARABIC LANGUAGE.

Arabic language originally Hebrew.

We shall now proceed to give some account of the Arabian language, which is evidently one of the sister dialects of the Hebrew. Both, we imagine, were originally the same; the former highly improved and enlarged; the latter, in appearance, retaining its original simplicity and rude aspect, spoken by a people of a genius by no means inventive. In this inquiry, too, as in the former, we shall spare ourselves the trouble of descending to the grammatical minutiæ of the tongue; a method which, we are persuaded, would neither gratify our learned nor edify our unlearned readers. To those who are inclined to acquire the first elements of that various, copious, and highly improved tongue, we beg to recommend Erpenii *Rudimenta Linguæ Arabicæ;* Golii *Grammatica Arabica;* the Dissertations of Hariri, translated by the elder Schultens; and Mr. Richardson's Persic and Arabic Grammar.

We have said that the Hebrew and the Arabic are sister dialects, a relation which, as far as we know, has been seldom controverted; but we think there is authentic historical evidence that they were positively one and the same, at a period when the one as well as the other appeared in its infant unadorned simplicity. The following detail will, we hope, fully authenticate the truth of our position.

"Unto Eber," says the Scripture,[1] "were born two sons. The name of one was Peleg, because in his days the earth was divided; and his brother's name was Joktan," or rather Yoktan. This last, says the sacred historian, "had thirteen sons; and their dwelling reached from Mesha (Mocha) to Sephar,"[2] a mount of the east. According to this account, the descendants of Yoktan possessed all the maritime coasts of Arabia from Mesha (Mocha) to Mount Sephar towards the east of that peninsula. Moses, describing the rivers of paradise, tells us, that one of the branches of that river[3] "encompassed the whole land of Havilah, where there was great store of gold." Havilah was the twelfth son of Yoktan, whom the Arabians call Kobtan; and consequently his territory was situated towards the eastern limit of the possessions of the posterity of the youngest son of Eber. Yoktan or Kobtan was too young to be concerned in the building of the tower at Babel; and consequently he retained the language of his family, which was undoubtedly the Hebrew. His descendants must have carried the same language into their respective settlements, where it would be regularly transmitted to succeeding generations. The original language of all the tribes of the Arabians who inhabit a vast tract of country along the southern shore was, according to this deduction, that of their father Kobtan, in other words, the Hebrew. Indeed, the most learned Arabians of modern times unanimously acknowledged this patriarch as the founder of their language as well as of their nation.

[3] Gen. ii. 11.

The other districts of Arabia were peopled by the offspring of Abraham. The Ishmaelites, the posterity of that patriarch by Hagar, penetrated into the very centre of the peninsula, where they incorporated, and in process of time became one people with the Kobtanites. Another region was possessed by the children of the same holy man by Cheturah his second wife. The Moabites, Ammonites, Edomites, Amalekites, and others, who settled in the various regions of Arabia Petræa, were all branches of Abraham's family, and used the same language with their great progenitor. The Scripture indeed speaks of people who inhabited the country last mentioned prior to the branches of Abraham's family; but these, according to the same history, were extirpated by the former. The conclusion then is, if we credit the Mosaic account, that all the inhabitants of the three divisions of Arabia did, in the earliest periods, universally use the Hebrew tongue.

We are sensible that there was a region of Arabia inhabited by the Cushim, or descendants of Cush. This district was situated on the confines of Babylonia. Our translators have confounded this country with the modern Ethiopia, and consequently ascribed the exploits performed by the Arabian Cushim to the Ethiopians. The Arabian kings of Babylon were of those Cushim; but they were conquered and expelled Babylonia by the Chasidim. The latter spoke the Chaldean dialect, as will appear when we come to speak of that of the Abyssinians. Here the reader is desired to reflect that the Hebrew and Chaldaic are cognate dialects.

The foregoing proofs, deduced from the Mosaic history, will be corroborated by a mass of internal evidence brought forward in succeeding parts of our inquiry.

Gradual deviation from simplicity.

The Arabic tongue, originally pure Hebrew, was in process of time greatly transformed and altered from its simple unsophisticated state. The Arabians were divided into many different tribes, a circumstance which naturally produced many different dialects. These, however, were by no means of foreign growth. No foreign enemy ever conquered these independent hordes. The Persians, Greeks, and Romans, sometimes attempted to invade their territories; but the roughness of the ground and the scarcity of forage, the penury of water and their natural bravery, always protected them. They were indeed once invaded by the Abyssinians or Ethiopians with some show of success; but these invaders were in a short time expelled the country. Their language, of consequence, was never adulterated with foreign words or exotic phrases and idioms. Whatever augmentations or improvements it received were derived from the genius and industry of the natives, and not from adventitious or imported acquisitions. From this circumstance we may justly infer, that the Arabian tongue was a long time stationary, and of course differed in no considerable degree from its Hebrew archetype. The learned Schultens, in his Commentary on Job, has shown, to the conviction of every candid inquirer, that it is impossible to understand that sublime composition without having recourse to the Arabic idioms. That patriarch was a Chuzite, and his country might be reckoned a part of Arabia. His three friends were actually Arabians, being the descendants of Ishmael and Esau. His country bordered on that of the predatory Chaldeans, who were an Arabian banditti. Hence, when we consider all these circumstances *in cumulo*, we are strongly inclined to believe that the book of Job was actually written in Arabic, as the language stood at that period; which, according to the most probable opinion, could not have been later than the age of Moses. The learned are generally agreed that this whole book, the three first chapters excepted, is a poetical composition, replete with the most brilliant and magnificent imagery, the boldest, the justest, and most gorgeous tropes and allusions, and a grandeur of sentiment wholly divine. Whoever has read with any degree of taste, the poetical compositions of the modern Arabians, on divine subjects, will, we flatter ourselves, discover a striking similarity both of diction and sentiment. Be this as it may, we think there is no reason to conclude that the Arabic dialect deviated much from the Hebrew standard prior to the Christian era.

Principal dialects of Arabia.

Of those different dialects which prevailed amongst the various tribes amongst which the peninsula of Arabia was divided, the principal were the Hemyaret and the Koreish. Though some of these were tributary to the Tobbas, or Hemyaret sovereign of Arabia Felix, yet they took no great pains to cultivate the language of that province, and of course these people did not thoroughly understand it. As for the independent tribes, they had no temptation to cultivate any other language than their own.

Dialect of the Koreish.

The Koreish tribe was the noblest and the most learned of all the western Arabs; and the kaaba, or square temple of Mecca, was prior to the era of Mohammed solely under their protection. This temple drew annually a great concourse of pilgrims from every Arabian tribe, and indeed from every other country where the Sabian religion prevailed. The language of the Koreish was studied with emulation by almost all the neighbouring tribes. Numbers of the pilgrims were people of the first rank, and possessed all the science peculiar to their country and their age. Great fairs were held during their residence at Mecca, and a variety of gay amusements filled up the intervals of their religious duties. In these entertainments literary compositions bore the highest and most distinguished rank; every man of genius considering not his own reputation alone, but even that of his nation or his tribe, as interested in his success. Poetry and rhetoric were chiefly esteemed and admired; the former being looked upon as highly ornamental, and the latter as a necessary accomplishment in the education of every leading man. An assembly at a place called Ocadh, had been in consequence established about the end of the sixth century, where all were admitted to a rivalship of genius. The merits of their respective productions were impartially determined by the assembly at large, and the most improved of their poems, written on silk, in characters of gold, were with much solemnity suspended in the temple, as the highest mark of honour which could be conferred on literary merit. These poems were called the *Moallabat*, suspended, or *Modhabebat*, golden. Seven of these are still preserved in European libraries.

From this uncommon attention to promote emulation and refine their language, the dialect of the Koreish became the purest, the richest, and the most polite, of all the Arabian idioms. It was studied with a kind of predilection; and about the beginning of the seventh century it was the general language of Arabia, the other dialects being either incorporated with it, or sliding gradually into disuse. By this singular idiomatic union, the Arabic has acquired a prodigious fecundity; whilst the luxuriance of synonymes, and the equivocal or opposite senses of the same or similar words, have furnished their writers with a wonderful power of indulging, in the fullest range, their favourite passion for antithesis and quaint allusion. One instance of this we have in the word *veli*, which signifies a prince, a friend, and also a slave. This same word, with the change of one letter only, becomes *vali*, which, without equivocation, imports a sovereign. Examples of this kind occur in almost every page of every Arabic dictionary.

Superiority of this dialect modern.

But all these advantages of this incomparable language are merely modern, and do not reach higher than the beginning of the sixth century. Prior to that era, as we have

abic
L uage.

observed above, a variety of dialects obtained; and as the Arabs were by their situation in a manner sequestered from all the rest of mankind, it may not perhaps be superfluous to inquire briefly into the cause and origin of this instantaneous and universal change.

During a course of more than twenty centuries, the Arabians had been shut up within the narrow limits of their own peninsula, and in a great measure secluded from the rest of the world. Their commerce with India was purely mercantile, and little calculated to excite or promote intellectual improvements. They traded with the Egyptians from time immemorial; but since the invasion and usurpation of the pastor kings, every shepherd, that is, every Arabian, was an abomination to the Egyptians. From that quarter, therefore, they could not derive much intellectual improvement. Besides, when an extensive territory is parcelled out amongst a number of petty septs or clans, the feuds and contests which originate from interfering interests and territorial disputes, leave but little time, and less inclination, for the culture of the mind. In these circumstances, the military art alone will be cultivated, and the profession of arms alone will be deemed honourable. Of consequence, we find that, in the general opinion, poetry, rhetoric, and the profession of arms, were the only pursuits cultivated by the people in question. As for the science of war, we are convinced that it was both studied and practised at a very early period; but with regard to the two former, we imagine they were very late acquisitions, and sprung from some circumstance external and adventitious.

The tribe of the Koreish were much engaged in commerce. They exported frankincense, myrrh, cassia, galbanum, and other drugs and spices, to Damascus, Tripoli, Palmyra, and other commercial cities of Syria and its neighbourhood. Upon these occasions the Arabian traders must have become acquainted with the Greek language, and perhaps with the more amusing and affecting parts of the Grecian literature. They might hear of the high renown of Homer and Demosthenes; and it is not impossible that some of them might be able to read their compositions. Every body knows with what unremitting ardour the learned Arabs under the first caliphs, perused and translated the philosophical works of the Grecian sages. The very same spirit might animate their predecessors, although they wanted learning, and perhaps public encouragement, to arouse their exertions. From this quarter, we think, the Arabs may have learned to admire, and then to imitate, the Grecian worthies.

In ution
at ecca
sim r to
the lymp
pic mes.

The Ptolemies of Egypt were the professed patrons of commerce as well as of learning. Under these princes all nations were invited to trade with that happy country. The Arabs, now no longer fettered by Egyptian jealousy, carried their precious commodities to Alexandria, where the Grecian literature, though no longer in its meridian splendour, shone however with a clear unfaded lustre. The court of the first Ptolemies was the retreat of all the most celebrated geniuses of Greece and of the age; in a word, Alexandria was the native land of learning and ingenuity. Here the ingenious Arab must have heard the praises of learning incessantly proclaimed, and must have often been present at the public exhibitions of the poets and orators; and even although he did not exactly understand them, he might be charmed with the melody of the diction, and struck with surprise at their effects on the audience. The reader will please to reflect, that the Arabian traders were the first men of the nation, with respect to birth, learning, and fortune. These wise men, to use the language of Scripture, inspired with the natural curiosity of their race, might hear of the celebrated Olympic games, the public recitations before the people there assembled, and the glorious prize bestowed upon the conquerors. Such information might animate them to institute something parallel at Mecca, with a view to improve their language, and at the same time to derive honour and emolument to themselves. The Koreishim might promise themselves the like advantages from the establishment of the fair and assembly at Ocadh, as the natives of Elis derived from the institution of the Olympic games. For these reasons, we conjecture, the literary competitions at the place just mentioned were instituted at so late a period, although the nation had existed more than two thousand years before the establishment of this anniversary. Upon the whole, we are inclined to believe, that the Arabs, notwithstanding all the fine things recorded of them by their own poetical historians, and believed perhaps too easily by those of other countries, were in the days of ignorance like the earliest Romans, *latrones et semibarbari.* For our part, we think it by no means probable, that a people of that character should, after so long a course of years, have stumbled upon so laudable and so beneficial an institution, without taking the hint from some foreign one of a similar kind. This we acknowledge is only a conjecture, and as such it is submitted to the judgment of the reader.

Arabic
Language.

There were, as has been observed above, two principal dialects of the original Arabic: the Hamyarite, spoken by the genuine Arabs; and the Koreishite, or pure Arabic, which at last became the general language of that people. The former of these inclined towards the Syriac or Chaldaic; the latter being, according to them, the language of Ishmael, was deeply tinctured with the Hebrew idiom. The oriental writers tell us that Terah, the grandfather of Hamyar, was the first whose language deviated from the Syriac to the Arabic. Hence, say they, the Hamyaritic dialect must have approached near to the purity of the Syriac, and consequently must have been more remote from the true genius of the Arabic than that of any of the other tribes. The fact seems to stand thus: The Hamyarites were neighbours to the Chaldeans and Syrians, and consequently were connected with those people by commerce, wars, alliances, and other kinds of intercourse. This circumstance introduced into their language many phrases and idioms from both these nations. That Terah was concerned in adulterating the dialect of the Hamyarites, is a mere oriental legend, fabricated by the Arabs, after they began to peruse the Hebrew Scriptures. The Koreish being situated in the centre of Arabia, were less exposed to intercourse with foreigners, and therefore preserved their language more pure and untainted.

The Koran
written in
the Koreish
dialect.

The learned well know, that the Koran was written in the dialect of the Koreish, a circumstance which communicated additional splendour to that branch of the Arabian tongue. It has been proved, that the language of the original inhabitants of Arabia was genuine Hebrew. But upon this supposition a question will arise, namely, whether the Arabians actually preserved their original tongue pure and unsophisticated during a space of about three thousand years, which elapsed between the deluge and birth of Mohammed; or whether, during that period, according to the ordinary course of human affairs, it underwent many changes and deviations from the original standard.

The admirers of that language strenuously maintain the former position; others, who are more moderate in their attachment, are disposed to admit the latter. Chardin observes of the oriental languages in general, that they do not vary and fluctuate with time like the European tongues.[1] " Ce qu'il y a de plus admirable, dit il, et de plus remarquable, dans ces langues, c'est, qu'elles ne changent point, et n'ont point changé du tout, soit à l'égard de termes, soit à l'égard du tour: rien n'y est, ni nouveau ni vieux, nulle bonne façon de parler n'a cessé d'être en credit. L'Alcoran, par exemple, est aujourdhui, comme il y a mille années, le

---

[1] *Voyages,* vol. iii. p. 43.

modèle de la plus pure, plus courte, et plus eloquente diction." It is not to our purpose to transcribe the remaining part of the author's reflection upon this subject. From the above it plainly appears that he concludes, that the Arabian tongue has suffered no change since the publication of the Koran; and at the same time insinuates, that it had continued invariable in its original purity through all ages, from the days of Kobtan to the appearance of that book. Whether both or either of these sentiments be properly authenticated will appear in the sequel.

Means adopted by the Arabs to preserve the purity of their language.

The learned Dr. Robertson, professor of oriental languages in the university of Edinburgh, informs us that the Arabians, in order to preserve the purity of their language, strictly prohibited their merchants, who were obliged to go abroad for the sake of commerce, all intercourse with strange women. We know not where this injunction is recorded, but certainly it was a most terrible interdict to an amorous son of the desert. If such a prohibition actually existed, we suspect it originated from some other source than the fear of corrupting their language. Be this as it may, however, the Doctor, as well as the great Schultens, is clearly of opinion that the language in question, although divided into a great number of streams and canals, still flowed pure and limpid in its course.

The style of the Koran now obsolete.

Our readers who are acquainted with the history of the orientals, are already apprised of the steady attachment of those people to ancient customs and institutions. We readily allow, that in the article of language this same predilection is abundantly obvious; but every oriental scholar must confess, that the style of the Koran is at the present day in a manner obsolete, and has become almost a dead language. This fact, we believe, will not be questioned. If the Arabian has deviated so very considerably from the standard of the Koran in little more than one thousand years, and that too after an archetype is ascertained, we may by a parity of reason infer, that much greater deviations must have affected the language in the space of three thousand years. It is universally allowed by such as maintain the unsullied purity of the Arabian tongue, that it was originally the same with the Hebrew, or, in other words, with the ancient Syriac and Chaldaic. Let any one now compare the words, idioms, and phraseology of the Koran with the remains of those three languages, and we think we may venture to affirm that the difference will be palpable. This circumstance, we think, indicates in the strongest terms a remarkable alteration.

The Arabs themselves are agreed, that notwithstanding the amazing fecundity of their language, vast numbers of its radical terms have been irrecoverably lost. But this loss could not be supplied without either fabricating new words, or borrowing them from foreign languages. To the latter method we have seen their aversion, and must therefore conclude that they adopted the former. The Chaldeans, Syrians, and Phœnicians, had made innovations on their language at a very early period, even before conquests were undertaken; and we see no reason to suppose that the Arabs did not innovate as well as their nearest neighbours.

It resembles the Hebrew in its phraseology.

There are, we think, very strong reasons to believe, that Job was an Arabian, and flourished prior to Moses, perhaps as early as Jacob. The style, the genius, and the figurative tone of the composition; the amazing sublimity of the sentiments, the allusions, the pathos, the boldness, the variety and irregularity, and the poetical enthusiasm which pervade the whole poem, strongly breathe the Arabian spirit; indeed the very diction is peculiar to that single book, and differs widely from that of the Psalms and every poetical part of the sacred canon. If we compare this book with Mohammed's Koran, we shall scarcely find any resemblance of words or phraseology, but a wonderful similarity of figures, enthusiasm, and elevation of sentiments. We are then led to conclude, that the Arabic did actually lose and gain a multitude of vocables between the era of its first establishment amongst the descendants of Joktan and Ishmael, and the birth of the impostor.

The art of writing was introduced amongst the Arabs at a very late period. Without the assistance of this art, one would think it altogether impossible to preserve any language in its primæval purity and simplicity. As the curious reader may here expect some account of the Arabic characters: the following detail is the most probable one we have been able to collect on the subject.

Art of writing amongst Hamyarites.

It is generally agreed, that the art of writing was known amongst the Hamyarites or Homerites at a very early period.[1] These people were sovereigns of Arabia during a course of many years. The character of their graphic system was somewhat perplexed and confused. It was called *al Mosnad*, from the mutual connection of the letters. The alphabet of these people resembled that of the Hebrews both in the number and order of the letters, and was called *abgad heviz*,[2] from the first ten letters of the Hebrew alphabet, artificially thrown together. "And this word," says the learned Chardin[3] "*a*, *b*, *g*, *d*, is formed of the four letters which were heretofore the first in the Arabian language, as they are still in that of the Hebrews." The same traveller is positive that these were the ancient characters of the Arabs; that they differed from the Cuphic letters, which were afterwards introduced; and that they were also furnished with vowel points. These, we imagine, were the first sketches of the Chaldaic characters, which probably the Hamyarites retained in their pristine unpolished form, after they had been polished and reduced to a more elegant size by the original inventors.

Monuments bearing inscriptions in these characters are, they tell us, still to be seen in several places of Arabia. Some were engraved upon rocks; and to these we think it probable that the patriarch Job alludes in those passages where he seems to intimate an inclination to have his sufferings recorded in a book, and graven in the rock for ever. All the Arabians agree, that the dialect of the Hamyarites inclined towards the Syriac or Chaldaic. This we have imputed to the connection of that people with the Chaldeans, who lived in their neighbourhood. If the Hamyaritic dialect was infected with the Syriac or Chaldaic, there can be no doubt that they derived their letters from the same quarter.

We conclude, then, that the Hamyarites knew the art of writing from the earliest antiquity, and that the letters they employed were the rude Chaldaic in their unimproved state.[4] Some of the Arabians do indeed hold, that Ishmael was the first author of letters, but that his characters were rude and indistinct, without any interval between letters or words, and that these were adopted by Kedar and his other children. This tradition, however, has met with little credit.

Art of writing amongst Koreishites.

With respect to the highly polished Koreishites, it is agreed on all hands, that they were unacquainted with the use of letters until a few years before the birth of Mahommed. But two difficulties here present themselves. The first is, how the Koreishite dialect, without the art of writing, happened to excel all the other dialects of the Arabic tongue, assisted by that art, which is apparently so necessary for preserving a language in its original purity. The second is, we think, still greater, namely, how the Koreish came to learn that most useful art at so late a period as the sixth century. It is a well known fact, that ever after the Babylonian captivity Arabia swarmed with Jewish villages, in

rabic
nguage.

which the art of writing was generally known; and almost at the beginning of the Christian era, multitudes of Christians retired to the same country, in order to avoid the persecutions which they suffered in the Roman empire. In these circumstances, we think it rather strange, that the Koreishites, highly polished and acute as they were, never thought of embracing the opportunity of learning an art so useful. These two problems we leave to be solved by our more learned readers.

But however they be solved, it is universally acknowledged, that the Koreish were ignorant of letters till a few years before the birth of their prophet. Ebn Chalican,[1] one of their most celebrated historians, informs us, that Moramer the son of Morra, an Anbarian, or native of Anbaris, a city of Irak,[2] first invented alphabetical characters, and taught his countrymen to use them, and that from the latter this noble invention was derived by the Koreishites. These letters, though neither beautiful nor convenient, were long used by the Arabs. They were denominated *Cuphic*, from Cupha, a city of Irak. In these characters the original copy of the Koran was written. They were probably the original clumsy characters which were retained by the vulgar, after the beautiful square Chaldaic letters had been invented, and probably used by priests, philosophers, and the learned in general. These letters are often at this day used by the Arabs for the titles of books and public inscriptions.

proved
ut three
dred
rs after
bam-
r.

Abauli the son of Mocla,[3] about three hundred years after the death of Mohammed, found out a more elegant and more expeditious character. This invention of Abauli was afterwards carried to perfection by Ebn Bowla, who died in the year of the Hegira 413, when Kader was caliph of Bagdad. This character, with little variation, obtains at the present day. As we think this article of some importance, we shall, for the sake of our unlearned readers, transcribe an excellent account of the whole matter from the very learned Schultens.

The Cuphic character, says he, which had been brought from the region of the Chaldeans to the province of Hejaz, and to Mecca its capital, in the age of Mohammed, was employed by the Koreishites, and in it the Koran was first written. But as this character was rude and clumsy, in consequence of its size, and ill calculated for expedition, Abauli Ebn Mocla devised a more elegant and expeditious one. This person was visir to Arradius, the forty-first caliph, who began to reign in the year of the Hegira 322. Accordingly, in the tenth century, under this emperor of the Saracens, the form of the Arabian alphabet underwent a change; and the former clumsy embarrassed character was made to give way to the polished, easy, and expeditious type. Regarding this expedition alone, the author of the invention left very few vowel characters; and as the Hebrew manner of writing admits five long ones and five short in different shapes, he taught how to express all the vowels, both long and short, suitably to the genius of the language, by three, or rather by two, small points, without any danger of a mistake, an abbreviation truly deserving applause and admiration; for by placing a very small line above بَ he expressed *a*, and *e*; and by placing the same below بِ he meant to intimate *i* only. To the other short ones, *o* and *u*, he assigned a small *waw* above. In order to represent the long ones, he called in the *matres lectionis*, the "quiescent letters א, ו, י;" so that *phata* with *elif* intimated *a* and *o* long, that is, *kametz* and *cholem*; *jod* placed after *kefram* became *tzeri* and *chirek* long. *Waw* annexed to *damma* made *schurek*.

In this passage, the great orientalist acknowledges that the visir above mentioned, who carried the Arabian alphabet to the pinnacle of perfection, invented and annexed the vowel points for the sake of ease and expedition in writing; from which we may infer, that prior to the tenth century the Arabians had no vowel points, and consequently either read without vowels, or contented themselves with the *matres lectionis* above mentioned.

Arabic
Language.

The design of the author of the invention, in fabricating these points, was confessedly ease and expedition in writing; a circumstance which furnishes a strong presumption that the Hebrew vowel-points were devised and annexed at some late period for the very same purposes. Some, indeed, have gone so far as to affirm that the Arabians were the original fabricators of the vowel-points. "The Arabians,"[4] says the learned Dr. Gregory Sharp, "were the original authors of the vowel-points. They invented three, called *fatha*, and *damma*, and *kefra*; but these were not in use till several years after Mohammed; for it is certain that the first copies of the Koran were without them. The rabbis stole them from the Arabs." This, however, is carrying the matter too far, since it is certain that the Jews were acquainted with the points in question long before the period above mentioned.

Extent of
the Arabic
language.

Though it is not our intention to enter into a minute detail of the peculiarities of this noble language, we cannot omit observing one thing, which indeed belongs to grammar, but is not generally taken notice of by the Arabic grammarians. The roots of verbs in this dialect are universally triliteral; so that the composition of the twenty-eight Arabian letters would give near twenty-two thousand elements of the language. This circumstance demonstrates the surprising extent of it. For although great numbers of its roots are irrecoverably lost, and some perhaps were never in use; yet if, without reckoning quadriliterals, we suppose ten thousand of them to exist, and each of them to admit only five variations, one with another, in forming derivative nouns, the whole language would then consist of fifty thousand words, each of which may receive a multitude of changes by the rules of grammar.

Again, the Arabic idiom seems to abhor the composition of words, and invariably expresses very complex ideas by circumlocution; so that if a compound word be found in any dialect of that language, we may at once pronounce it of foreign extraction. This is indeed a distinguishing feature in the structure of the Arabic, as well as in that of some of its sister dialects, and has, in our opinion, contributed not a little to the amazing fecundity of that language; for since every ingredient in the composition of a complex idea requires a word to express it, as many words became necessary to complete the language as there were simple ideas to be intimated by discourse. Were all the compounds of the Greek language to be dissolved, as probably once they were, the vocables of that tongue would infinitely exceed their present number.

The Arabic authors boast most unconscionably of the richness and variety of their language. No human understanding, say they, is capacious enough to comprehend all its treasures. Inspiration alone can qualify one for exhausting its sources.[5] Ebn Chalawalb, a most renowned grammarian of theirs, has spent a whole volume upon the various names of the lion, which amount to five hundred; and another on the names of the serpent, which make up two hundred. Mohammed al Firancabodius affirms that he wrote a book on the usefulness and different denominations of honey, in which he enumerates eighty of them; and after all, he assures us that he was still far from having exhausted his subject. To excel in a language so amazingly copious, was certainly a proof of uncommon capacity, and considered as no mean talent even amongst the Koreishites. Hence Mohammed, when some people were expressing their admiration of the eloquence of the Koran, told them that he had been taught by the angel Gabriel the language of Ishmael, which had fallen into desuetude.

Oratory and poetry of the Arabs.

In a language so richly replenished with the choicest and most energetic terms, both oratory and poetry were cultivated with ease. All the difficulty consisted in making a choice amongst words and phrases equally elegant. We may compare one of those poets or orators to a young gentleman, of a taste highly refined, walking into a repository where a profusion of the richest and most elegant dresses are piled up in wild confusion. The beau is here distressed with variety; but to be able to choose the most handsome and most becoming, he must have received from nature a superior good taste, and must likewise have cultivated it by assiduous industry, and by associating with the most genteel company.

The orations of the Arabians were of two kinds, metrical and prosaic. The former they compared to pearls set in gold, and the latter to loose ones. They were ambitious of excelling in both; and whoever did so, was highly distinguished. His success in either of those departments was thought to confer honour, not only on his family, but even on his tribe. In their poems were preserved the genealogies of their families, the privileges of their tribes, the memory of their heroes, the exploits of their ancestors, the propriety of their language, the magnificence of banquets, the generosity of their wealthy chiefs and great men, &c. After all, we cannot avoid being of the unpopular opinion, that this mighty parade of eloquence and poetry did not reach backwards above two centuries before the birth of Mohammed, as it certainly vanished at the era of the propagation of his religious institutions. The two succeeding centuries were the reigns of superstition and bloodshed. The voice of the muses is seldom heard amidst the din of arms.

The ancient Arabs, at whatever time poetry began to be in request amongst them, did not at first write poems of considerable length. They only expressed themselves in metre occasionally, in acute rather than harmonious strains. The Proverbs of Solomon, and the book of Ecclesiastes, seem to have been composed in this species of versification. The prosody of the Arabs was never digested into rules till some time after the death of Mohammed; and this is said to have been done by Al Khalti al Farabidi, who lived in the reign of the caliph Haroun al Raschid.

After so many encomiums on the copiousness of the Arabic tongue, one class of our readers may possibly expect that we should subjoin a brief detail of its genius and character; and this we shall do with all possible brevity.

Genius and character of the language.

All the primary or radical words of the language are composed of different combinations of consonants by *triads;* so that the various combinations and conjunctions of radicals make more than ten thousand, even without including those which may arise from the meeting of gutteral letters. From this quality of the language has flowed that stability of the dialect which has preserved it pure and entire for so many thousand years, and secured it from those changes and that fluctuation to which most other tongues are subject.

Perhaps notwithstanding its copiousness and variety, no other language can vie with the one in question in point of perspicuity and precision. It is possessed of a brevity and rotundity which, amidst the greatest variety, enables it to express with clearness and energy what could not be expressed in any other tongue without tedious circumlocutions. To this purpose we shall beg leave to transcribe a passage from Bishop Pococke's oration on the Arabic language. As we imagine that few of those readers who will have the curiosity to peruse this article can be unacquainted with the Latin tongue, we shall give it as it stands in the original without a translation:—

"Neque in nulla certe laudis parte, mira illa qua, non solum verborum in significando, perspicuitate, sed in prolatione, elegantiæ et dulcedini caverunt, sedulitas; quoque, non solum accurata, inter literas ex significata proportione, sensus vel intensione, vel remissione, prout res postulaverit, literarum appositione, subductione, vel juxta organorum, rationem prospexerunt; sed et ne quid delicatulis auribus ingratum, ne quid horridum, aut ἀσυμφωνον, reperiatur, effecerunt. Hoc in genere est, quod nuspiam in verbo aliquo, genuinæ apud Arabes originis, concurrunt, non intercedente vocalis alicujus motione consonantes, cum vel tres, vel plures, aliis in linguis frequenter collidantur. Immo neque, si adsint, quæ asperitati remedio sint, vocales, quas libet temere tamen committunt consonantes; sed ita rei natura postulat, ut concurrere debeant illa, quæ se invicem, sine asperitatis inductione consequi, et inter se connecti non possint; illi vel situs, vel literarum mutatione, eas abjiciendo, inserendo, emolliendo, aliisve quibus possent modis, remedia quærunt; adeo ab omni, quod vel absonum, vel dissonum est, abhorrent. Quod si nobis secus videntur, et asperius sonare ab Arabibus prolata, illud auribus nostris, et usui, non linguæ imputandum, nec mollius illis sonare nostra, quam eorum nobis censendum. Quin et gutturalium, quæ nobis maxima asperitatis causa videntur, absentiam, ut magnum in lingua Græca defectum, arguunt Arabes."

The learned Dr. Hunt, professor of the Hebrew and Arabic languages at Oxford, was of the same opinion with the very learned prelate, part of whose oration we have transcribed above, with respect to the delicacy and elegance of the Arabian language: "Nusquam, mihi credite, inquit ille, auribus magis parcitur quam in Arabia; nulla lingua a κακοφωνια, alienior quam Arabica. Quamquam enim nonnullæ ejus literæ minus fortasse suaviter, immo durius etiam sonuerint, ita tamen Arabes eas temperarunt cum lenibus, duras cum mollibus, graves cum acutis miscendo, voces inde non minus auribus jucundæ, quam pronunciatu faciles confecerint, totique sermoni miram sonorum tam dulcedinem quam varietatem addiderint. Quod quidem orationis modulandæ studium in Corano adeo manifestum est, ut primi Islamismi oppugnatores eum librum magica ideo arte scriptum dixerint. Non auribus tantum gratus est Arabismus, sed et animi conceptibus exprimendis aptus, sonos suos sententiis semper accommodans, et felici verborum junctura eorum naturam depingens."

To these we might add quotations from Erpenius's oration on the same subject, from Golius, Schultens, Hottinger, Bochart, and Sir William Jones; besides a whole cloud of oriental witnesses, whose extravagant encomiums would astonish rather than edify the greater part of our readers. These panegyrics may perhaps be in some measure hyperbolical; but in general we believe them to be pretty well founded. At the same time we are convinced that the Arabic, however melodious in the ears of a native, sounds harsh and unharmonious in that of an European.

Difficulty of acquiring a knowledge of it.

When we consider the richness and variety of the Arabic tongue we are led to conclude, that to acquire a tolerable degree of skill in its idioms, is a more difficult task than is generally imagined; at least some people who have with facility enough acquired a knowledge of the Greek and Latin, and likewise of the more fashionable modern languages have found it so. Be this as it may, however, there are two classes of men who, in our opinion, cannot handsomely dispense with the knowledge of a tongue almost universal; the gentleman, who is to be employed in the political transactions of the most respectable mercantile company upon earth, in the eastern parts of the world; and the divine, who applies himself to investigate the true import of the sacred oracles. Without this, the former will often find himself embarrassed in both his civil and mercantile negociations; and the latter will often grope in the dark, when a moderate acquaintance with that tongue would make all sunshine around him.

haldaic
nguage,
&c.

Bochart, Hottinger, Schultens, Pococke, Hunt, Robertson, and others, have taken wonderful pains, and lavished a profusion of learning, in proving the affinity and dialectical cognation between the Hebrew and Arabic. Much of this labour, we think, might have been spared. We presume to affirm, that no person tolerably versed in both languages can read a single paragraph of the Arabic version of the New Testament, or indeed of the Koran itself, without being convinced of the truth of this position. It is but stripping the latter of its adventitious frippery, and the kindred features will immediately appear.

The learned professors of the university of Leyden were the first who entered upon the career of Arabian learning. To them the European students are principally indebted for what knowledge of that language they have hitherto been able to attain. Though several Italians have contributed their endeavours, yet the fruit of their labours has been rendered almost useless by more commodious and more accurate works printed in Holland.

The palm of glory, in this branch of literature, is due to Golius, whose works are equally profound and elegant; so perspicuous in method, that they may always be consulted without fatigue, and read without languor. Erpenius's excellent grammar, and his memorable dictionary, will enable the student to explain the history of *Timur* by Ibn Arabshah. If he has once mastered that sublime work, he will understand the learned Arabic better than most of the Khatabs of Constantinople or of Mecca.

The Arabian language, however, notwithstanding all its boasted perfections, has undoubtedly shared the fate of other living languages; it has gradually undergone such considerable alterations, that the Arabic spoken and written in the age of Mohammed may be now regarded as a dead language. It is indeed so widely different from the modern language of Arabia, that it is taught and studied in the college of Mecca just as the Latin is at Rome.

The dialect of the Highlands of Yemen is said to have the nearest analogy to the language of the Koran, because these Highlanders have little intercourse with strangers. The old Arabic is throughout all the east, like the Latin in Europe, a learned tongue, taught in colleges, and only to be acquired by the perusal of the best authors.

SECT. III. OF THE CHALDAIC, PHŒNICIAN, AND EGYPTIAN LANGUAGES.

C nexion
o ese
la uages.

As there is a very strict connection and dialectical analogy amongst these languages, we have arranged them all under one section; especially since what is observed relating to one of them may, without the least straining, be extended to them all. We shall begin with the Chaldaic.

The Chaldeans, or Chasidim, as they are always called in Scripture, were the descendants of Chesed the son of Nahor, the brother of Abraham. The descendants of this patriarch drove the Cushim or Arabians out of Babylonia, and possessed themselves of that country at a very early period. As these Chasidim or Chaldeans were the posterity of Nahor, the descendant of Heber, they undoubtedly spoke the original Hebrew tongue as well as the other branches of that family. But being an ingenious and inventive people, they seem to have polished their language with much care and delicacy of taste.

The only genuine remains of the ancient Chaldaic language are to be found in the Hebrew Scriptures; and these are contained in two hundred and sixty-eight verses, of which we have two hundred in Daniel, reaching from verse 4th, chapter 2d, to chapter 8th exclusive; in Ezra sixty-seven, viz. in chapter 4th, seventeen verses, in chapter 5th, the same number, in chapter 6th, eighteen verses, and in chapter 7th, fifteen; in Jeremiah, chapter 10th, there is extant only one verse. From these fragments, compared with the Hebrew, it plainly appears, that the difference between that language and the Chaldaic is scarcely equal to that between the Doric and Ionic dialects of the Greek.

Chaldaic
Language,
&c.

Whatever might have been the form of the most ancient Chaldaic letters, it is generally known that the beautiful square characters, in which the Hebrew Scriptures began to be written after the age of Ezra, were current amongst them at an era prior to the Babylonian captivity. Those elegant characters were probably the invention of the Chaldean academies, which were established in various parts of that extensive and fertile country.

Chaldaic
differs little
from the
Hebrew.

The Chaldean declensions and conjugations differ so little from the Hebrew modifications, that it would be almost superfluous to dwell upon them in this section. The most effectual way to acquire an idea of the ancient Chaldaic, is to decompose the names confessedly of that dialect, which occur in many places of Scripture. By this method of proceeding, its beautiful structure and expressive energy will be readily comprehended even by the most illiterate class of readers. At the same time, we must observe, that the Chaldaic and the ancient Syriac bore so near a resemblance to each other, that they have generally been classed under one head.

The first Chaldaic word which occurs in the Old Testament is BARA, *creavit*. This word has all along been assigned to the language under consideration; for what reason, we confess we are not able to discover. The greater part of the Hebrew tongue is now lost. The words BAR, *a son*, and BARA, *creavit*, or rather *filiavit*, may probably be of that number. Another Scriptural word which is often quoted, and always ascribed either to the Syriac or Chaldaic, is *igar* or *jegar sahadutha*, which signifies a mountain of witnesses. Every body knows, that when Jacob and Laban made their compact, the latter denominated the heap of stones reared upon that occasion in this manner; whilst the former called it *Galeed*, as we now write and pronounce it. This pronunciation, however, does not appear to us altogether genuine. The word is probably compounded of גל, *gal*, *cumulus*, a heap, and עד, *chad*, *æternitas*, *seculum*, eternity, an age; so that גלעד, *galchad*, or *galaad* as it came to be written afterwards, signified an everlasting heap. Laban then had respect to the end for which the monument was erected; but Jacob alluded to its duration. It appears, however, upon this and every other occasion, when Chaldaic words are mentioned, that א, *a*, was a favourite letter both with the Syrians and Chaldeans. We may likewise observe, that the same people always changed the Hebrew ש, *shin*, into ת, *thau*, in order to avoid the serpentine sound of that consonant.

Its proper
names pure
Hebrew.

The Chaldaic names of gods, men, places, &c. which occur in Scripture, appear to be no other than Hebrew polished and improved. *Bel*, *Belus* in Latin, is evidently בעל, *Baal*, or we think rather ב-על, *Bechel*. The Phœnicians, and sometimes the Hebrews, used it to signify the Most High. The Chaldeans used their word *Bel* for the same purpose; and because this word originally imported the High One, they dignified their first monarch with that name. They denominated their capital city *Ba-Bel*, which imports the Temple of Bel, and afterwards *Babylon*, which intimates the abode or dwelling of our lord the sun. *Nebo* was a name of the moon amongst the Babylonians, being derived from the Hebrew נבא, *nabah*, *vaticinari*, to prophecy. *Azer* was the planet Mars, from אצר, *Azer* or *Ezur*, *accinxit*, to gird, alluding to the girding on of arms. *Ahad* was an Assyrian name of the sun,[1] being a word deduced from the Hebrew אעד *ahad*, *unus*, one. *Netzur* was the name of an Arabian idol,[2] which often occurs in the composition of Babylonian names. In Arabic it signifies an eagle. We think, however, that the word is the Hebrew נצר, *natzar*, *custodivit*, *servavit*, to keep, to preserve. To these names of deities many more might be added, which the nature of our design will not allow us to mention.

---

[1] *Merob.* lib. i. c. 23.

[2] Pococke, *Specim. Hist. Arab.*

Almost all the Chaldean proper names which occur either in sacred or profane history are evidently of Hebrew original, or cognate with that language. We shall subjoin a few examples. *Nabonassar* is evidently compounded of *Nabo* and *nazur*, both Hebrew words. *Nabopollazar* is made up of *Nabo-Pul*, the same with *Bel*, and *Azer* or *Azor*, above explained. *Belesis* is made of *Bel* and אשא, *Esha*, signifying fire. Nebuchadnezzar, Belshazzar, Belteshazzar, Neriglissar, Nebuzaradan, Rabmag, Rabsaris, Nergal Sharezer, Rabshakeh, Ezarhaddon, Merodach, Evil-Merodach, and numberless others, are so manifestly reducible to Hebrew vocables, when decomposed, that any oriental scholar will readily distinguish them.

Names of places in the Chaldaic are likewise so nearly akin to Hebrew, that nothing but the dialectical tone separates them. Thus *Ur* of the Chaldeans is actually אור, *light*, that city being sacred to the sun; *Sippora* is plainly the Hebrew word *Zipporah; Carchemish*, a city on the Euphrates, is evidently compounded of *Kir* or *Kar*, a city, and *Chemosh*, a name of the sun. In short, every Chaldaic or old Syriac word now extant, betray their Hebrew original without any difficulty. As for their dialectical differences, these may be discovered by consulting the Chaldaic grammars and lexicons.

Phœnician language derived from the Hebrew.

We now proceed to the consideration of the Phœnician language, which is known to have been that of the ancient Canaanites. That this was one of the original dialects, and consequently a cognate of the Hebrew, is universally acknowledged. Instead therefore of endeavouring to prove this position, we may refer our readers to the works of the learned Bochart, where that author has in a manner demonstrated this point, by deriving almost all the names of the Phœnician colonies from the Hebrew, upon the supposition that the dialect of those people was closely connected with that tongue. St. Augustin, in his treatise *de Civitate Dei*, has observed, that even in his time many of the vulgar in the neighbourhood of Carthage and Hippo spoke a dialect of the old Punic which nearly resembled the Hebrew. Procopius, *(de Bello Gothico)* informs us, that even in his days there existed in Africa a pillar with this inscription in Hebrew: "We flee from the face of Joshua the robber, the son of Nun." The names of all the ancient cities built by the Carthagenians upon the coast of Africa are easily reducible to a Hebrew original. The Carthagenian names of persons mentioned in the Greek and Latin history, such as Himilco, Hamilcar, Asdrubal, Hannibal, Hanno, Dido, Anno or Hanno, Sophonisba, Gisgo, Maherbal, Adherbal, and others, all indicate a Hebrew extraction.

The Greeks borrowed a great part of their religious worship from the people of whose language we are treating; and consequently, the names of most of their gods are Phœnician. Almost every one of these is actually Hebrew, as might easily be shown. The names of persons and places mentioned in the fragments of Sanchoniathon, preserved by Eusebius, are all of Hebrew complexion. The names mentioned in the Hebrew Scriptures of places which belonged to the Canaanites prior to the invasion of the Israelites under Joshua, are as much Hebrew as those which were afterwards substituted in their stead. The Punic scene in Plautus has been analysed by Bochart and several other learned men, by whom the language has been clearly proved to be deduced from the Hebrew, with some dialectical variations.

The island of Melita, now Malta, was inhabited by a colony of Phœnicians many ages before the Moors took possession of it. Amongst the vulgar of that island many Punic vocables are current to this day, all which may be readily traced up to the Hebrew source. To these we may add many inscriptions on stones, coins, medals, and the like, which are certainly Phœnician, and as certainly of Hebrew extraction. We have thrown together these few hints without pursuing them to any great length, as we deemed it unnecessary to dwell long on a point so hackneyed and so generally acknowledged.

Origin of the Ethiopians.

Before we proceed to treat of the ancient language of the Ethiopians, we find ourselves obliged to hazard a few strictures touching the origin of that ancient nation. If we can once settle that single point, the discovery will open an avenue to their primitive dialect, the point about which we are chiefly concerned in the present discussion.

In the section concerning the Hebrew language, we were led often to mention the patriarch Cush the eldest son of Ham. The posterity of this family chief, under his son Nimrod, possessed themselves of Shinar, which was afterwards denominated *Chaldæa*. These were probably the Arabians whose kings, according to Eusebius, Africanus, and other ancient chronologers, reigned in Babylon during several successive generations. They were the Cushim or Cushites, whom the learned Mr. Bryant has conducted over a great part of the world, and to whose industry and ingenuity he has ascribed almost all the inventions, arts, sciences, laws, policy, religions, and governments, which distinguished mankind in the earliest ages.

In process of time, the posterity of Chasid or Chesed, called *Chasdim* or *Chasidim*, in the east, and Chaldeans in the west, drove out the Cushim, and seized upon their country. The Cushim retired westward, and spread themselves over that part of Arabia situated towards the south-east. They probably extended themselves over all the eastern part of that peninsula, from the sea to the wilderness between Arabia and Syria, and they were the Ethiopians mentioned in Scripture, by a very unpardonable inadvertency of our translators. Such, then, in our opinion, were the primitive Cushim.

Josephus informs us, that all the Asiatics called the Ethiopians of Africa by the name of *Cushim*.[1] This denomination was not given them without good reason; it imports at least, that they were deemed the descendants of Cush, because it was the constant practice of the orientals in the early ages to denominate nations and tribes from the name of their great patriarch or founder. The name *Cushim* must then have been given to the Ethiopians, from a persuasion that they were the progeny of the son of Ham who bore that name. By what route, however, the Cushim penetrated into that region of Africa which was called by that name, it may be taken for granted that they were the descendants of Cush above mentioned.

It has been observed above, that the posterity of Cush possessed the country of Shinar or Chaldæa at a very early period, but were expelled by the Chasidim or Chaldeans. Upon this catastrophe, or perhaps somewhat later, a colony from the fugitive Cushim transported themselves from the south and south-east coast of Arabia over the sea which lies between that country and Ethiopia. However imperfect the art of navigation might be in that age, the distance was so small that they might easily enough make a voyage across that narrow sea in open boats, or perhaps in canoes. But however that may have been, it cannot be doubted that the tribes on both sides of that branch of the sea were kindred nations.

Their language originally Chaldaic.

If, then, both the northern and southern Cushim sprung from the same stock, there can be no doubt that both spoke the same language. The language of the Babylonian Cushim was Chaldaic, and consequently that of the Ethiopian

---

[1] *Antiq. Judaic.* lib. i. c. 7.

Cushim was the same. We may therefore rest assured, that whatever changes the Ethiopian dialect may have undergone in the course of three thousand years, it was originally either Chaldaic, or at least a branch of that language. Scaliger informs us, that the Ethiopians call themselves Chaldeans; and this, says he, not without reason, because of the many sacred and profane books which are extant amongst them, the most elegant and most beautiful are written in a style resembling that of the Chaldean or Assyrian. Marianus Victorius, who was the first that reduced the Ethiopic tongue to the rules of grammar, tells us, in his *Proœmium*, that the Ethiopians call their tongue Chaldaic; that it springs from the Babylonian, and is very like the Hebrew, Syriac, and Arabic; and at the same time, he concludes, that this language may be easily learned by those who are masters of the Hebrew. The learned Bochart, and Bishop Walton in his *Prolegomena*, are clearly of the same opinion.

The vulgar letters of the Ethiopians, according to Diodorus Siculus, were the same with the sacred characters[1] of the Egyptians.[2] From this account, if the Sicilian may be trusted, the sacred letters of these people, concerning which so many vague conjectures have been formed, were actually Chaldaic. To carry on this investigation a little farther, we may observe, that Sir William Jones seems to have proved, by very plausible arguments, that the Sanscrit characters were deduced from the Chaldaic. This circumstance affords a presumption that the Ethiopian Cushim were likewise concerned with the Egyptians; who, as is remarked in the section concerning the *Sanscrit*, probably introduced the religion of the Brahmans into Hindostan. This is advanced as a conjecture only; and yet when we consider the affinity between the Egyptian and the Gentoo religions, we are strongly inclined to believe that this surmise may one day be verified by undeniable facts.

A ent in- te urse be een th Ethio- pi and E tians.

The original Ethiopians were a highly civilized people; and their laws, their institutions, and especially their religion, were celebrated far and wide. Homer talks in raptures of the piety of the Ethiopians, and sends his gods every now and then to revel twelve days with that devout people. The Sicilian produces a number of very specious arguments to prove that these two nations originally sprung from the same stock. He mentions a similarity of features, of manners, of customs, of laws, of letters, of the fabrication of statues, and of religion, as evidences of the relation between these two neighbouring nations. There was, as everybody knows, a communion, in regard to sacred rites, between the two countries. The Egyptians sent annually a deputation of their priests, furnished with the portable statues of their gods, to visit the fanes of the devout Ethiopians. Upon this occasion, a solemn religious banquet was prepared, which lasted twelve days, and of which the priests of both nations were partakers. It was a kind of sacramental institution, we imagine, by which both parties publicly avouched their agreement in the ceremonies of their religion respectively. These observations plainly show, that the most ancient Ethiopians were a people highly civilized; indeed so much, that the Egyptians were at one time contented to be their scholars. The tone of their language was certainly the same with that of the Chaldeans or Arabian Cushim, from whom they are descended. We know not whether there are any books in the ancient Ethiopic now extant; so that it is not easy to produce instances of its coincidence with the Chaldaic. But Diogenes Laertius[3] informs us, that Thrasyllus, in his catalogue of the books composed by Democritus, mentions one, περι των ἐν Μεροῃ ἱερων γραμματων, concerning the sacred letters in the island of Meroe;[4] and another concerning the sacred letters in Babylon. Had these books survived the ravages of time, they would, in this age of research and curiosity, have determined not only the point under our consideration, but likewise the affinity of sacred rites amongst the Chaldeans, Ethiopians, and Egyptians.

Modern Ethiopic tongues.

We have now shown that the Ethiopians were a colony of Cushites; that the Cushites were originally sovereigns of Shinar or Chaldea, and consequently spoke either Chaldaic, or a dialect of that tongue; that their colonists must have used the same language; and that the ancient Ethiopians were a people highly polished, and celebrated in the most early ages on account of their virtue and piety. It has likewise appeared that the common letters of that people were the sacred characters of the Egyptians. These letters, we imagine, were the Cuphic; for some account of which see the section on the Arabic. When they were discarded, and the modern letters substituted in their room, cannot be determined; nor is it, we apprehend, a matter of much importance. We shall therefore drop that part of the subject, and refer our curious and inquisitive readers to the very learned Job Ludolf's excellent grammar and dictionary of the Abyssinian or Geez tongue,[5] where they will find every thing worth knowing on that subject. We shall endeavour to gratify our readers with a very brief account of the modern Ethiopic or Abyssinian tongue; for which we are principally indebted to that learned, indefatigable, and adventurous traveller, Bruce; who, by his observations on that country, which he made in person, often at the hazard of his life, has discovered, as it were, a new world both to Europe and Asia.

The most ancient language of Ethiopia, which we shall now call by its modern name of Abyssinia, was, according to that gentleman, the *Geez*, which was spoken by the ancient Cushite shepherds. This, we should think, approaches nearest to the old Chaldaic. Upon a revolution in Habesh, the court resided many years in the province of Amhara, where the people spoke a different language, or at least a very different dialect of the same language. During this interval, the Geez, or language of the shepherds, was dropped, and retained only in writing, as a dead language; the sacred Scriptures being in that tongue only saved it from going into disuse. This dialect is exceedingly harsh and unharmonious. It is full of the letters, D and T, on which an accent is put that nearly resembles stammering. Considering the small extent of sea which divides this country from Arabia, we need not wonder that it has great affinity with the Arabic. It is not difficult to be acquired by those who understand any other of the oriental languages; and as the roots of many Hebrew words are only to be found here, it seems to be absolutely necessary to all those who wish to obtain a critical skill in that language.

Ethiopic alphabet.

The Ethiopic alphabet consists of twenty-six letters, each of which, by a *virgula* or point annexed, varies its sound in such a manner as that those twenty-six form as it were sixty-two distinct letters. At first they had only twenty-five of these original letters, the Latin P being wanting; so that they were obliged to substitute another letter in its place. *Paulus*, for example, they call *Taulus*, *Aulus*, or *Caulus*, and *Petros* they pronounced *Ketros*. At last they substituted T, and added this to the end of their alphabet; giving it the force of P, though it was really a repetition of an old character, rather than the invention of a new one. Besides these, there are twenty others of the nature of diphthongs; though some of them are probably not of the same antiquity with the letters of the alphabet, but have been invented by the scribes in later times for the sake of convenience.

---

[1] Lib. iii. p. 101, *Steph.*

[2] We find the same observation confirmed by Heliodorus (*Ethiopica*, lib. x. p. 476.) "The royal letters of the Ethiopians," says he, "were the sacred characters of the Egyptians." Cassiodorus likewise assures us, "that the letters inscribed upon the Egyptian obelisks were Chaldean." But recent discoveries have refuted these and other similar statements.

[3] Lib. ix. p. 461. *Causaubon.*

[4] Where the capital of Ethiopia was situated.

[5] A very learned German, who published a grammar and dictionary of the Geez in folio.

The Amharic, during the long banishment of the royal family in Shoa, became the language of the court, and seven new characters were of necessity added to answer the pronunciation of this new language; but no book was ever written in any other language than Geez. There is an old law in the country, handed down by tradition, that whoever shall attempt to translate the Holy Scripture into Amharic, or any other language, his throat shall be cut after the manner in which they kill sheep, his family sold to slavery, and his house razed to the ground.

Before we leave this subject, we may further observe, that all the ancients, both poets and historians, talk of a double race of Ethiopians; one in India, and another in Africa. What can have given rise to this opinion, it is not easy to discover. Perhaps the swarthy complexion of both people may have led them to entertain this opinion. Eusebius indeed informs us,[1] that "a numerous colony of people emigrated from the banks of the Indus, and, crossing the ocean, fixed their residence in the country now called Ethiopia." For our part, we are rather inclined to believe, that the original Ethiopians transported themselves into India, and there perhaps co-operated with the Egyptians in digging the excavations, and framing the statues, some of which are still to be seen in that country, and which we have mentioned in another section of this article. The Greeks called those people Αιθιοπες, *Æthiopes*, we believe from their sun-burned countenances; but indeed they were very little acquainted either with the country or its inhabitants.

Ancient language of Egypt a sister dialect of Hebrew.

The most ancient name of Egypt was *Mizraim*, and consequently the Arabians still call it *Mesri*. It was likewise distinguished by other names, such as *Oceana*, *Aeria*, &c. It appears from the sacred historian, that it was inhabited by the descendants of Mizraim, the second son of Ham. Mizraim had several sons, who, according to the Scriptural account, settled respectively in that country. If we trust to the sacred records, there will be little difficulty in ascertaining the language of the Mizraim. It will appear to have been one of the sister dialects of the Hebrew, Phœnician, Arabic, and Chaldaic. But the origin of the Egyptian people, their language, religion, laws, and institutions, have been so warped and confounded, both by their own historians and by those of other countries, that one is scarcely able to determine what to believe or what to reject. Herodotus, Diodorus Siculus, Strabo, Ptolemy, and most other ancient geographers and historians, are universally agreed, that Egypt, at least that part of it called the *Delta*, was overflown by the sea, and consequently uninhabitable for many centuries after the dispersion of mankind. When we consider the low situation of the Delta, and the violent current of the tide from the coast of Phœnicia and Palestine towards that shore, we would be almost tempted to adopt this hypothesis; but the sacred records avouch the contrary. According to them, Egypt was a populous, rich, and flourishing kingdom, as early as the age of Abraham. But if Lower Egypt had been a stagnant marsh at any time after the general deluge, it could scarcely have been drained, cleared, cultivated, and stocked with inhabitants, as early as the days of Abraham.

Diodorus Siculus, however, is positive that the Egyptians were a colony of Ethiopians;[2] and this he endeavours to prove by the similarity of features, customs, laws, and religious ceremonies, between the two nations. That there was a constant intercourse of good offices between these two branches of the Hamites, cannot be questioned; and that they nearly resembled each other in many respects, is too evident to admit of contradiction. The excavations, originally dug out of the solid rocks of porphyry and marble, in which the natives resided before the plains were drained, have been observed by many judicious travellers,[3] who, having visited that region in modern times, are generally of opinion that the land has gained nothing on the sea since the period when Herodotus wrote his description of that country; and from this circumstance we may conclude, that the idea of the inundation of the Delta is not founded in fact.[4]

But even admitting that the Egyptian Delta has acquired nothing from the sea since the age of Herodotus to the present, it certainly does not follow that the region in question was never overflowed; since there are in many parts of the globe, large tracts of land, certainly once covered with sea, which have continued to this day in the very same situation in which they were two thousand years ago. The decision of this point, however, we leave to the judgment of our readers.

We have already hinted our opinion of the nature of the Egyptian language; but because Egypt is generally thought to have been the native land of hieroglyphics, and because many are of opinion that hieroglyphical characters were prior to alphabetical, we shall hazard a few conjectures respecting that species of writing.

Egyptian hieroglyphics.

The end of speech, in general, is to enable men to communicate their thoughts and conceptions to one another when present; and the use of writing is to perform the same office when people are at so great a distance that vocal sounds cannot mutually reach them. Hieroglyphics are said to have been invented to supply this defect.[5] The most ancient languages were everywhere full of tropes and figures borrowed from sensible objects. As in that stage of society men have not learned to abstract and generalize, all their ideas are borrowed from such objects as most forcibly strike their senses. This circumstance would naturally suggest to savages the idea of conveying their sentiments to each other, when absent, by delineations of corporeal objects. Thus, if a savage asked a loan of his friend's horse, he might find means to have conveyed to him the figure of that animal; and so of other things. This was the very lowest species of graphic communication, and has been styled picture-writing.

But necessity would soon impel our savage correspondents to fabricate a method more extensively useful, which would likewise be suggested by the constant use of the metaphorical mode of speech. Some savage leader, more sagacious than the vulgar herd, would observe that certain sensible objects were fitted, according to the rules of analogy, to represent certain human passions, and even some abstract ideas; and this notion would readily enough be adopted by the many as a new improvement. In this case a *horn* might be the emblem of *power*, a *sword* of *bravery*, a *lion* of *fury*, a *fox* of *cunning*, a *serpent* of *malice*, and so on. By and by artificial signs might be contrived to express such ideas as could not readily be denoted by bodily objects; and this might be called symbolical writing. Such was the foundation of the Chinese characters; and hence the prodigious number of characters of which the written language of that people is composed. Farther they could not proceed, notwithstanding their boasted inventive powers; and farther, we believe, no nation ever did proceed, who had once upon a time no other characters but hieroglyphics. The Mexicans had arrived at the very lowest stage of hieroglyphical writing, but had not taken one step towards alphabetical. The Hurons employed hieroglyphical symbols, but never entertained a single idea of alphabetical. Hieroglyphical characters are the images of objects conveyed to the mind by the organs of vision; alphabetical are arbitrary artificial marks of sound, accommodated by compact to convey to the mind the ideas of objects by the organs of hearing. In a word, we think that there is not the least analogy between these two species to conduct us from the one to the other; and we are therefore of opinion, that hieroglyphical characters were never the vulgar channels of conveyance amongst civilized people.

[3] See Bruce's Travels. vol. i.

[4] Mr. Bruce, Dr. Shaw, Bishop Pococke, Savary, Volney, &c.

[5] It is necessary here to remind our readers, that this article was originally written long before any insight had been obtained into the real nature of the Egyptian methods of writing, by means of the discoveries of Young, Champollion, and others; and that consequently, in as far as relates to the subject of hieroglyphics, many of the author's opinions and conclusions would, in the actual state of our knowledge, require important modifications. But having been induced to reprint it, in consequence of the great learning, research, and ingenuity it displays, we have not conceived it necessary to expunge this defective portion of it; deeming it sufficient to refer the reader for the most recent information to the article Hieroglyphics, and believing that it would even be interesting to compare the opinions entertained by the most learned men of the last generation, with the results which have been obtained from more auspicious and fortunate investigations, in our own day.

We know that in this point we differ from many learned, judicious, and ingenious writers, some of whom have taken much pains to investigate the intermediate stages through which the fabricators of characters must have passed in their progress from hieroglyphical to alphabetical writing. These authors have adopted a plan analogous to Bishop Wilkins' project of an artificial language. In this theory, we own, we were led to suspect that they supposed all mankind were once upon a time savages, and were left to hammer out words, as well as characters, by necessity, ingenuity, experience, or accident. For our part, we have endeavoured to prove, in the section on the Hebrew language, that alphabetical writing was an antediluvian invention; and we have now to state it as our opinion, that amongst all those nations which settled near the centre of civilization, hieroglyphics were comparatively a modern fabrication.

The Orientals are, at this day, extravagantly devoted to allegory and fiction. Plain unadorned truth has to them no charms. Hence that extravagant medley of fables and romance with which all antiquity is replete, and by which all ancient history is disfigured and corrupted. Every doctrine of religion, every precept of morality, was tendered to mankind in parables and proverbs. Hence Scripture speaks of understanding a proverb, the words of the wise, and their dark sayings. The eastern sages involved their maxims in this enigmatical dress for several reasons. They wished to fix the attention of their disciples, to assist their memory, to gratify their allegorical taste, to sharpen their wit and exercise their judgment, and sometimes perhaps to display their own acuteness, ingenuity, and invention. It was amongst the ancients an universal opinion, that the most sacred arcana of religion, morality, and the sublime sciences, were not to be communicated to the uninitiated rabble. For this reason every thing sacred was involved in allegorical mystery.

Here, then, we ought to look for the origin of hieroglyphical or picture-writing amongst the civilized nations of the East. They did not employ that species of writing because they were ignorant of alphabetical characters, but because they thought fit to conceal the most important heads of their doctrines under hieroglyphical figures. The Egyptian priests were most celebrated for their skill in devising those emblematical representations; but other nations likewise employed them. We learn from the fragments of Berosus the Chaldean historian, preserved by Syncellus and Alexander Polyhistor, that the walls of the temple of Belus at Babylon were covered all over with such emblematical paintings. These characters were called ἱεροι, because they were chiefly employed to represent sacred objects; and γλυφικα, because they were originally carved or engraved. Their name points to their original use.[1]

From the above deduction we would conclude, that this species of writing was an adventitious mode in Egypt, peculiar to the priests, and employed chiefly to exhibit things sacred; and that amongst all civilized people it did not supersede the use of alphabetical characters, nor did the use of the latter originate from the former. When alphabetical letters were invented, if indeed they were a human invention, they were antecedent to the other in use and in extent. The Egyptian priests alone knew the true import of those sacred symbols; and communicated that knowledge first to their own children from generation to generation, then to the initiated, and last of all to the grandees of the nation, all of whom were indeed initiated. The hieroglyphics of Egypt were not then the symbols of any sacred occult language, but signs invented by the priests, and prophets or wise men, in order to represent their deities, the attributes and perfections of their gods, the mysteries of their religion, and many other circumstances relating to objects of importance, which were deemed either too sacred or too important to be imparted to the vulgar.

The Egyptians ascribed the invention of letters to a person whom they called *Thoth*, *Theuth* or *Thyoth*,[2] the Greeks Ἑρμης, and the Romans *Mercurius*. Plato calls him a god, or a godlike man;[3] Diodorus makes him privy counsellor to Osiris;[4] Sanchoniathon connects him with the Phœnician Kronos or Saturn.[5] To this Mercury the Egyptians ascribe the invention of all the arts and sciences. He was probably some very eminent inventive genius, who flourished during the first ages of the Egyptian monarchy, and who perhaps taught the rude savages the art of writing.

Two kinds of alphabetical characters in Egypt.

According to Diodorus Siculus, the Egyptians had two kinds of letters;[6] the one sacred, the other common. The former the priests taught their own children, the latter all learned promiscuously. In the sacred characters the rites and ceremonies of their religion were couched; the other sort of writing was accommodated to the ordinary business of life. Clemens Alexandrinus mentions three different styles of writing employed by the Egyptians.[7] "The pupils, who were instructed by the Egyptians, first learned the order and arrangement of the Egyptian letters, which is called *epistolographic*, that is, the manner of writing letters; next, the hieratic character, which the sacred scribes employed; lastly, the hieroglyphic character, one part of which is expressed by the first elements, and is called *cyriologic* or *capital*, and the other *symbolic*. Of the symbolic kind, one part explains properly by imitation; and the other is written tropically, that is, in tropes and figures; and a third by certain enigmatical expressions. Accordingly, when we intend to write the word *sun*, we describe a circle; and when the moon, the figure of the planet appearing horned, conformably to the appearance of that luminary after the change." In this passage we have an excellent description of the three different modes of writing used by the Egyptians; the common, the sacred, and the hieroglyphic. The last Clemens describes according to its three divisions, in exact conformity to our preceding observations.

The sacred letters and language of Egypt Chaldaic.

By the description above translated, it plainly appears, that the sacred characters of the Egyptians were entirely different from the hieroglyphic; and by this consideration we are in a great measure justified, in supposing, as we have all along done, that the sacred letters of the Egyptians were actually the Chaldaic. The inscriptions on the obelisks mentioned by Cassiodorus, so often quoted, were certainly engraved in the sacred characters; but if the sacred characters were Chaldaic, the sacred language was probably the same.

---

[1] Instead of pursuing these observations, which the nature of our design will not permit, we must refer our readers to Herodotus, lib. ii. Diodorus Sic. lib. i. Strabo, lib. xvii. Plut. *Isis et Osiris*; and amongst the Christian fathers to Clemens Alexandrinus *Stromata*, and Eusebius *Præparatio Evangelii*, but chiefly to Horus Apollo's *Hieroglyphica*.

[2] Eusebius, *Præp. Evang.* [3] *Phædrus.* [4] Lib. i. [5] *Præp Evang.* Lib. i. [7] *Stromata*, lib. v.

The Egyptians pretended that the Babylonians derived from them the knowledge of the arts and sciences; whilst, on the other hand, the Babylonians maintained, that the Egyptians had been tutored by them. The fact is, they both spoke the same language, used the same religious rites, and had applied with equal success to astrology, astronomy, geometry, arithmetic, and the other sciences; hence there had arisen between the two nations a rivalship, which laid the foundation of these opposite pretensions. The most faithful specimen of the vulgar language of the Egyptians, is, we believe, still preserved in the Coptic, which, however, is so replete with Grecisms, that it must be difficult to trace it out.

Under the Ptolemies, the Greek was the language of the court, and consequently must have diffused itself over a great part of the country. Hence, much of the Coptic consists of Greek words, diversified only by their terminations, declensions, and conjugations. To be convinced of the truth of this, the learned and curious reader need only consult Christian Scholtz's Egyptian and Coptic grammar and dictionary, corrected and published by Godfred Woide, Oxford, 1788.

The Egyptians and Phœnician languages the same.

The Egyptians and Phœnicians were in a manner cousins-german, and consequently must have spoken the same language; that is, one of the sister dialects of the Hebrew, Chaldean, Arabian, Cushite, and others. This is not a mere conjecture; it may be realized by almost numberless examples. It is true, that when Joseph's brethren went down to Egypt, and that ruler deigned to converse with them, they could not understand the Egyptian idiom which he spoke; nor would he, had he been actually an Egyptian, have understood them without an interpreter. The only conclusion from this circumstance is, that by the time in question the Egyptian had deviated considerably from the original language of mankind. The Irish and Welch, every body knows, are only different dialects of the Celtic tongue; and yet experience proves, that a native of Ireland and another of Wales, cannot well comprehend each other's language, nor converse intelligibly without an interpreter. The Gaelic spoken in the Highlands of Scotland, and the Irish, are known to be both branches of the old Celtic; yet a Scotch Highlander and an Irishman can scarcely understand each other's speech. By a parity of reason, a Hebrew and an Egyptian might, in the age of Joseph, speak only different dialects of the same original tongue, and yet find it difficult to understand each other. The fact seems to be, the Hebrew dialect had been in a manner stationary, from the migration of Abraham to that period; whereas the Egyptian, being spoken by a powerful, civilized, and highly cultivated people, must have received many improvements, perhaps additions, in the course of nearly two centuries.

The vulgar letters of Egypt.

The descendants of Canaan and of Mizraim were strictly connected in their religious ceremonies. They worshipped the same objects, namely, the host of Heaven; they mourned for Osiris and Adonis in concert; they carried on a joint commerce, and, as we think, spoke the same language. We may therefore conclude, that their vulgar letters were nearly the same, both in form, in disposition, and in number. Their original number was probably sixteen, viz. five vowels, six mutes, simple and middle, four liquids, and the solitary σ. With these, it is likely, was joined a mark of aspiration, or an *h*, such as we have in the Roman alphabet, and find on some Greek monuments. Cadmus was originally an Egyptian; and that leader brought a new set of letters into Greece. These are generally deemed Phœnician. But they were nearly the same with the ancient Pelasgic, as will be shown in the section on the Greek language. The latter, we think, were from Egypt, and consequently the former must have been from the same region. Danaus, Perseus, Lelex, and others were of Egyptian extraction; and they too adopted the Cadmean characters, without substituting any of their own.

The Jonim or Ionians, emigrated from Gaza, an Egyptian colony; and their letters are known to have differed very little from those of Cadmus and the Pelasgians. The conclusion therefore is, that the vulgar Egyptian letters were the same with the Phœnician.

We are abundantly sensible that there are found upon Egyptian monuments characters altogether different from those which we have here been describing. At what time, by what people, and to what language these letters belonged, we will not pretend to determine. The Ethiopians, the Chaldeans, the Persians, the Greeks, the Romans, and the Saracens, have at different times been sovereigns of that unhappy country; and other nations, whose memory is now buried in oblivion, may have erected monuments, and covered them with inscriptions composed of words taken from different languages, and whimsically devised, with a view to perplex the curious antiquaries of future ages. Some of these are composed of hieroglyphics intermingled with alphabetical characters, artificially disarranged, in order to render them unintelligible; but we do not pretend to develope such texts, because the most inquisitive and sagacious antiquaries are not yet agreed as to their purport and signification.[1]

Egyptian names of Hebrew origin and signification.

We shall now proceed to show, that most part of the names of persons and places which have been conveyed down to us, may, in general, be reduced to a Hebrew, Phœnician, Syrian, or Chaldean original. As the first of these languages is most generally known, we shall therefore employ it as our arch-type or standard, and begin with those terms which occur in Scripture.

The word *Pharaoh*, the title of the *melech* or king of Egypt, is, we think, compounded of two terms, which plainly discover a Hebrew original. According to an oriental tradition, the first who assumed this title was the sovereign of the Hycshos or Royal Shepherds, a race of people from Arabia and Phœnicia. At an early period they conquered Egypt, and kept possession of that country for several centuries. They gloried in the title of ὑκσοι or ὑκουσοι, which according to Josephus, *(contra Apion.)* signifies royal shepherds. The word *Pharaoh*, seems to be compounded of פר *Phar*, a bullock, and רעה, *Rachah*, to feed; hence we think it ought to be written פרעת, *Pharachah*.[2] The name given to Joseph is evidently of kin with the Hebrew; for *zaphnath* differs very little from the Hebrew verb *tzaphan*, which signifies to hide, to keep secret, and *paneah* or *phaneah*, signifies much the same with the Hebrew *phanah*, *aspexit*; so that the name actually intimates one who sees hidden things, which was certainly the very idea the prince intended to be conveyed by giving him that name.[3]

---

[1] This, though no longer applicable, was strictly true at the time when the above article was written.

[2] This, we think, is a mistake. The word written *Pharaoh* in Hebrew, was written *Phra* in Egyptian, and is composed of *Ra*, signifying the *sun*, and the ordinary prefix *Ph*, signifying *of* or *from*; so that *Phra*, or, by the insertion of a vowel, *Phara*, means *of the sun*, or *descended of the sun*. Hence the word *Pharaoh* is not a proper name, but a generic term applicable to all the kings of Egypt, from the time of Rhameses to the extinction of the last dynasty of native sovereigns.

[3] For the true explanation of this name, *Zaphnathpaneah*, see the section of the article HIEROGLYPHICS, which treats of the Coptic language.

Potiphar or *Potipherah*, the name of Joseph's father-in-law, has likewise a dialectical affinity with the Hebrew idiom. In that language *patah* signifies to open, to explain, which was one part of the sacerdotal office, and *phar* imports a bullock.[1] Potiphar was then priest of the bullock, that is, the ox, *apis*, sacred to the *sun.*[2] This person was priest or prince of On, which, according to Cyrillus on Hosea, was an Egyptian name of that luminary. The Hebrew word *hon* or *chon*, signifies power, wealth, sufficiency; a very proper epithet for the Sun, who was thought to bestow those blessings. The name of Joseph's wife was *Asenath*, or *Asnath*, compounded of *ishah*, a woman, and *Naith* or *Neith*, an Egyptian name of Minerva, a votary of Minerva.

Almost all the names of cities belonging to Egypt which are mentioned in Scripture are evidently Hebrew. To be satisfied as to this position, the curious reader may consult Jamieson's *Spicilegia*, an excellent book, though very little known. The names of most of the Egyptian deities are significant in the Hebrew tongue; and in that dialect these names appear to have been imposed with great judgment and propriety, all of them plainly indicating some office assigned them, or pointing to some peculiar attribute. We shall produce a few instances.

Osiris was the great divinity of Egypt, and he was certainly the Sun. The Egyptians gave their deities a variety of names in allusion to their various offices and attributes. Jablonski has in a manner wearied himself with tracing the signification of this name. In Hebrew we have *oshir*, to grow rich, to be enriched. The sun may be called the great enricher of nature, and therefore might properly be called by a name alluding to that quality. Isis was both the moon and the earth. *Ishah* is the Hebrew word for *woman*, and Horus Apollo assigns this very derivation. Anubis was one of the names of Mercury amongst the Egyptians, and he was always represented with the head of a dog. He accompanied Isis in her peregrinations in quest of Osiris, and frightened away the wild beasts from attacking the princess. In Hebrew, *nubah* signifies to bark. Here then the analogy is, we think, evident. Many Egyptian names begin with *Can*, such as Canobus, Canopus, &c. The Hebrew word *cahen* or *cohen*, in Syriac *con* or *chon*, intimates both a prince and a priest. *Ob* or *aub*, in Hebrew, imports a bottle, a flaggon, any thing round and prominent like the human belly. In the language of Egypt it was often applied to the sun, in allusion to his rotundity. In the temple of Jupiter Ammon or Amon, in the desert of Libya, there was a statue of the god representing the navel of the human body, which was probably framed in allusion to this fancy. Hence the Pythoness, or people who, according to the Scripture, had familiar spirits, were said to prophecy by the inspiration of Ob, as the Delphic priestess did by that of Apollo. Again, many Egyptian names end with *siris*, as Busiris, Calasiris, Termosiris. This termination is no doubt a cognate of the Hebrew and Chaldean *sar* or *zar*, signifying a prince, or grandee. The river Nile in the Ethiopian dialect is denominated *Siris;* that is, we believe, the king of rivers. The same stream seems to derive the name by which it is generally known, from the Hebrew *nehel*, a valley, or a torrent running down a valley. The same river was often called *oceanus*, a word composed of *og*, *oc*, or *och*, which signifies a king, a leader, and the Hebrew *oin*, a fountain; so that the word imports the king of fountains. The Hebrews always denominated the land of Egypt the land of Mizraim; and the Egyptians themselves, in later times, appear to have called it ’Αιγυπτος, *Ægyptus*, which some think is compounded of *ai*, signifying in Hebrew an island, a country, a province, and *Copt* or *Cupt*, a famous city in that country.[3]

From these specimens, we hope it will appear that the Egyptian language in the more early ages was one of those dialects into which that of the descendants of the postdiluvian patriarchs was divided, and perhaps subdivided, a few centuries after the deluge. Amongst all these, we believe, such an affinity will be found, as plainly demonstrates that they originally sprung from one common stock. Besides, we might easily follow the Egyptian language into Greece, and there trace a great number of Egyptian terms transplanted into Greek; a task, however, which the nature of this inquiry will not permit. If our learned readers should incline to know more of the affinity of the Egyptian tongue with the others so often mentioned, they may consult Bochart's *Chanaan*, Walton's *Prolegomena*, Gebelin's *Monde Primitif*, Jamieson's *Spicilegia*, and other works.

SECT. IV. OF THE PERSIAN LANGUAGE.

The Persian language is divided into the ancient and modern. The former of these is now very imperfectly known; the latter is one of the most expressive, and at the same time one of the most highly polished, in the world. In treating of this language, we shall, in compliance with the plan we have all along followed, begin with the ancient.

At the birth of Mohammed two languages prevailed in Persia.

When Mohammed was born, and Anúshíraván, whom he calls the just king, sat on the throne of Persia, two languages were generally prevalent in that empire.[3] The one called *Deree*, was the dialect of the court, being only a refined and elegant branch of the *Parsee*, so called from the province of which Shiraz is now the capital; and the other, being that of the learned, in which most books were composed, had received the name of *Pahlavi*, either from the heroes who spoke it in former times, or from *pahlu*, a tract of land which included some considerable cities of Iran. The ruder dialects of both were spoken by the rustics of several provinces; and many of these distinct idioms were vernacular, as happens in every kingdom of considerable extent. Besides the Parsee and Pahlavi, a very ancient and abstruse tongue was known to the priests and philosophers, called the language of the *Zend*, because a book on religious and moral duties which they held sacred, and which bore that name, had been written in it; whilst the *Pazend* or commentary on that work was composed in Pahlavi, as a more popular dialect. The letters of this book were called *zend*, and the language *avesta*.

The Zend and the old Pahlavi are now almost extinct in Iran, and very few even of the Guebres can read it; whilst the Parsee remaining almost pure in the *Shah-nameh*, has, by the intermixture of Arabic words, and many imperceptible changes, now become a new language, exquisitely polished by a series of fine writers both in prose and verse, analogous to the different idioms gradually formed in Europe after the subversion of the Roman empire.

Parsee language.

The learned and indefatigable Sir William Jones is confident that the Parsee abounds with Sanscrit words, which have undergone no other change than such as may be observed in the numerous dialects of India; that many Persian imperatives are the roots of Sanscrit verbs; and that even the moods and tenses of the Persian verb substantive, which is the model of all the rest, are deducible from the Sanscrit by an easy and obvious analogy. From all this he infers that the Parsee, like the various idiomatic dialects, is derived from the language of the Brahmins. But the conclusion is, we imagine, not altogether just, since by the same train of reasoning we may infer that the Sanscrit is derived from the Parsee. The same learned gentleman adds, that the multitude of compounds in the Persian language proves that it is not of Arabian but Indian origin. This is undoubtedly true; but though the Parsee is not of Arabian, it does not necessarily follow that it is of Sanscrit origin. It might with the same propriety, and with an equal show of reason, be concluded, that the Greek language is descended of the Sanscrit, because it too abounds with compounds. We may then rest assured, that neither the one nor the other argument adduced by the ingenious president proves that the Parsee is a descendant of the Sanscrit.

---

[1] The fact is, *Potiphar*, in Egyptian *Puti-phré*, means *priest of the sun*, from *puti*, priest, and *ra* or *re*, the sun, with the prefix *ph*, signifying *of.*

[2] The Septuagint, (Gen. xli. 45, 50,) translate *On* by ‘Ηλιοπολις.

[3] For the true mythology of ’Αιγυπτος, *Ægyptus*, see the article EGYPT, *sub initio.*

[4] The moderns call the empire of Persia *Iran*, a name unknown to the ancients.

The Pahlahvi.

The same illustrious scholar assures us, that the Zend bears a strong resemblance to the Sanscrit; which, however, it might do without being actually derived from it, since we believe every oriental scholar will find that all the languages from the Mediterranean to the utmost coast of Hindustan exhibit very strong indications of a common origin. The Parsee, however, not being the original dialect of Iran or Persia, we shall not pursue it farther at present, but proceed to give some account of the Pahlavi, which was probably the primitive language of the country. We have observed, above, that the Pazend or commentary on the Zend was composed for the use of the vulgar in the Pahlavi, which, according to Sir William Jones, was a dialect of the Chaldaic; an assertion of which he exhibits the following proof.

From the nature of the Chaldean tongue, most words ended in the first long vowel, like *shemaiá*, heaven; and that very word, unaltered in a single letter, we find in the Pazend, together with *lailiá*, night, *meyá*, water, *nírá*, fire, *matrá*, rain, and a multitude of others, all Arabic or Hebrew, with a Chaldean termination. In like manner, *zamar*, by a beautiful metaphor from pruning trees, means in Hebrew to compose verses, and thence, by an easy transition, to sing them; but in Pahlavi we find the verb *zamarúniten*, to sing, with its forms *zamaraunemi*, I sing, and *zamzunid*, he sang, the verbal terminations of the Persian being added to the Chaldaic root. All these words are integral parts of the language, and not adventitious like the Arabic nouns and verbals engrafted on the modern Persian.

From this reasoning it plainly appears, firstly, that Pahlavi was the ancient language of Persia; and, secondly, that the ancient Persian was a cognate dialect of the Chaldean, Hebrew, Arabic, Phœnician, &c. M. Anquetil has annexed to his translation of the *Zendavesta* two vocabularies in Zend and Pahlavi, which he found in an approved collection of *Rawayat* or traditional pieces in modern Persian. His vocabulary of the Pahlavi strongly confirms this opinion concerning the Chaldaic origin of that language. But with respect to the Zend, it abounded with numbers of pure Sanscrit words, to such a degree, indeed, that six or seven words in ten belonged to that language.

Pahlavi derived from Chaldaic and Sanscrit.

From this deduction it would appear, that the oldest languages of Persia were Chaldaic and Sanscrit, and that when they had ceased to be vernacular, the Pahlavi and Zend were deduced from them respectively, and the Parsee either from the Zend, or immediately from the dialect of the Brahmins; but all had perhaps a mixture of the Tartarian, for the best lexicographers assert, that numberless words in ancient Persian are taken from the Cimmerians. With respect to the last of these, we cannot help being of opinion, that colonies of people from the neighbourhood of Persia had transported themselves into Crim Tartary, and perhaps into Europe, and that these colonists brought along with them those terms which still occur in their dialect. Emigrants from the same region must have found their way into Scandinavia, since numberless Persian words are still current in those regions. Perhaps Odin and his followers emigrated from the neighbourhood of Media and Persia, and brought with them the dialect of the nations from whose country they had taken their departure.

The Zend from the same source.

With respect to the Zend, it might well be considered as a dialect of the Sanscrit; it was probably a sacred language, and if so, concealed from the vulgar, and reserved for the offices of religion. If Zoroastres, or Zaratusht as the Orientals call him, travelled into Egypt, and was initiated in the mysteries of the Egyptian religion, as some pretend that he was, he might have been instructed in the sacred dialect of that people by the priests under whom he studied; and when he returned into Persia, and became the apostle of a new religion, he might have composed the volume of his laws and religious institutions in the sacred language of his Egyptian tutors. This language then became that of the Magi, who concealed it carefully from the knowledge of the uninitiated, as the priests did in Egypt and the Brahmins in Hindustan.

In the section on the Sanscrit language, we shall give a detail of a number of particulars, which to us seem to furnish a presumption that the language in question was imported from Egypt into Hindustan. We confess there are not sufficient data to improve these presumptions into absolute certainty; but we hope the time is not very distant when the members of the Asiatic Society will discover abundant materials to ascertain the truth of this position. We are the rather inclined to adopt this hypothesis, when we consider the character of Zoroastres in connection with that of the Egyptian Cohens and of the Indian Brahmins. . .

If this opinion should one day prove to be well-founded, we believe that the coincidence between the language of the Zend and the Sanscrit will be easily accounted for, without making the Hindus masters of Iran or Persia, and then driving them back to the shores of the Ganges. That the nations of Turan or Scythia did actually overrun that country, and make themselves masters of a considerable part of it at different times, is vouched by the records and traditions of the Persians themselves; and upon those occasions a number of Tartarian words might be introduced into the country, and acquire a currency amongst the inhabitants. But as the annals of ancient Persia have long since been destroyed, it is impossible to ascertain either the extent or duration of these irruptions; indeed the nature of our design does not call for or admit such investigation.

Proofs from Scripture of the origin of the Pahlavi.

In order to corroborate the cognation between the Chaldaic and the Pahlavi languages, we shall subjoin a few arguments derived from the Mosaic history, and the other writings of the Old Testament. These, we believe, will be admitted as irrefragable proofs of the position above advanced, by such as admit the authenticity of the sacred records.

Elam is generally allowed to have been the progenitor of the Persians. This patriarch was the eldest son of Shem who was the son of Noah; and according to the Mosaic account, his posterity settled in the neighbourhood of the descendants of Ashur, Arphaxad, Lud, and Aram, the other sons of Shem. The country where they settled was denominated *Elymais*,[1] as late as the beginning of the Christian era; and this name was retained until the Saracens conquered and took possession of that country. If such was the case, then the Elamites or Persians must have spoken a dialect of the primary language, which, in the first section of this article, we proved to have been the Hebrew.

When the four eastern monarchs invaded the five cities of the plain in Canaan,[2] Chedorlaomer king of Elam was at the head of the confederacy; Amraphel king of Shinar, that is, of Babylon or Chaldea, was one of the allies; Arioch king of Elasar was another; and Tidal, king of some scattered nations in the same neighbourhood, was the fourth. That Chedorlaomer was the principal in this expedition, is obvious from the historian's detail of the second, where that prince is placed first, and the rest are named "the kings that were with him." This passage likewise demonstrates, that Elam, Shinar, and Elasar, lay contiguous, and were engaged in the same cause. Wherever the country in question is mentioned in Scripture prior to the era of Daniel and Ezra, it is always under the name of Elam. To go about to prove this would be superfluous.

---

[1] *Strabo*, lib. ii.

[2] Gen. xiv.

According to Xenophon,[1] the Persians knew nothing of horsemanship before the age of Cyrus; but the same historian informs us, that after that monarch had introduced the practice of fighting on horseback, they became so fond of it, that no man of rank would deign to fight on foot. Here it ought to be considered, that this historian was now writing a moral, military, and political romance, and therefore introduced this anecdote, in order to exalt the character of his hero; so that we are not to suppose that the people in question were unacquainted with the art of equitation until that period.

The very name *Phars* or *Pharas* is certainly of Hebrew origin, and alludes to the skill that people professed in horsemanship. The original seems to be *pharsah*, *ungula*, a hoof; and in the Arabic *pharas* intimates a horse, and *pharis* a horseman. Consequently the people were denominated *Parsai*, and the country *Pars*, because they were trained from their infancy to ride the great horse, which indeed they deemed their greatest honour. This name was perhaps at first imposed upon them by the neighbouring nations, and in process of time became their common gentile appellation. Mithras is generally known to have been the chief divinity of the Persians; a name which is plainly derived from *mither*, great. We find in Strabo the Persian god *Amanus*, which is plainly a cognate of *hamah*, the sun or fire. Hence we believe comes *hamarim*, the hearths or chapels, where the fire sacred to the sun was always kept burning, and which the Greeks called Πυραθεια, or fire temples. Herodotus[2] mentions a custom amongst the Persians, according to which, when they came to engage an enemy, they cast a rope with a kind of gin at the end of it on their enemy, and by this means endeavoured to entangle and draw him into their power. The people of Persia who employed this net or gin were called *Sargates*, from *sarags*, *sherag*, or *serig*, a word which in Hebrew, Arabic, and Chaldaic, signifies to hamper or entangle; and hence perhaps the Greek word Σαργανη, a basket or net. *Sar* or *zar* in Hebrew, Phœnician, and Syriac, signifies a lord, a prince; and hence we have the initial syllable of the far-famed *Zartusht* or Zoroaster. In a word, most of the Persian names that occur in the Grecian histories, notwithstanding the scandalous manner in which they have been disguised and metamorphosed by the Greeks, may still with a little skill and industry be traced back to a Hebrew, Chaldaic, Syriac, or Phœnician origin. In the books of Daniel, Ezra, Nehemiah, and Esther, we find a number of Persian names which are all of a Hebrew or a Chaldaic complexion. But to investigate these at much greater length would be foreign to the design of the present article; though, if the curious reader should incline to be more fully satisfied respecting this point, he may consult Bochart's *Chanaan*, D'Herbelot's *Bibliothèque Orientale*, and Walton's *Prolegomena*.

It thus appears, that the Pahlavi is a remnant of the old Persian, and that the latter is a cognate branch of the Hebrew, Chaldaic, Syriac, and Phœnician. We have likewise produced some presumptive proofs that the Zend was copied from the sacred language of the Egyptians; and shall now endeavour to explain by what changes and revolutions the language first mentioned arrived at its present summit of beauty and perfection.

gress of Persian guage.

We have already observed, that the Scythians, whom the old Persians called Σακαι, *Sacæ*, and whom the modern Persians call *Turan*, often invaded and overran Persia at a very early period. The consequence was, an infusion of Scythian or Tartarian terms, with which that language was early impregnated. This in all probability occasioned the first deviation from the original standard. The conquest of Alexander, and the dominion of his successors, must, one would imagine, have introduced an inundation of Greek words. That event, however, seems to have affected the language in no considerable degree, at least very few Grecian terms occur in the modern Persian.

The empire of the *Arsacidæ* or Parthians, we apprehend, produced a very important alteration in the ancient Persian. They were a demi-Scythian tribe; and as they conquered the Persians, retained the dominion of Persia during several centuries, and actually incorporated with the natives, their language must necessarily have given a deep tincture to the original dialect of the Persians. Sir William Jones has observed, that the letters of the inscriptions at *Istakhar* or Persepolis bear some resemblance to the old Runic letters of the Scandinavians. Those inscriptions we conceive to have been Parthian; and, as the Parthians were a Tartarian clan, we think this conjecture may be admitted till another more plausible is discovered. The Persians, it is true, did once more recover the empire, and under them began the reign of the Deree and Parsee tongues; the former consisting of the old Persian and Parthian highly polished; the latter of the same languages in their uncultivated vernacular dress. In this situation the Persian language remained till the invasion of the Saracens in 636, when these barbarians overran and settled in that fine country; demolished every monument of antiquity, records, temples, palaces, and every remain of ancient superstition; massacred or expelled the ministers of the Magian idolatry; and introduced a language, which though not entirely new, yet differed widely from the old exemplar.

But before we proceed to give some brief account of the modern Persian, we must take the liberty of hazarding one conjecture, which perhaps the adepts in the modern Persian may not be very well disposed to admit. In the modern language we find the ancient Persian names wonderfully distorted and deflected from that form under which they appear in Scripture, as well as in Ctesias, Megasthenes, and the Greek authors. From this it has been inferred, that not only the Greeks, but even the sacred historians of the Jews, have changed and metamorphosed them most unmercifully, in order to accommodate them to the standard of their own language. As to the Greeks, we know that this was their constant practice, but we cannot believe as much of the Hebrews, who, we make no doubt, wrote and pronounced the names of the Persian monarchs and governors of that nation nearly in the same manner with the native Persians. It is manifest, beyond all possibility of contradiction, that they altered neither the Tyrian and Phœnician names of persons and places when they had occasion to mention them, nor those of the Egyptians when any such occurred in their writings. The Babylonian and Chaldean names which are mentioned in the Old Testament vary in nothing from the Chaldean original. But no reason can be assigned why they should have transformed the Persian names more than the others. On the contrary, in Ezra, Nehemiah, and Esther, we find the Persian names faithfully preserved throughout.

Nothing now exists in Persic, except the Zend, that is older than the Saracen conquest.

The fact, we imagine, is this. Our modern admirers of the Persian have borrowed their names of the ancient kings and heroes of that country from romances and fabulous legends of more modern date and composition. The archives of Persia were destroyed by the Saracens; and nothing of importance was written in that country till two centuries after the era of Mohammed. What succeeded was all pure fiction and romance. The authors of those entertaining compositions either forged names of heroes to answer their purpose, or laid hold of such as were celebrated in the ballads of their country, or preserved by vulgar tradition. The names were no doubt very different from those of the ancient kings and heroes of Persia; and probably many of them had undergone considerable changes during the continuance of the Parthian empire. Upon this foundation has the learned Mr. Richardson erected a very irregular fabric, which, to use his own expression, seems to be built upon pillars of ice. He has taken much pains to invalidate the credit of the Grecian histories of the Persian empire, by drawing up in battle array against their records legions of romantic writers, who were not born till near a thousand years after the events had taken place; and, to complete the improbability, who lived two hundred years after all the chronicles of the Medes and Persians had been finally destroyed by the fury of the Saracens.

---

[1] *Cyropædia*, lib. i.

[2] Lib. ix. cap. 85.

After the decisive victory obtained over the Persians at Kadessa, their ancient government was overturned, their religion proscribed, their laws trampled under foot, and their civil transactions disturbed by the forcible introduction of the lunar for the solar kalendar; whilst, at the same time, their language became almost overwhelmed by an inundation of Arabic words, which, from that period, religion, authority, and fashion, incorporated with their idiom.

The most flourishing period of Persian literature.

From the seventh till the tenth century the Persian tongue, now impregnated with Arabic words, appears to have laboured under much discouragement and neglect. Bagdad, built by Almansor, became, soon after the year 762, the chief residence of the caliphs, and the general resort of the learned and ambitious from every quarter of the empire. At length the accession of the Buyah princes to the Persian throne marked in the tenth century the memorable epoch of the revival of Persian learning. About the year 977 the throne of Persia was filled by the great Azaduddawla, who first assumed the title of Sultan, afterwards generally adopted by eastern princes. He was born in Ispahan, and had a strong attachment to his native kingdom. His court, whether at Bagdad or in the capital of Persia, was the standard of taste and the favourite residence of genius. The native dialect of the prince was particularly distinguished, and soon became the general language of composition in almost every branch of polite learning. From the end of the tenth till the beginning of the fifteenth century may be considered as the most flourishing period of Persian literature. The epic poet Firdousi, in his romantic history of the Persian kings and heroes, displays an imagination and smoothness of numbers hardly inferior to Homer. The whole fanciful range of Persian enchantment he has interwoven in his poems, which abound with the noblest efforts of genius. This bard has stamped a dignity on the monsters and fictions of the East, equal to that which the prince of epic poetry has given to the mythology of ancient Greece. His language may at the same time be considered as the most refined dialect of the ancient Persian, the Arabic being introduced with a very sparing hand; whilst Sadi, Jami, Hafiz, and other succeeding writers, in prose as well as verse, have blended in their works the Arabic without reserve, gaining perhaps in the nervous luxuriance of the one language what may seem to have been lost in the softer delicacy of the other. Hence Ebn Fekreddin Anju, in the preface to the dictionary called *Farhang Jehanguiri*, says, that the Deree and the Arabic idioms were the languages of heaven; God communicating to the angels his milder mandates in the delicate accents of the first, whilst his stern commands were delivered in the rapid accents of the last.

For nearly three hundred years the literary fire of the Persians seems indeed to have been almost extinguished, since, during that time, hardly any thing of that people which deserves attention has appeared in Europe. Enough, however, has already been produced, to inspire us with a very high opinion of the genius of the East. In taste, the orientals are undoubtedly inferior to the best writers of modern Europe; but in invention and sublimity, they are excelled, perhaps equalled, by none. The Persians affect a rhetorical luxuriance, which to a European wears the air of unnecessary redundance. If to these leading distinctions we add a peculiar tone of imagery, of metaphor, and of allusion, derived from the difference of government, manners, temperament, and such natural objects as characterise Asia from Europe, we shall see, at one view, the great points of variation between the writers of the east and the west. Amongst the oriental historians, philosophers, rhetoricians, and poets, many will be found who would do honour to any age or people; whilst their romances, their tales, and their fables, stand upon a ground which Europeans have not yet been able to reach.

The genius of the modern Persic

We shall now annex a few observations on the genius of that noble language; though it is our opinion that the province of the philologist is to investigate the origin, progress, and final improvement of a language, without descending to its grammatical minutiæ or peculiar idiomatic distinctions. We have already observed, that the language under consideration is partly Arabic and partly Persian, though the latter generally has the ascendant. The former is nervous, impetuous, and masculine; the latter is flowing, soft, and luxuriant. Wherever the Arabic letters do not readily incorporate with the Persian, they are either changed into others or thrown away. Their letters are the Arabic with little variation, these being found more commodious and expeditious than the old letters of the Deree and Parsee. Their alphabet consists of thirty-two letters, which, like the Arabic, are read from right to left (their form and order will be learned from any grammar of that language). The letters are divided as usual into vowels and consonants. The Arabic characters, like those of the Europeans, are written in a variety of different hands; but the Persians write their poetical works in the Talick, which answers to the most elegant of our Italic hands.

Resemblance between Persian and English.

There is a great resemblance between the Persian and English languages in the facility and simplicity of their form and construction; the former, as well as the latter, has no difference of terminations to mark the gender either in substantives or adjectives; all inanimate things are neuter; and animals of different sexes have either different names, or are distinguished by the words *ner*, male, and *made*, female. Sometimes indeed a word is made feminine, after the manner of the Arabians, by having an affix annexed to it.

The Persian substantives have but one variation of case, which is formed by adding a syllable to the nominative in both numbers, and answers often to the dative, but generally to the accusative case in other languages. The other cases are expressed for the most part by particles placed before the nominative. The Persians have two numbers, singular and plural, the latter being formed by adding a syllable to the former. The Persian adjectives admit of no variation except in the degrees of comparison. The comparative is formed by adding *ter*, and the superlative by adding *terin* to the positive. The Persians have active and neuter verbs like other nations; but many of their verbs have both an active and neuter sense, which can be determined only by the construction. Those verbs have properly but one conjugation, and but three changes of tense, the imperative, the aorist, and the preterite; all the other tenses being formed by the help of particles or of auxiliary verbs. The passive voice is formed by adding the tenses of the substantive verb to the participle of the active.

In the ancient language of Persia there were few or no irregularities. The imperative, which is often irregular in the modern Persian, was anciently formed from the infinitive, by rejecting the termination *eeden*. Originally all

Persian anguage.

infinitives ended in *den*, till the Arabs introduced their harsh consonants before that syllable, which obliged the Persians, who always affected a sweetness of pronunciation, to change the old termination of some verbs into *ten*, and by degrees the original infinitive grew quite obsolete; yet they still retain the ancient imperative, and the aorists which were formed from it. This little irregularity is the only anomalous part of the Persian language, which, nevertheless, far surpasses in simplicity all other languages ancient or modern.[1]

tility of e Ara- an and ersianlan- uages.

In conclusion, we shall only take the liberty to remind our readers of the vast utility of the Arabian and Persian languages. Numberless events are preserved in the writings of the orientals which were never heard of in Europe, and must have for ever lain concealed from the knowledge of its inhabitants, had not these two tongues been studied and understood by the natives of this quarter of the globe. Many of those events have been transmitted to posterity in poems and legendary tales like the Runic fragments of Scandinavia, the romances of Spain, or the heroic ballads of our own country. Such materials as these, we imagine, may have suggested to Firdausi, the celebrated heroic poet of Persia, many of the adventures of his *Shahnameh;* which, like Homer when stript of the machinery of supernatural beings, is supposed to contain a great deal of true history, and a most undoubted picture of the superstition and manners of the times. The knowledge of these two languages has laid open to Europe all the treasures of oriental learning, and has enriched the minds of Britons with Indian science as much as the produce of the regions has increased their wealth and enervated their constitution.

ersian oetry.

Before we conclude this section, we shall, in order to render our inquiry the more complete, subjoin a few remarks on the nature of Persian poetry. The modern Persians borrowed from the Arabs their poetical measures, which are exceedingly various and complicated, consisting of nineteen different kinds; but the most common of them are the iambic or trochaic measures, and a metre that chiefly consists of those compounded feet which the ancients called *'Επιτριτους*, being composed of iambics and spondees alternately. In lyric poetry their verses generally consist of twelve or sixteen syllables; they sometimes, but seldom, consist of fourteen. Some of their lyric verses contain thirteen syllables; but the most common Persian verse is composed of eleven; and in this measure are written all their great poems, whether upon heroic or moral subjects, as the works of Firdausi and Jami, the Bostar of Sadi, and the Mesnavi of Gelaleddin. This species of verse answers to our common heroic rhyme, which was brought to so high a degree of perfection by Pope. The study of the Persian poetry is so much the more necessary, as there are few books or even letters written in that language, which are not interspersed with fragments of poetry. As to their prosody, nothing can be more easy or simple; and hence when the student can read prose easily, he will with a little attention read poetry with equal facility.

SECT. V. SANSCRIT AND BENGALESE LANGUAGES.

he San- rit one the most cient nguages.

The Sanscrit, although one of the most ancient languages in the world, was little known even in Asia until about the middle of the preceding century. Since that period, by the indefatigable industry of the learned and ingenious Sir William Jones, and the other worthy members of that society of which he had the honour to be president, this noble and ancient language was at length brought to light; and from it vast treasures of oriental knowledge have been communicated both to Europe and Asia; knowledge which, without the exertions of the establishment in question, must have lain concealed from the researches of mankind to the end of the world. In this section we propose to give to our readers such an account of that language as the limits of the present article, and the helps we have been able to procure, shall permit.

Sanscrit and Bengalese Languages.

The Sanscrit language has for many centuries lain concealed in the hands of the Brahmins of Hindustan. It is by them deemed sacred, and is consequently confined solely to the offices of religion. Its name imports the perfect language, or, according to the eastern style, the language of perfection; and we believe no language ever spoken by man is more justly entitled to that high character.

Traces of Sanscrit in every district of Asia and elsewhere.

The grand source of Indian literature, and the parent of almost every dialect from the Persian gulf to the China seas, is the Sanscrit; a language of the most venerable and most remote antiquity, which, though latterly shut up in the libraries of the Brahmins, and appropriated solely to the records of their religion, appears to have been current over most of the oriental world. Accordingly, traces of its original extent may be discovered in almost every district of Asia. Those who are acquainted with that language have often found the similitude of Sanscrit words to those of Persian and Arabic, and even of Latin and Greek; and that not in technical and metaphorical terms, which refined arts and improved manners might have occasionally introduced, but in the main ground-work of language, in monosyllables, the names of numbers, and appellations of such things as would be first discriminated on the immediate dawn of civilization.

The ancient coins of many different and distant kingdoms of Asia are stamped with Sanscrit characters, and mostly contain allusions to the old Sanscrit mythology. Besides, in the names of persons and places, of titles and dignities, which are open to general notice, even to the farthest limits of Asia, may be found manifest traces of the Sanscrit. The scanty remains of Coptic antiquities afford but little scope for comparison between that idiom and this primitive tongue; yet there still exists sufficient ground to conjecture, that, at a very early period, a correspondence did subsist between these two nations. The Hindus pretend, that the Egyptians frequented their country as disciples, not as instructors; that they came to seek that liberal education and those sciences in Hindustan, which none of their own countrymen had sufficient knowledge to impart. The validity of this claim we may perhaps examine hereafter.

Number of books in that language.

But although numberless changes and revolutions have from time to time convulsed Hindustan, that part of it which lies between the Indus and the Ganges still preserves this language whole and inviolate. Here they still offer a thousand books to the perusal of the curious; many of which have been religiously handed down from the earliest periods of human society.

Its characteristics.

The fundamental part of the Sanscrit language is divided into three classes: *Dhaat*, or roots of verbs, which some call primitive elements; *Shubd*, or original nouns; and *Evya*, or particles. The latter are indeclinable, as in all other languages; but the words comprehended in the two former classes must be prepared by certain additions and inflexions to fit them for a place in composition. And here it is that the art of the grammarian has found room to expand itself, and to employ all the powers of refinement. Not a syllable, not a letter, can be added or altered but by regimen; not the most trifling variation of the sense, in the minutest subdivision of declension or conjugation, can be effected without the application of several rules; all the different forms for every change of gender, number, case, person, tense, mood, or degree, are methodically arranged for the assistance of the memory, according to an unerring scale. The number of the radical or elementary parts is about seven hundred; and to these, as to the verbs of other languages, a very plentiful stock of verbal nouns owes its origin; but the latter are not thought to exceed those of the Greek either in quantity or variety.

---

[1] With respect to the more minute and intricate parts of this language, as well as its derivations, compositions, and constructions, we must refer our readers to Mininskie's *Institutiones Linguæ Turcicæ, cum rudimentis parallelis Linguarum Arab. et Pers.*; Sir William Jones's Persian Grammar; Mr. Richardson's Arabian and Persian Dictionary; D'Herbelot's *Bibliothèque Orientale;* and Dr. Hyde *de Religione veterum Persarum.* Our readers, who would penetrate into the innermost recesses of the Persian history, colonies, antiquities, connections, dialects, may consult the last mentioned author, especially chap. xxxv, entitled, *De Persia et Persarum nominibus, et de moderna atque veteri lingua Persica, ejusque dialectis.* In the preceding inquiry we have followed other authors, whose accounts appeared to us more natural, and much less embarrassing.

To the triple source of words above mentioned, every term of truly Indian origin may be traced by a laborious and critical analysis. All such terms as are thoroughly proved to bear no relation to any one of the Sanscrit roots, are considered as the production of some remote and foreign idiom, subsequently ingrafted upon the main stock; and it is conjectured, that a judicious investigation of this principle would throw a new light upon the first invention of many arts and sciences, and open a fresh mine of philological discoveries. We shall now proceed to give as exact an account of the constituent parts of this language as the nature of our design will permit.

Sanscrit copious & nervous.

The Sanscrit language is very copious and nervous. The first of these qualities arises in a great measure from the vast number of compound words with which it is almost overstocked. "The Sanscrit," says Sir William Jones, "like the Greek, Persian, and German, delights in compounds; but to a much higher degree, and indeed to such excess, that I could produce words of more than twenty syllables; not formed ludicrously like that by which the buffoon in Aristophanes describes a feast, but with perfect seriousness, on the most solemn occasions, and in the most elegant works." But the style of its best authors is wonderfully concise. In the regularity of its etymology it far exceeds the Greek and Arabic; and, like them, it has a prodigious number of derivatives from each primary root. The grammatical rules are also numerous and difficult, though there are not many anomalies. As one instance of the truth of this assertion, it may be observed, that there are seven declensions of nouns, all used in the singular, the dual, and the plural numbers, and all of them differently formed, according as they terminate with a consonant, with a long or a short vowel; and again, different also as they are of different genders. Not a nominative case can be formed to any one of these nouns without the application of at least four rules, which vary likewise with each particular difference of the nouns, as above stated; and to this it may be added, that every word in the language may be used through all the seven declensions, which is a full proof of the difficulty of the idiom.

The Sanscrit grammars are called *Beeākĕrun*, and of these there are many composed by different authors; some too abstruse even for the comprehension of the Brahmins, and others too prolix to be ever used as references. One of the shortest, named the *Sārăsootee*, contains between two and three hundred pages, and was compiled by Anoŏbhōōtēē Seroopĕnām Achārige, with a conciseness that can scarcely be paralleled in any other language.

Sanscrit alphabet.

The Sanscrit alphabet contains fifty letters; and it is one boast of the Brahmins, that it exceeds all other alphabets in this respect. But it must be observed, that as of their thirty-four consonants, nearly half carry combined sounds, and that six of their vowels are merely the correspondent long ones to as many which are short, the advantage seems to be little more than fanciful. Besides these, they have a number of characters which Mr. Halhed calls connected vowels, but which have not been explained by the learned president of the Asiatic Society.

The Sanscrit character used in Upper Hindustan is said to be the same original letter which was first delivered to the people by Brahma, and is now called *Diewnāgur*, or the language of angels, which shows the high opinion that the Brahmins have entertained of that character. Their consonants and vowels are wonderfully, perhaps whimsically, modified and diversified; but to enumerate them, in this place, would contribute very little either to the entertainment or instruction of our readers. All these distinctions are marked in the *Beids*,[1] and must be modulated accordingly, so that they produce all the effect of a laboured recitative; but by an attention to the music of the chant, the sense of the passage recited equally escapes the reader and the audience. It is remarkable, that the Jews in their synagogues chant the Pentateuch in the same kind of melody; and it is supposed that this usage has descended to them from the remotest ages.

Poetry.

The Sanscrit poetry comprehends a very great variety of different metres, of which the most common are these, viz. 1. The *munnee hurreneh chhund*, or line of twelve or nineteen syllables, which is scanned by three syllables in a foot; and the most approved foot is the anapæst. 2. The *cābee chhund*, or line of eleven syllables. 3. The *anŭshtofe chhund*, or line of eight syllables. Sanscrit poems are generally composed in stanzas of four lines, called *ashlogues*, which are regular or irregular. The most common ashlogue is that of the *anŭshtofe chhund*, or regular stanza of eight syllables in the line. In this measure the greatest part of the *Māhābārat* is composed. The rhyme in this kind of stanza should be alternate; but the poets do not seem to be very nice in the observance of a strict correspondence in the sounds of the terminating syllables, provided the feet of the verse are accurately disposed. This short *anŭshtofe ashlogue* is generally written by two verses in one line, with a pause between; so that the whole assumes the form of a long distich. The irregular stanza is constantly called *anyāchhund*, of whatever kind of irregularity it may happen to consist. It is most commonly compounded of the long line *cābee chhund* and the short *anŭshtofe chhund* alternately; in which form it bears some resemblance to the most common lyric measure of the English poetry.

Origin of this language.

Perhaps our readers may feel some curiosity to be informed as to the origin of this oriental tongue. If we believe the Brahmins themselves, it was coeval with the race of man, as we have already observed towards the beginning of this section. The Brahmins, however, are not the only people who ascribe a kind of eternity to their own particular dialect. We find that the Sanscrit in its primitive destination was appropriated to the offices of religion. It is indeed pretended, that all the other dialects spoken in Hindustan were emanations from that fountain, to which they might be traced back by a skilful etymologist. But this, we think, is an argument of no great consequence, since we believe that all the languages of Europe may, by the same process, be deduced from any one of those current in that quarter of the globe. By a parity of reason, all the different dialects of Hindustan may be referred to the language in question. Indeed, if we admit the authority of the Mosaic history, all languages whatsoever are derived from that of the first man. It is allowed that the language under consideration is impregnated with Persian, Chaldaic, Phœnician, Greek, and even Latin idioms. This, we think, affords a presumption that the Sanscrit was one of those original dialects which were gradually produced amongst the descendants of Noah, in proportion as they gradually receded from the centre of population. What branch or branches of that family emigrated to Hindustan, it is not easy to determine. That they were a party of the descendants of Shem is most nscrit Benga- e Lan- ages

---

[1] The books which contain the religion of the Brahmins.

probable, because the other septs of his posterity settled in that neighbourhood. The result then is, that the Hindus were a colony consisting of the descendants of the patriarch Shem.

It appears, however, by almost numberless monuments of antiquity still extant, that at a very early period a different race of men had obtained settlements in that country. It is now generally admitted, that colonies of Egyptians had peopled a considerable part of Hindustan. Numberless traces of their religion occur everywhere in those regions. The learned president himself is indeed positive, that vestiges of these sacerdotal wanderers may be found in India, China, Japan, Tibet, and many parts of Tartary. Those colonists, it is well known, were zealous in propagating their religious ceremonies wherever they resided, and wherever they travelled. There is at the same time even at this day a striking resemblance between the sacred rites of the vulgar Hindus and those of the ancient Egyptians. The prodigious statues of Salsette and Elephanta fabricated in the Egyptian style; the vast excavations hewn out of the rock in the former; the woolly hair of the statues, their distorted attitudes, their grotesque appearances, their triple heads, and various other configurations; all plainly indicate a foreign origin. These phenomena suit no other people upon earth so exactly as the sons of Mizraim. The Egyptian priests used a sacred character, which none knew but themselves; none were allowed to learn except their children and the *élite* of the initiated. All these features mark an exact parallel with the Brahmins of the Hindus. Add to this, that the dress, diet, lustrations, and other rites of both sects, bore an exact resemblance to each other. Sir William Jones has justly observed, that the letters of the Sanscrit, stripped of all adventitious appendages, are really the square Chaldaic characters. We learn from Cassiodorus the following particulars: "The height of the obelisks is equal to that of the circus; now the higher is dedicated to the sun, and the lower to the moon, where the sacred rites of the ancients are intimated by Chaldaic signatures by way of letters."[1] Here then it is plain that the sacred letters of the Egyptians were Chaldaic, and it is allowed that those of the Brahmins were of the same complexion; which affords another presumption in favour of the identity of the Sanscrit with those just mentioned.

That the Egyptians had at a very early period penetrated into Hindustan, is universally admitted. Osiris, their celebrated monarch and deity, according to their mythology, conducted an army into that country, and taught the natives agriculture, laws, religion, and the culture of the vine. He is said to have at the same time left colonies of priests, as a kind of missionaries, to instruct the people in the ceremonies of religion. Sesostris, another Egyptian potentate, likewise overran Hindustan with an army, and taught the natives many useful arts and sciences. When the Shepherd Kings invaded and conquered Egypt, it is probable that numbers of the priests, in order to avoid the fury of the merciless invaders, who demolished the temples and persecuted the ministers of religion, left their native country, and transported themselves into India. These, we should think, were the authors both of the language and religion of the Brahmins. This dialect, as imported by the Egyptians, was probably of the same contexture with the sacred language of that people, as it appeared many ages afterwards. The Indians, who have always been an inventive and industrious race of men, in process of time cultivated, improved, diversified, and constructed that language with such care and assiduity, that it gradually arrived at the high degree of perfection in which it at present appears.

Sanscrit and Bengalese Languages.

Had the learned president of the Asiatic Society, when he instituted a comparison between the deities of Hindustan on the one side, and those of Greece and Italy on the other, examined the analogy between the gods of Hindustan and those of Egypt, we think he would have performed a piece of service still more eminent.[2] Having first demonstrated the similarity between the divinities of India and Egypt, he might then have proceeded to investigate the resemblance of the Egyptian and Phœnician with those of Greece and Rome. By this process a chain would have been formed which would have enabled his readers to comprehend at one view the identity of the Zabian worship wherever it had been established, in the different regions of the earth.

It will be objected to this hypothesis that all the dialects of Hindustan being clearly reducible to the Sanscrit, it is altogether impossible that it could ever have been a foreign language. But to this we answer, that at the early period when this event is supposed to have taken place, the language of the posterity of the sons of Noah had not deviated considerably from the primitive standard, and consequently the language of the Egyptians and the Hindus was nearly the same. The Sanscrit was gradually improved. The language of the vulgar, as is always the case, became more and more different from the original archetype; but it still retained such a near resemblance to the mother-tongue as proved its kindred extraction.

Bengalese language.

To the preceding account of the Sanscrit language we shall annex a few strictures on the language of Bengal; which we believe is derived from the other, and is in most common use in the southern parts of Hindustan.

Though most of the ancient oriental tongues are read from right to left, like the Hebrew, Chaldaic, and Arabic, yet such as properly belong to the whole continent of India proceed from left to right like those of Europe. The Arabic, Persian, and others, are the grand sources whence the former method has been derived; but with these, the numerous original dialects of Hindustan have not the smallest connection or resemblance. The great number of letters, the complex mode of combination, and the difficulty of pronunciation, are considerable impediments to the study of the Bengal language; and the carelessness and ignorance of the people, no less than the inaccuracy of their characters, aggravate these inconveniences. Many of their characters are spurious; and these, by long use and the hurry of business, are now almost naturalized in the language.

The Bengal alphabet, like that of the Sanscrit, from which it is derived, consists of fifty letters, the form, order, and sound of which, may be learned from Mr. Halhed's grammar of the Bengal language. The vowels are divided into long and short, the latter of which are often omitted in writing. Most of the oriental languages are constructed upon the same principle, with respect to the omission of the short vowel. The Hebrews had no sign to express it before the invention of the Masoretic points; in Arabic it is rarely inserted unless upon very solemn occasions, as in the Koran; and in the modern Persian it is universally omitted. To all the consonants in the Sanscrit, however, the short vowel is an invariable appendage, and is never signified by any diacritical mark; but where the construction requires that the vowel should be dropped, a particular stroke is set under the letter. It is in vain to pretend, in a sketch like this, to detail the sound and pronunciation of these letters; this must be acquired by the ear and by practice.

In the Bengal language, there are three genders, as in Greek, Arabic, &c. The authors of this threefold division of genders, with respect to their precedence, appear to have considered the neuter as a kind of residuum resulting from the two others, and as less worthy or less comprehensive than either (see the section on the Greek.) The terminations usually applied upon this occasion are *aa* for the masculine, and *ee* for the feminine. In Sanscrit, as in Greek and Latin, the names of all things inanimate have different genders, founded on vague and incomprehensible distinctions: and this is also the case with the Bengal.

[2] See that gentleman's discourse, *Asiatic Researches*, vol. i.

Sanscrit and Bengalese nouns.

A Sanscrit noun, on its first formation from the general root, exists equally independent of case as of gender. It is neither nominative, nor genitive, nor accusative; nor is it impressed with any of those modifications which mark the relation and connection between the several members of a sentence. In this state it is called an *imperfect* or *crude* noun. To make a nominative of a word, the termination must be changed and a new form supplied. Thus we see, that, in the Sanscrit at least, the nominative has an equal right with any other inflection to be called a case. Every Sanscrit noun has seven cases, exclusive of the vocative, and therefore comprehends two more than even those of the Latin. Mr. Halhed details all the varieties of these with great accuracy, and to his grammar therefore we must refer our readers. The Bengal has only four cases besides the vocative; and in this respect it is much inferior to the other.

It would be difficult to account for the variety of words which have been allotted to the class of pronouns by European grammarians. The first and second person are chiefly worthy of observation; these two would seem to be confined to rational and conversable beings only. The third supplies the place of every object in nature; where it must necessarily be endued with a capacity of shifting its gender respectively as it shifts the subject; and hence it is in Sanscrit frequently denominated an adjective. One of the demonstratives *hic* or *ille* usually serves for this purpose; and generally the latter, which in Arabic has no other name than *dhemeer el ghaayb*, "the pronoun of the absentee," for whose name it is a substitute.

Bengalese pronouns.

In most languages where the verb has a separate inflection to each person, that inflection is sufficient to ascertain the personality; but in Bengal compositions, though the first and second persons occur very frequently, nothing is more rare than the usage of the pronoun of the third; and names of persons are inserted with a constant and disgusting repetition, to avoid, as it should seem, the application of the words HE and SHE. The second person is always ranked before the first, and the third before the second. The personal pronouns have seven cases, which are varied in a very irregular manner. Leaving these to the Bengalian grammar, we shall proceed to the *verb*.

The Sanscrit, the Arabic, the Greek, and the Latin verbs, are furnished with a set of inflections and terminations so comprehensive and complete, that by their form alone they can express all the different distinctions both of persons and time. Three separate qualities in them are perfectly blended and united. Thus by their root they denote a particular act, and by their inflection both point out the time when it takes place and the number of the agents. In Persian, as in English, the verb admits only of two forms, one for the present tense and one for the aorist; and it is observable, that whilst the past tense is provided for by a peculiar inflection, the future is generally supplied by an additional word conveying only the idea of time, without any other influence on the act implied by the principal verb. It is also frequently necessary that the different state of the action, as perfect or imperfect, be further ascertained in each of the tenses, past, present, and future. This also, in the learned languages, is performed by variations of inflections, for which other verbs and other particles are applied in the modern tongues of Europe and Persia.

Middle voice of Sanscrit verbs.

Every Sanscrit verb has a form equivalent to the middle voice of the Greek, used throughout all the tenses with a reflective sense, and the former is even the most extensive of the two in its use and office. For, in Greek, the reflective can only be adopted intransitively when the action of the verb descends to no extraneous subject; but in Sanscrit, the verb is both reciprocal and transitive at the same time. Neither the Sanscrit, nor the Bengalese, nor the Hindustanee, have any word precisely answering to the sense of the verb *I have*, and consequently the idea is always expressed by *est mihi*; and of course there is no auxiliary form in the Bengal verb corresponding to *I have written*, but the sense is conveyed in another mode. The very substantive, in all languages, is defective and irregular, and therefore the Sanscrit calls it a *semi-verb*. It is curious to observe that the present tense of this verb, both in Greek and Latin, and also in the Persian, appears plainly to be derived from the Sanscrit. In the Bengalese, this verb has but two distinctions of time, the present and the past; the terminations of the several persons of which serve as a model for those of the same tense in all other verbs respectively.

Characteristics Bengale verbs.

Verbs of the Bengal language may be divided into three classes, which are distinguished by their penultimate letter. The simple and most common form has an open consonant immediately preceding the final letter of the infinitive. The second is composed of those words the final letter of which is preceded by another vowel or open consonant going before it. The third consists entirely of causals derived from verbs of the first and second conjugations. The reader will easily conceive the impossibility of prosecuting this subject to any greater length; we shall therefore conclude with a few remarks collected from the grammar so often mentioned, which, we apprehend, may prove more amusing, if not more instructing.

The Greek verbs in μι are formed exactly upon the same principle with the Sanscrit conjugations, even in the minutest particulars. Instances of this are produced in many verbs, which from a root form a new verb by adding the syllable *mi*, and doubling the first consonant. This mode furnishes another presumption of the Egyptian origin of the Sanscrit. Many Greeks travelled into Egypt; many Egyptian colonies settled in Greece; and by one or other of these channels the foregoing innovation might have been introduced into the Greek language. To form the past tense, the Sanscrit applies a syllabic augment, as is done in the Greek; but the future has for its characteristic a letter analogous to that of the same tense in the Greek, and it omits the reduplication of the first consonant. It may be added that the reduplication of the first consonant, is not constantly applied to the present tense of the Sanscrit any more than to that of the Greek verb.

The natural simplicity and elegance of many of the Asiatic languages are greatly debased and corrupted by the continual abuse of auxiliary verbs; and this inconvenience has evidently affected the Persian, the Hindu, and the Bengalese idioms. The infinitives of verbs in the Sanscrit and Bengalese are always used as substantive nouns. Every body knows that the same mode of arrangement very often occurs in the Greek. In the Sanscrit language, as in the Greek, there are forms of infinitives and of participles comprehensive of time; and there are also other branches of the verb which seem to resemble the gerunds and supines of the Latin.

All the terms which serve to qualify, to distinguish, or to augment, either substance or action, are classed by the Sanscrit grammarians under one head; and the word used to express it literally signifies increase or addition. According to their arrangement, a simple sentence consists of three members; and the agent, the action, the subject, which, in a grammatical sense, are reduced to two, the noun and the verb. They have a particular word to specify such words as amplify the noun which imports quality, and answers to our adjectives or epithets. Such as are applied to denote relation or connection, are intimated by another term which may be translated preposition.

Sanscri and Be lese adj tives.

The adjectives in Bengalese have no distinction of gender or number; but in Sanscrit these words preserve the distinction of gender, as in the Greek and Latin. Prepositions are substitutes for cases, which could not have been extended to the number necessary for expressing all the several relations and predicaments in which a noun may be found, without causing too much embarrassment in the form of a declension. They are too few in the Greek language, a circumstance which occasions much inconvenience. The Latin is less polished than the Greek, and consequently bears a much nearer resemblance to the Sanscrit, both in words, inflections, and terminations.

The learned are now convinced that the use of numerical figures was first derived from India. Indeed the antiquity of their application in that country far exceeds the powers of investigation. All the numerals in Sanscrit have different forms for the different genders, as in Arabic. There appears to be a strong probability that the European method of computation was derived from India, as it is much the same with the Sanscrit, although we think the Europeans learned it from the Arabians. The Bengalese merchants compute the largest sums by *fours;* a custom evidently derived from the original mode of computing by the fingers.

The Sanscrit language, amongst other advantages, has a great variety in the mode of arrangement; and the words are so knit and compacted together, that every sentence appears like one complete word. When two or more words come together *in regimine,* the last of them only has the termination of a case; the others are known by their position; and the whole sentence, so connected, forms but one compound word, which is called a *foot.*

SECT. VI. OF THE CHINESE LANGUAGE.

tiquity the Chi- se.

The Chinese, according to the most authentic accounts, are a people of great antiquity. Their situation was such, as, even in the earliest ages of the world, in a great measure secured them from hostile invasion. Their little commerce with the rest of mankind excluded them from the knowledge of those improvements which a mutual emulation had often generated amongst other nations, who were situated in such a manner, with relation to each other, as served to promote a mutual intercourse and correspondence. As China is a large and fertile country, producing all the necessaries, conveniencies, and even luxuries of life, its inhabitants were not under the necessity of looking abroad for the two former, nor exposed to the temptation of engaging in foreign commerce, in order to procure the latter. Perfectly satisfied with the articles which their own country produced, they applied themselves entirely to the practice of agriculture and other arts connected with that profession; and their frugality, which they retain even to this day, taught them the lesson of being contented with little; consequently though their population was almost incredible, the produce of their soil proved abundantly sufficient to yield them a subsistence. Their inventions were their own; and as they borrowed nothing from other people, they gradually began to despise the rest of mankind, and, like the ancient Egyptians, branded them with the epithet of *barbarians.*

This people had at a very early period made amazing proficiency in the mechanical arts. But their progress in the liberal sciences, according to the latest and indeed the most probable accounts, was by no means proportioned. In mathematics, geometry, and astronomy, their knowledge was contemptible; and in ethics, or moral philosophy, the complexion of their laws and customs proves their skill to have been truly superficial. At present they value themselves very highly upon their oratorial talents; and yet of all languages spoken by any civilized people, theirs is confessedly the least improved. To what this untoward defect is owing, the learned have not yet been able to determine.

heir lan- ge an ginal gue.

The language of the Chinese is totally different from the idioms of all other nations, and bears very strong marks of an original tongue. All its words are monosyllabic, and their compositions and derivations are altogether unknown. Their nouns and verbs admit of no flexions; in short, every thing relating to their idiom is peculiar, and incapable of being compared with any other dialect that is spoken by any civilized people. Most barbarous languages exhibit something which resembles an attempt towards those diacritical modifications of speech; whereas the Chinese, after a space of four thousand years, have not advanced one step beyond the very first elements of ideal communication. This circumstance, we think, is a plain demonstration that they did not emigrate from that region where the primitive race of mankind is thought to have fixed its residence. Some have imagined, we believe with good reason, that they are a Tartarian race, which, breaking off from the main body of that numerous and widely-extended people, directed their march towards the south-east, where, falling in with delightful and fertile plains which their posterity now inhabit, they found themselves accommodated so much to their liking, that they dropped all desire of changing their habitations. The country of China is, indeed, so environed with mountains, deserts, and seas, that it would have been difficult for men in the primitive state to have emigrated into any of the neighbouring regions. Thus secluded from the rest of makind, the Chinese were, in all probability, left to the strength of their own inventive powers to fabricate a language, as well as the other arts and improvements necessary for the support and convenience of life.

It is indeed obvious that their vocabulary, when they emigrated from Tartary, was neither ample nor properly accommodated to answer the purposes of the mutual conveyance of ideas. With this slender stock, however, they seem to have been satisfied; for it does not appear that any additions were afterwards made to that which had been originally imported. Instead of framing a new class of terms by compounding the primitive ones; instead of diversifying them by inflections, or multiplying them by derivatives, as is done in every other language; they chose rather to retain their primitive words, and, by a great variety of modifications introduced upon their orthography or pronunciation, to accommodate them to a corresponding variety of significations. Were it possible to scrutinize all the Tartarian dialects, and to reduce them to their primitive monosyllabic character, perhaps the original language of the Chinese might be investigated and ascertained. We know that attempts have been made to compare it with some of the other Asiatic languages, especially the Hebrew; but the task proved unsuccessful, and no primeval identity has been discovered. Before this comparison could be instituted with the most distant prospect of success, the language last mentioned must be stripped of all its adventitious qualities; and not only so, but it must be reduced to the monosyllabic form, and then contrasted with the Chinese monosyllables, an undertaking which we are persuaded would not be readily executed. After all, we are convinced that no resemblance of any importance would be discovered.

Process of its fabrication.

The Chinese language must then, in our opinion, have been a Tartarian dialect, as the people themselves were colonists from Tartary. We have observed above, that this people have not hitherto found out the art of composition of words; a circumstance which is the more surprising, when we consider that, in the characters which form their written language, they employ many compositions. For example, the character by which they represent *misfortune,* is composed of one hieroglyphic which represents a *house,* and another which denotes *fire;* because the greatest misfortune that can befal a man is to have his house burned. With respect to the language which they use in speech, though they very often employ many words to express one thing, yet they never run them together into one word, making certain changes upon them that they may incorporate them more conveniently, but always preserve them entire and unaltered.

Paucity of words.

The whole number of words in the Chinese language does not exceed twelve hundred; and the nouns are only three hundred and twenty-six. It must certainly appear surprising, that a people whose manners are so highly polished and refined, should be able to express so many things as must of necessity be required in such a course of life by so small a number of words, and these too monosyllables. The difficulties which attend this singular mode must be felt at almost every instant; circumstances which, according to the ordinary course of things, should have induced them to attempt both an augmentation of the number of their words, and an extension of those which they had by composition and derivation. We learn from Duhalde that the Chinese have two different dialects: the one vulgar, which is spoken by the common people, and varies according to the different provinces; the other, called the *Mandarin language*, which is current only amongst the learned.[1] The latter is properly that which was formerly spoken at court in the province of *Kiang-nan*, and gradually spread amongst the polite people in the other provinces. Accordingly, this language is spoken with more elegance in the provinces adjoining to *Kiang-nan* than in any other part of the kingdom. By slow degrees it was introduced into all parts of the empire, and consequently became the universal language.

It then appears that the modern language of China was originally the court dialect, and utterly unknown to the bulk of the people. From this circumstance we think it may fairly be concluded that the dialect in question was deemed the royal tongue, and had been fabricated on purpose to distinguish it from the vulgar dialects. We learn from Heliodorus, that the Ethiopians had a royal language which was the same with the sacred idiom of the Egyptians.[2] This Mandarin tongue was originally an artificial dialect fabricated with a view to enhance the majesty of the court, and to raise its very style and diction above that of the rest of mankind. The Chinese, a wonderfully inventive people, might actually contrive a language of that complexion, with an intention to render it obscure and enigmatical.[3] Such a plan would excite their admiration, and would at the same time greatly exceed their comprehension. In process of time, when the Chinese empire was extended, the Mandarins who had been brought up at court, and understood nothing of the provincial dialects, found it convenient to have the most eminent persons in every province taught the language employed by themselves, in order to qualify them for transacting the affairs of government in a language which both parties understood. By this means the royal dialect descended to the vulgar, and in process of time became universal. The Tartar dialect formerly in use vanished; only a few vestiges of it remained, which gradually incorporating with the royal language, occasioned the variation of provincial tongues above mentioned.

We are therefore clearly of opinion, that the modern language of the Chinese was deduced from the original Mandarin, or court dialect, and that this last was an artificial speech fabricated by the skill and ingenuity of that most remarkable people. The learned have long held it as the primary dialect, because, say they, it bears all the marks of an original and unimproved language. In our opinion, nothing appears more ingeniously artificial. It is universally allowed that, in its structure, arrangement, idioms, and phraseology, it resembles no other language. Is not every learned man now convinced that all the Asiatic languages yet known, discover unequivocal symptoms of their cognation and family resemblance? The Ethiopians, Chaldeans, Arabians, Persians, Egyptians, Hebrews, Phœnicians, the Brahmins, Bengalese, the Hindus bordering upon China, all speak only different dialects of one language, varying from the original in dialect only, some in a greater, some in a lesser degree. Why then should the Chinese alone stand altogether insulated and unallied?

The languages of the north all possess congenial features. The Tartar or Tatar dialects of every clan, of every canton, of every denomination, exhibit the most palpable proofs of a near affinity. The Gothic and Sclavonian dialects, which pervade a great part of Europe and some parts of Asia, are obviously brethren, and may easily be traced up to an Asiatic original. Even some of the American jargon dialects contain words which clearly indicate an Asiatic or European original. Our readers, we flatter ourselves, will agree with us, that had the language of the Chinese been the original language, a resemblance must have still existed between it and its descendants. If it had originated from any other language, it would have retained some characteristic features of its parent archetype. But as neither of these is to be found in the fabric of the language under consideration, the conclusion must be, that it is a language entirely different from all other tongues; that it is constructed upon different principles, descended from different parents, and framed by different artists.

The Chinese themselves have a common and immemorial tradition, that their language was framed by *Yao*, their first emperor, to whom they attribute the invention of every thing curious, useful, and ornamental. Traditional history, when it is ancient, uniform, and universal, is generally well founded; and, upon this occasion we think the tradition above mentioned may be fairly admitted as a collateral evidence.

A proof o its artificia structure.

The paucity of vocables contained in this singular language, we consider as another presumption of its artificial contexture. The Chinese *Onomathetæ* would find it an arduous task to devise a great number of new terms, and would therefore rest satisfied with the smallest number possible. In other languages we find the same economy was observed. Rather than fabricate new words, men chose sometimes to adapt old words to new, and, upon some occasions, even to contrary significations. To spare themselves the trouble of coining new terms, they contrived to join several old ones into one; whence arose a numerous race of compounds. Derivatives too were fabricated to answer the same purpose. By this process, instead of creating new vocables, old ones were compounded, diversified, deflected, ramified, metamorphosed, and tortured into a thousand different shapes.[4]

The Greek is deservedly esteemed a very rich and copious language; yet its radical words have been curiously traced by learned men, who, after the most laborious and exact scrutiny, have found that they do not amount to more than three hundred. The Sanscrit language is highly compounded; its radical terms, however, are very few in number. Upon the whole, we think we may conclude, that the more any language abounds in compounds and derivatives, the smaller will be the number of its radical terms. The Arabic admits of no composition, and consequently its words have been multiplied almost *in infinitum;* the Sanscrit, the Persian, and the Greek, abound with compounds, and we find their radicals are few in proportion.

Methods o enriching language.

There are, we think, three different methods which may be employed in order to enrich and extend the range of a language. 1st, By fabricating a multitude of words; the plan which has been pursued by the Arabs. 2d, By framing a multitude of compounds and derivatives; the artifice employed by the Greeks, and the authors of the Sanscrit. 3d, By varying the signification of words without enlarging their number; the method practised by the Chinese and their colonists. The Arabians, we conceive, have shown the most fertile and inventive genius, since they have enriched their language by actually creating a new and a most numerous race of words. The fabricators of the Sanscrit and the collectors of the Greek have exhibited art, but comparatively little fertility of genius. Leaving, therefore, the Arabians, as in justice we ought, masters of the field in the contest relating to the formation of language, we may dispose the Greek and Sanscrit on the one side, and the Chinese on the other; and having made this arrangement, we may attempt to discover on which side the larger proportion of genius and invention seems to rest.

e.

The Greek and Sanscrit (for we have selected them as being the most highly compounded) exhibit a great deal of art in modifying, arranging, and diversifying their compounds and derivatives, in such a manner as to qualify them for intimating complex ideas; but the Chinese have performed the same office by the help of a race of monosyllabic notes, simple, inflexible, invariable, and at the same time few in number. The question then comes to be, whether more art is displayed in new-modelling old words by means of declensions, compounds, and derivatives; or in devising a plan according to which monosyllabic radical terms, absolutely invariable, should, by a particular modification of sound, be made to answer all the purposes performed by the other. The latter appears to us much more ingeniously artificial. The former resembles a complicated machine composed of a vast number of parts, congenial indeed, but loosely connected; the latter may be compared to a simple, uniform engine, easily managed, and having all its parts properly adjusted. Let us now see in what manner the people in question managed their monosyllabic notes, so as to qualify them for answering all the purposes of speech.

Although the number of words in the Chinese language does not amount to above twelve hundred, yet that small number of vocables, by their artificial management, is sufficient to enable them to express themselves with ease and perspicuity upon every subject. Without multiplying words, the sense is varied almost *in infinitum* by the variety of the accents, inflections, tones, aspirations, and other changes of the voice and enunciation; circumstances which make those who do not thoroughly understand the language frequently mistake one word for another. This will appear obvious by an example. The word *teov* pronounced slowly, drawing out the *v* and raising the voice, signifies a *lord* or *master*. If it be pronounced with an even tone, lengthening the *v*, it signifies a *hog*. When it is pronounced quickly and lightly, it imports a *kitchen*. If it be pronounced in a strong and masculine tone, growing weaker towards the end, it signifies a *column*.

By the same economy, the syllable *po*, according to the various accents, and the different modes of pronounciation, has eleven different significations. It signifies *glass, to boil, to winnow rice, wise or liberal, to prepare, an old woman, to break or cleave, inclined, a very little, to water, a slave or captive*. From these examples, and from almost numberless others which might be adduced, it is abundantly evident that this language, which at first sight appears so poor and confined, in consequence of the small number of the monosyllables of which it is composed, is notwithstanding very copious, rich, and expressive. Again, the same word joined to various others, imports a great many different things; for example, *mou*, when alone, signifies a *tree, wood*, but when joined with another word, it has many other significations. *Mou leoo*, imports wood prepared for building; *mou lan* signifies bars, or wooden grates; *mou hia*, a box; *mou sang*, a chest of drawers; *mou tsiang*, a carpenter; *mou eul*, a mushroom; *mou nu*, a sort of small orange; *mou sing*, the planet Jupiter; *mou mien*, cotton. This word may be joined to several others, and has as many different significations as it has different combinations.

Thus the Chinese, by a different arrangement of their monosyllables, can compose a regular and elegant discourse, and communicate all their ideas with energy and precision; nay even with gracefulness and propriety. In these qualities they are not excelled either by the Europeans or Asiatics, who use alphabetical letters. In fine, the Chinese so naturally distinguish the tones of the same monosyllable, that they comprehend the sense of it, without exercising the least reflection on the various accents by which it is determined.

Effects of this method on pronunciation.

We must not, however, imagine, as some authors have related, that this people cant in speaking, and make a sort of music which is very disagreeable to the ear; the various tones are pronounced so curiously, that strangers find it difficult to perceive their difference even in the province of *Kiang-nan*, where the accent is more perfect than in any other. The nature of it may be conceived by the guttural pronunciation in the Spanish language, and by the different tones which are used in the French and Italian. These tones are almost imperceptible; yet they have different meanings, a circumstance which gave rise to the proverb, that *the tone is everything*.

If the fineness and delicacy of their tones are such as to be scarcely perceptible to a stranger, we must suppose that they do not rise high, but only by small intervals; so that the music of their language must somewhat resemble the music of the birds, which is within a small compass, but nevertheless of great variety of notes. Hence it follows, that strangers will find it very difficult, if not impossible, to learn this language; more especially if they have not a delicate ear and a flexible voice, and also much practice. The great difference then between the Chinese and Greek accents consists in this, that the Greeks had but two accents, the grave and acute, distinguished by a large interval, and that not very exactly marked; for the acute, although it never rises above a fifth higher than the grave, did not always rise so high, and was sometimes pitched lower according to the voice of the speaker. The Chinese must have many more accents, and the intervals between them must be much smaller, and much more carefully marked; for otherwise it would be impossible to distinguish them. At the same time, their language must be much more musical than the Greek, and perhaps more so than any language ought to be; though this has becomes necessary for the purposes above mentioned. Duhalde is positive that notwithstanding the perpetual variation of accents in the Chinese tongue, and the almost imperceptible intervals between these tones, their enunciation does not resemble singing. Many people, however, who have resided in China, are equally positive that the tone in which they utter their words does actually resemble *canting;* and this, when we consider the almost imperceptible intervals by which they are perpetually raising and lowering the pitch of their voice, appears to us highly probable.

As the people of whose language we are treating at present communicate a variety of different significations to their monosyllabic terms by means of varied accentuation, so they employ quantity for the very same purpose. By lengthening or shortening the vowels of their words, they employ them to signify very different things; and they perform the same thing by giving their words different aspirations, as likewise by sounding them with different degrees of roughness and smoothness, and even sometimes by the different motion, posture, or attitude, with which their enunciation is accompanied. By these methods of diversifying their monosyllables, says Duhalde, they make three hundred and thirty of them serve all the purposes of language, and these too not much varied in their termination; since all the words in that language either terminate with a vowel or with the consonant *n*, sometimes with the consonant *g* annexed.

From this account, we think it is evident that the Chinese, by a wonderful exertion of ingenuity, do, by different tones and prosodical modifications, by means of a very inconsiderable number of invariable radicals, actually perform all that the most polished nations have been able to achieve by their compounds, derivatives, &c. diversified by declensions, conjugations, and flexions of every kind; circumstances which, in our opinion, reflect the greatest honour on their inventive powers.

Grammar of the Chinese.

With respect to the grammar of this language, as it admits of no flexions, all their words being indeclinable, their cases and tenses are, therefore, formed by particles. They have no idea of genders; and even the distinction of numbers, which in almost all other languages, however unimproved, is marked by a particular word, is in the Chinese indicated only by a particle. They have no more than the three simple tenses, namely, the past, present, future; and for want of different terminations, the same word stands either for the verb or the verbal substantive, the adjective or the substantive derived from it, according to its position in the sentence. The Chinese language being composed of monosyllables, and these indeclinable, can scarcely be reduced to grammatical rules. We shall, however, attempt to lay before our readers as much of the texture of that singular dialect as may enable them to form some vague idea of its genius and constitution; beginning with the letters, and proceeding regularly to the remaining parts as they naturally succeed each other.

Chinese letters or characters.

The art of joining the Chinese monosyllables together is extremly difficult, and requires a very long and laborious course of study. As they have only figures by which they can express their thoughts, and have no accents in writing to vary the pronunciation, they are obliged to employ as many different figures or characters as there are different tones, which give an equal number of different significations to the same word. Besides some single characters signify two or three words, and sometimes even a whole period. For example, to write these words, *good morrow, Sir*, instead of joining the characters which signify *good* and *morrow* with that of *Sir*, a different character must be used, and this character alone expresses these three words; a circumstance which greatly contributes to multiply the Chinese characters.

This method of joining the monosyllables is indeed sufficient for writing so as to be understood; but it is deemed trifling, and is used only by the vulgar. The style which is employed, in order to shine in composition, is quite different from that which is used in conversation, though the words are in reality the same. In writings of that species, a man of letters must use more elegant phrases, and more lofty expressions, and the whole must be dignified with tropes and figures which are not in general use, but in a peculiar manner adapted to the nature of the subject in question. The characters of Cochin-china, of Tong-king, and of Japan, are the same with those of the Chinese, and signify the same things; though, in speaking, these nations do not express themselves in the same manner. The language of conversation is therefore very different, and they are not able to understand each other; whilst, at the same time, they understand each other's written language, and have all their books in common.

The learned must not only be acquainted with the characters which are employed in the common affairs of life, but must also understand their various combinations, and the numerous and multiform dispositions and arrangements which of several simple strokes make the compound characters. The number of their characters amounts to about eighty thousand; and the man who knows the greatest number of them is of course the most learned. From this circumstance we may conclude, that many years must be employed to acquire the knowledge of such a prodigious number of characters, to distinguish them when they are compounded, and to remember their shape and import. After all, a person who understands ten thousand characters may express himself with tolerable propriety in this language, and may be able to read and understand a great number of books. The generality of their learned men do not understand above fifteen or twenty thousand, and few of their doctors have attained to the knowledge of above forty thousand. This prodigious number of characters is collected in their great vocabulary called *Hai-pien*. They have radical letters, which show the origin of words, and enable them to find out those which are derived from them; for instance, the characters of mountains, trees, man, the earth, a horse, under which must be sought all that belongs to mountains, trees, man, &c. In this search one must learn to distinguish in every word those strokes or figures which are above, beneath, on the sides, or in the body of the radical figure.

Clemens Alexandrinus (see the section on the Chaldaic language) informs us, that the Egyptians employed three sorts of characters: The first was called the *epistolographic* which was used in writing letters; the second was denominated *hieratic*, and peculiar to the sacerdotal order; the last formed the *hieroglyphical*, which was appropriated to monumental inscriptions and other public memorials. This mode of representation was twofold. One, and the most simple, was performed by describing the picture of the object which they intended to represent, or at least one that resembled it pretty nearly; as when they exhibited the sun by a circle and the moon by a crescent. The other was properly symbolic; as when they marked *eternity* by a serpent with the emblem of life, and the *air* by a man clothed in an azure robe studded with stars.

The Chinese, in all probability, had the same variety of characters. In the beginning of their monarchy, they communicated their ideas by drawing on paper the images of the objects they intended to express; that is, they drew the figure of a bird, a mountain, a tree, waving lines, to indicate birds, mountains, forests, rivers, and so on. There were, however, to be communicated an infinite number of ideas, the objects of which do not fall under the cognizance of the senses; such as the soul, the thoughts, the passions, beauty, deformity, virtues, vices, the actions of men and other animals. This inconvenience obliged them to alter their original mode of writing, which was too confined to answer that purpose, to introduce characters of a more simple nature, and to invent others to express those things which are the objects of our senses.

Chinese truly hi glyphica

These modern characters are, however, truly hieroglyphical, since they are composed of simple letters which retain the signification of the primitive characters. The original character for the sun was a circle thus ⊙; and this they called *ga*. They now represent that luminary by the figure |☰|, to which they still give the original name. But human institutions having annexed to these last-framed characters the very same ideas indicated by the original signs, the consequence is, that every Chinese letter is actually significant, and that it still retains its significancy, though connected with others. Accordingly the word *tsai*, which imports misfortune, or calamity, is composed of the letter *mien*, a house, and the letter *ho*, fire; so that the symbolical character for misfortune is the figure of a house on fire. The Chinese characters, then, are not simple letters without any signification, like those of the Europeans and of other Asiatics; but when they are joined together, they are so many ideagraphic signs, which represent or express thoughts.

Upon the whole, the original characters of the Chinese were real pictures; the next improvement was the introduction of the symbolical character; whilst the third and last stage was the present mode, in which artificial signs have been fabricated, to represent such thoughts or ideas as could not be represented by one or other of the methods above described. Duhalde (vol. ii. p. 400, *et seq.*) has furnished us with rules for pronouncing the Chinese vowels and consonants; a piece of information which, as it would be of little consequence to our readers, we shall therefore pass over, and proceed to give a brief account of the Chinese grammar. As the whole language is composed of monosyllables, and these indeclinable, its grammatical structure must be simple and obvious; we shall, therefore, only mention what to us appears singular and important.

C ese pa of sp h.

In the Chinese language there is no diversity of genders or cases, and consequently no declensions. Very often the noun is not distinguished from the verb; and the same word which in one situation is a substantive, may in another become an adjective, and even a verb. The adjective always goes before the substantive; but if it follow it, it becomes a substantive. The cases and numbers are known only by the composition. The plural number is distinguished by the particle *men*, which is common to all nouns; but when the noun is preceded by some word which signifies number, the particle *men* is not annexed. The Chinese genitive, both singular and plural, when it comes after nouns, is often made by *ti*; and there is no other case in that language. The same particle is sometimes placed after pronouns, as if they were derivatives. The comparative degree is formed by adding the particle *keng*, which is always placed before the noun, and signifies *much*. The particle *to* is sometimes used, and likewise imports *much*. The Chinese have only three personal pronouns, *nqo*, I, *ni*, thou, and *ta*, he; and these become plural by adding the syllable *men*. They are made possessive by adding the syllable *ti*, as *nqo ti*, mine, *ni ti*, thine, *ta ti*, his. The patronymics are formed by putting the name of the city, country, or the like, after the pronoun; and *chon* is the relative pronoun *who*, *what*, *which*. Chinese verbs have only three tenses; the preterperfect, the present, and the future. When there is no particle added to the verb, it is the present; the preterperfect is made by adding the particle *leao*; and to distinguish the future tense they use the particle *tsiang* or *hoei*; these being all the varieties incident to their verbs. The Chinese language has no words which are properly adverbs; they only become so by custom, or by the place which they occupy in discourse. They are often obliged to employ several words to express the adverbs of other languages. They have none which are demonstrative, or proper for calling or exhorting; but in their stead they are obliged to use nouns and verbs.

Th nu- me.

Perhaps our readers may wish to know the Chinese numerals, and imagine that they bear a resemblance to those of the European or other Asiatic dialects. In this supposition, however, they will find themselves disappointed. The numerals are as follow:—*y*, one; *eut*, two; *san*, three; *sace*, four; *ou*, five; *lou*, six; *tsi*, seven; *po*, eight; *kieou*, nine; *che*, ten; *che y*, eleven; *eut che*, twelve; *san che*, thirteen; *pe*, one hundred; *eut pe*, two hundred; *y tsien*, one thousand; *y ouan*, one thousand; *che ouan*, twenty thousand; *eut ouan*, one hundred thousand; *che ouan*, two hundred thousand; *ypeouan* one million. There are a great many particles proper to numbers in the Chinese language, which are frequently used, and in a way peculiar to it; for every numeral has a particle importing the object to which it is attached. Thus *co* is used for man, and *y co* for a woman; *hoei* is used for illustrious men; *tche* or *tchi* is used for ships, dogs, hens; *mey* is used for pearls and precious things; *pen* is used for books; *teng* is appropriated to oxen and cows; *too* is used for letters and little bundles of paper; *oo* is employed for corn and pulse. Those distinctions indicate a language manufactured on purpose to be employed by people who were too high and too haughty to converse with the vulgar.

Style of the Chinese writers.

The style of the Chinese, in their elaborate compositions, is mysterious, concise, and allegorical, after the manner of the orientals. It is often obscure to those who do not understand the language thoroughly; and it requires a considerable degree of skill to avoid mistakes in reading an author of elegance and sublimity. Their writers express a great deal in few words; and their expressions are lively, full of spirit, intermingled with bold comparisons and lofty metaphors. They affect to insert in their compositions many sentences borrowed from their five canonical books; and as they compare their books to pictures, so they liken these quotations to the five principal colours employed in painting; and in this their eloquence chiefly consists. They prefer a beautiful character to the most finished picture; and nothing is more common than to see a single page covered with old characters (if they happen to be fair and elegant) sold at a very high price. They honour their characters in the most common books; and when they happen to light by chance upon a printed leaf, they gather it up with the greatest care and respect.

In China there are three varieties of language; that of the common people, that of the people of fashion, and that employed in writing books. Though the first is not so elegant as either of the other two, it is not however inferior to our European languages; notwithstanding those who are but superficially acquainted with the Chinese may imagine it uncouth and barbarous. This low and rude language is pronounced and written many different ways, as is generally the case in other countries. But a more polished, and at the same time a much more energetic, language, is employed in an almost infinite number of novels; some perhaps true, but many more the vehicles of fiction. These are replete with lively descriptions, characters highly finished, morality, variety, wit, and vivacity, in such a degree as to equal in purity and politeness the most celebrated authors of Europe. This was the language of the Mandarins; but though exquisitely beautiful in its kind, it was still inferior to the language of books. This last might be styled the hypersublime; and of it there are several degrees and intervals before an author can arrive at what is called the language of the *king*. This mode of writing cannot be well understood without looking upon the letters; but when understood, it appears easy and flowing. Each thought is generally expressed in four or six characters; nothing occurs that can offend the nicest ear; and the variety of the accents with which it is pronounced produces a soft and harmonious sound.

The difference between the *king* and their other books consists in the difference of the subjects upon which they are written. Those of the former are always grand and sublime, and of course the style is noble and elevated. Those of the latter approach nearer to the common affairs and events of life, and are of consequenee detailed in the Mandarin tongue. In writing on sublime subjects no punctuation is used. As these compositions are intended for the learned only, the author leaves to the reader to determine where the sense is complete; and those who are well skilled in the language readily find it out.

The copiousness of the Chinese language is in a great measure owing to the multitude of its characters. It is likewise occasioned, in some degree, by the difference of their signification, as also by the artificial method of conjunction, which is performed most commonly by uniting the characters two and two, frequently three and three, and sometimes four and four.

Their books numerous and bulky.

Their books are very numerous and bulky, and of course exceedingly cumbrous. A dictionary of their language was compiled in the eighteenth century. It consisted of ninety-five large volumes; and an appendix was annexed of twenty-five volumes. Their other books are voluminous in proportion. The Chinese, one may say, are a nation of learned men. Few people of rank neglect the belles lettres: for ignorance in a man of any degree of eminence is deemed an indelible stain on his character.[1]

Obstacles to improvement in science and literature.

The Chinese have ever looked upon themselves as greatly superior to the rest of mankind. In ancient times they entertained such contemptible notions of foreigners, that they scorned to have any further commerce with them than to receive their homage. They were indeed, at a very early period, highly revered by the Indians, Persians, and Tartars; and in consequence of this veneration, they looked upon themselves as the favourites of Heaven. They imagined that they were situated in the middle of the earth, in a kind of paradise, in order to give laws to the rest of mankind. Other men they looked upon with contempt and disdain, deeming them deformed in body and defective in mind, cast out into the remote corners of the world as the dross and refuse of nature. They boasted that they themselves alone had received from God rational souls and beautiful bodies, in order to qualify them for being sovereigns of the species.

Such are the sentiments of the Chinese; and with such sentiments it is by no means surprising that their improvements in language, in writing, and other appendages of the belles lettres, have not been proportioned to their progress in mechanics. When people are once fully persuaded that they have already arrived at the summit of perfection, it is natural for them to sit down contented, and to solace themselves with the idea of their own superior attainments. The Chinese had early entertained an exalted opinion of their own superiority to the rest of mankind; and therefore imagined that they had already carried their inventions to the *ne plus ultra* of perfection. The consequence was, that they could make no exertions to carry them higher.

The Chinese, for the space of three thousand years, had almost no intercourse with the rest of mankind. This was the consequence of their insulated situation. They of course compared themselves with themselves; and finding that they excelled all their barbarian neighbours, they readily entertained an opinion that they excelled all the rest of mankind in an equal proportion. This conceit at once stifled the emotions of ambition, and deprived them of all opportunities of learning what was going forward in other parts of the world. They despised every other nation. People are little disposed to imitate those whom they despise; and this perhaps may be one reason why they are at this day so averse to adopt the inventions of Europeans.

A superstitious attachment to the customs of the ancients is the general character of the Asiatic nations. This is evidently a kind of diacritical feature amongst the Chinese. The institutions of *Fohi* are looked up to amongst them with the same veneration as those of *Thoth* were amongst the Egyptians. Amongst the latter, there was a law which made it capital to introduce any innovation into the arts of music, painting, or statuary, as instituted by that legislator. We hear of no such law amongst the former; but custom established, and that invariably, for a space of three thousand years, might operate as forcibly amongst them as a positive law did amongst the people first mentioned. An attachment to ancient customs is often more powerful and more coercive than any law which can be promulgated and enforced by mere human authority. These circumstances, we think, may be assigned as the impediments to the progress of the Chinese in the belles lettres, and perhaps in the cultivation of the sciences.

Chinese words found in other languages.

Though the language of the Chinese is confessedly different from all other known languages in its character and construction, it nevertheless contains a great number of words evidently of the same origin with those which occur in other dialects, used by people, who, according to the natural course of things, could never have been connected with that remote country. As an appropriate conclusion to this section, we shall produce here a few of these coincidencies.

1. *China*, or, as the orientals write it, *Sin*, is perhaps the Latin *sinus*, the bosom, the heart, the middle. The Chinese actually imagine that their country is situated in the very middle of the earth, and consequently call it *Cham*, the middle, the heart, a denomination which exactly suits their opinion. 2. *Tu*, in Chinese, intimates every thing that falls under the cognizance of the senses, every thing that strikes the sight; in Latin, *tueor*. 3. *Ta*, a table, a a plank, a figure that renders every thing sensible; *secondly*, to see, to look upon, to appear; Greek ταν τανα, whence τεινω, *tendo*. 4. *Tue*, to examine attentively, to inspect carefully. 5. *Tui*, the most apparent, chief, principal, first; *secondly*, lightning, thunder. 6. *Teu*, a sign by which we know one, letter of acknowledgment. All these ideas are contained in the Hebrew תו, *thu*, *signum*, which we believe has produced the Egyptian *theuth*, the god or godlike man who invented letters, geometry, music, and astronomy. 7. *Tai*, a dye, a theatre; Greek of old, θεαω, then θεαομαι, to see, to look. 8. *Tam*, Latin *tantum*, so much. 9. *Tan*, land, country, region, a syllable annexed to the end of a great number of words, thus, *Aqui tan*, *Aquitania*, a land o. water; *Mauri tan*, *Mauritania*, the land of the Moors. The orientals prefix *s*, and hence *Farsi stan*, *Farsistan*, the land or country of the Persians; *Chusi stan*, *Chusistan*, the country of Chuz; *Turque stan*, *Turquestan*, the land of the Turks. 10. *Ti*, a chief, an emperor, a title of dignity; whence the Greek τιω, to honour, and also the word *di*, bright, glorious; Δις, Jupiter, Διος, divine, the Latin *Dius*, now *Deus*, God, and *Divus*, with the *digamma Æolicum* inserted, the Celtic *Dhia*, &c. It signified originally bright, glorious, and was an epithet of the sun. 11. *Tum*, Latin *tumeo*, to swell. 12. *Liven*, to love; Hebrew לב, *leb*, the heart; Latin *libet*. This word pervades all the dialects of the Gothic tongue, still retaining either the same or a nearly analogous signification. 13. *Li*, letters; Latin, *lino*, to daub, as the Chinese actually do in forming their letters. 14. *Lo*, to contain, that which contains; Celtic, *log;* French, *loge*, *logis*, *loger*. 15. *Lim*, a rule; hence the Latin, *linea*, a line. 16. *Su*, with; Greek, συν, with; Celtic, *cyn*, *cym;* Latin, *cum*, *con*, &c. 17. *Xim*, very high, elevated, sacred, perfect; Latin, *eximius*. 18. *Sin*, the heart; Persian, *Sin*, the heart. 19. *Sien*, chief, first; Celtic, *can*, *céan*, *san*, the head; metaphorically, the chief, the first, the principal; Thibet, *sen*, or *ken*, great, elevated; Arabic, *same*, to be elevated or raised. 20. *Sim*, or *Sing*, a constellation, a star, an element; Hebrew, *shem;* Greek, σημειον, σημα; Latin, *signum*. 21. *Sie*, a man of learning; Goth. Sax. Engl. see, to see, seer. 22. *Cem*, a priest; Hebrew, *cohen;* Syriac, *con;* Egyptian, *can*, *cun*. 23 *Quin*, a king; Celtic, *ken*, *kend*, head, chief; Gothic, *koanig;* Germ. Flem. Engl. *king*, also *queen*. 24. *Hu*, a door; Goth. Germ. Engl. *hus*, *hausen*, *house*. 25. *Min*, a river; Welch, *men*, the water of a river; Latin, *mano*, to flow, and perhaps *amoenus*, pleasant. 26. *Hen*, hatred; Greek, αἰνος, cruel, horrible, odious. 27. *Kiven*, a dog; Greek, κυων, the same. 28. *Ven*, beauty; Latin, *Venus*, *venustas;* Iceland. Swed. *wen*, pleasant; Scotch, *winsome*. 29. *Han*, the soul, breath; Greek, ἀνεμος; Latin, *anima*, *animus*.

To these instances of the analogy between the Chinese language and those of the other people of Asia and Europe many more might be added; but the preceding, it is hoped, will serve as a specimen, which is all that can be expected in an inquiry such as the present.[1]

---

[1] For their manner of writing, the implements with which they write, and the materials upon which they draw their characters, we must refer our readers to the article WRITING. It would, we believe, afford our readers considerable pleasure, could we discover and explain the reasons which have hitherto prevented the Chinese from adopting the letters employed from time immemorial by the other nations of Europe and Asia.

SECT. VII. OF THE GREEK LANGUAGE.

rigin of e Greeks

Before we enter upon the consideration of the essential and constituent parts of this noble language, we must beg leave to settle a few preliminaries, which, we trust, will serve to throw some light upon many points that will come under our consideration in the course of the following disquisition.

The Greeks, according to the most authentic accounts, were descended of Javan or Jon, the fourth son of Japhet, the eldest son of the patriarch Noah. The Scriptures of old, and all the orientals to this day, call the Greeks Jonim, or Jaunam, or Javenoth. We have already observed, in the beginning of the article concerning the Hebrew language, that only a few of the descendants of Ham, and the most profligate of the posterity of Shem and Japhet, were concerned in building the tower of Babel. We shall not now resume the arguments then collected in support of that position, but proceed to investigate the character of that branch of the posterity of Javan which inhabited Greece and the neighbouring regions.

At what period the colonists arrived in these parts cannot be certainly determined; nor is it of any great importance in the question before us. That they carried along with them into their new settlements the language of Noah and his family, is, we think, a point which cannot be controverted. We have endeavoured to prove that the Hebrew, or at least one or other of its sister-dialects, was the primeval language of mankind. The Hebrew, then, or one of its cognate branches, was the original dialect of the Jonim or Greeks.

But however this may be, before these people make their appearance in profane history, their language appears to have deviated very widely from this original archetype. By what means, at what period, and in what length of time this change was introduced, is, we believe, a matter not easy to be elucidated. That it was progressive, is abundantly certain from the rules both of analogy and of reason.

hey were g a bar- rous peo-

The colonies, which traversed a large tract of country before they arrived at their destined settlements, must have struggled with numberless difficulties in the course of their peregrinations. The earth, during the period which immediately succeeded the universal deluge, must have been covered with forests, and intersected with swamps, lakes, rivers, and numberless other impediments. As the necessaries, and a few of the conveniencies of life, will always engross the first cares of mankind, the procuring of these comforts will, of necessity, exclude all concern about arts and sciences which are unconnected with such primary pursuits. Hence we think it probable, that most of those colonies that migrated to a very great distance from the plains of Shinar, which are believed to have been the original seat of mankind, in a great measure neglected the practice of the polite but unnecessary modes of civilization, which their ancestors were acquainted with and practised before the era of their migration. Certain it is, that those nations which continued to reside in the neighbourhood of that centre of civilization, always appear in a cultivated state; whilst, at the same time, the colonists who removed to a considerable distance appear to have sunk into barbarism, at a period more early than the annals of profane history can reach. This appears to have been the situation of the primary inhabitants of Greece. Their own historians, the most partial to their own countrymen that can well be imagined, exhibit a very unpromising picture of their earliest progenitors. Diodorus Siculus, in delineating the character of the original men, sketches his outline, we believe, from the first inhabitants of Greece.[2] He represents them as absolute savages, going out in small parties to make war upon the wild beasts of the field, which, according to him, kept them in continual alarm. "Necessity obliged them to band together for their mutual security; they had not sagacity enough to distinguish between the wholesome and poisonous vegetables; nor had they skill enough to lay up and preserve the fruits of autumn for their subsistence during the winter." The scholiast on Pindar describes the situation of the inhabitants of Peloponnesus in the following manner:[3] "Now some have affirmed that the nymphs, who officiated in performing the sacred writes, were called *Melissæ*. Of these Mnaseas of Patara gives the following account. They prevailed upon men to relinquish the abominable practice of eating raw flesh torn from living animals, and persuaded them to use the fruits of trees for food. Melissa, one of them, having discovered bee-hives, ate of the honey-combs, mingled the honey with water for drink, and taught the other nymphs to use the same beverage. She called bees Μελισσαι, *Melissæ*, from her own name, and bestowed much care on the management of them. These things," says he, "happened in Peloponnesus; nor is the temple of Ceres honoured without nymphs, because they first pointed out the mode of living on the fruits of the earth, and put an end to the barbarous practice of feeding on human flesh. The same ladies, too, from a sense of decency, invented garments made of the bark of trees."

Progress of their civilisation.

Hecatæus the Milesian, treating of the Peloponnesians, affirms,[4] "that before the arrival of the Hellenes, a race of barbarians inhabited that region; and that almost all Greece was, in ancient times, inhabited by barbarians.[5] "In the earliest times," says Pausanias, "barbarians inhabited most part of the country called *Hellas*."[6] The original Greeks, if we may believe an author of deep research and superior ingenuity,[7] were strangers to all the most useful inventions of life. Even the use of fire was unknown till it was found out and communicated by Prometheus, who is believed to have been one of the first civilizers of mankind. Hence Æschylus introduces Prometheus commemorating the benefits which he had conferred upon mankind by his inventions,[8] in a strain that indicates the uncultivated state of the world prior to the age in which he flourished.

> "Of the human race
> Now hear the tale, how foolish erst they were:
> I taught them thought and exercise of reason:
> If aught they saw before, they saw in vain.
> Hearing, they heard not; all was shapeless dreams
> For a long space of time, at random mixt
> In wild confusion: for they neither knew
> Tile-cover'd houses standing in the sun,
> Nor timber-work; but, like the earth-bred ant,
> They lodg'd in sunless caves dug under ground:
> No certain sign had they of winter cold,
> Nor of the flow'ry spring, or summer store,
> But blindly managed all; till I them taught
> What time the stars appear, what time they set,
> Hard to be scan'd: then arithmetic rare,
> That queen of arts, by dint of patient thought
> Descry'd, I taught them; and how vocal sounds
> From letters join'd arose."

This character, although applied to mankind in general, was in reality that of the most ancient Greeks. These forbidding features had been transmitted to the poet by tradition as those of his ancestors; but he was a Greek, and consequently imputes them to all mankind without distinction.

[6] The Greeks borrowed this contemptuous epithet from the Egyptians. See *Herod.* lib. ii. cap. 158.

[7] Plin. *Hist. Nat.*

[8] *Prometh.* verse 441.

Phoroncus, the son and successor of Inachus,[1] is said to have civilized the Argives, and taught them the use of some new inventions. This circumstance raised his character so high among the savage aborigines of the country, that succeeding ages deemed him the first of men.[2] Pelasgus obtained a similar character, because he taught the Arcadians to live upon the fruit of the *fagus*, to build sheds to shelter them from the cold, and to make garments of the skins of swine.

But what most clearly demonstrates the unpolished character of the ancient Greeks, is the extravagant honours lavished by them upon the inventors of useful and ingenious arts. Most of these persons were advanced to divine honours, and became the objects of religious worship to succeeding generations. The family of the Titans affords a most striking instance of this species of adulation. Jupiter, Juno, Mars, Apollo, Venus, Diana, and others, were sprung of this family. By the useful inventions which these persons communicated to the uncultivated nations of Greece, they obtained such lasting and extravagant honours, that they jostled out the sidereal divinities of the country, and possessed their high rank as long as Paganism prevailed in those regions. To these clear testimonies of the savage character of the original Greeks, others almost without number might be added; but those produced in the preceding part of this inquiry will, we trust, satisfy every candid reader as to the truth of the position advanced.

Arrival of a new colony called *Pelasgi.*

Whilst matters were in this situation with respect to the primitive Jonim or Greeks, a new colony arrived in those parts, which in a few years considerably changed the face of affairs. The people who composed this colony were called *Pelasgi;* concerning whose origin, country, character, and adventures, much has been written, and many different opinions have been held by the learned. It is not our province to enter into a detail of their arguments and systems; and we shall content ourselves with informing our readers, that, according to one opinion, they were natives either of Egypt or of Phœnicia, whilst according to another, and that perhaps the most generally received, they were of Thracian, or, in other words, of Gothic origin. See the article PELASGIANS.

In a very able dissertation upon this subject, it has been proved by many plausible arguments, that this people could not be descendants of the Egyptians nor Phœnicians. The author maintains, that the Pelasgians were a great and numerous tribe; that they overspread all the coast of Asia Minor from Mount Mycale to Troas; that they were at one time masters of nearly all the Asiatic and Grecian islands; that they overran Greece and many of the neighbouring countries; and that all this they effected in less than half a century. These facts he appears to have proved from Homer, Herodotus, Diodorus Siculus, Pausanias, and other Greek authors of approved authenticity. He shows, that they were a civilized race of men, and that they were well acquainted with military affairs, legislation, agriculture, navigation, architecture, letters, &c. He insists, that Phœnicia could not at any given period have furnished such a numerous body of emigrants, even supposing that the whole nation had emigrated, leaving their native country a desert. He believes that this event took place before the invasion of Caanan by the Israelites, and that consequently the Pelasgic migration was not occasioned by that catastrophe. He has shown, we think, by very probable arguments, that the Egyptians in the earliest ages were averse to foreign expeditions, especially by sea; that in fact they hated navigation, and, besides, could be under no temptation to emigrate; and that, whilst they had accustomed themselves to live on small matters, their country was exceedingly fertile and easily cultivated. It appears from Herodotus, that the Pelasgians were not acquainted with the religion of the Zabians, which, he conceives, could not have been the case had they emigrated from either of these countries. He makes it appear, that Herodotus is mistaken when he supposes that the deities of Greece were derived from Egypt. He demonstrates, that the names of the greater part of those divinities are of Phœnician extraction; and this opinion he establishes by a very plausible etymological deduction. He asserts, that if the Pelasgians had been natives of either of the countries above mentioned, it would be absurd to suppose them to have been ignorant of the names and the religious rites of their respective nations. He shows, that the Egyptian and Phœnician colonies, which afterwards settled in Greece, were enemies of the Pelasgians, and either subdued or expelled them the country; which, he imagines, would scarcely have been the case had both parties sprung from the same ancestors. And, having settled these points, he concludes, that the people in question were the progeny of the Arabian shepherds, who, at a very early period, invaded and subdued both Lower and Upper Egypt, and after possessing that country for about a century and a half, were conquered by Amenophis king of Upper Egypt, who drove them out of the country; upon which the fugitives retired to Palestine, where Manetho the Egyptian historian loses sight of them, and either through malice or ignorance confounds them with the Israelites. This writer supposes that these fugitives gradually directed their course towards the western and north-western coasts of Asia Minor, whence they passed over to Greece. Such are the arguments by which the author of the dissertation above referred to supports his hypothesis, and, as we think, proves a negative against the opinion that the Pelasgians were natives of Egypt or Phœnicia.[3]

Introduction of letters.

But be this as it may, nothing seems more certain than that the Pelasgians were the first people who in some degree civilized the savages of ancient Greece. It is not our business at present to enumerate the many useful inventions which they communicated to the Greeks, at that time worse than barbarians. We deem it absolutely necessary, however, as an introduction to our subject, to hazard a few conjectures on the language and letters of those adventurers; a point strictly connected with the subject which is about to come under consideration.

Whether we suppose the Pelasgians to have been the offspring of the Phœnicians, Egyptians, or Arabian shepherds, it will make little difference as to their language; because every man of learning and research is convinced that those three nations, especially at the early period in question, spoke a dialect of the Hebrew. The Pelasgians, then, must have spoken a dialect of that language when they arrived in Greece. Perhaps it might have undergone several changes, and acquired some new modifications, during the many years which had passed since they began to be a separate nation, and in the course of numerous peregrinations. Some monuments still extant prove this fact beyond all contradiction. As these people incorporated with the aborigines of Greece, the remains of the original language of mankind, or at least as much of it as had been retained by them, gradually coalesced with that of the new settlers. From this, we think, it is obvious, that prior to the arrival of the new colonists from the East, the language now current amongst the two united tribes must have been a dialect of the Phœnician, Arabian, or Hebrew. But be this as it may, Herodotus[4] affirms that the

[3] If our readers should wish to know more of this subject, they may consult Gebelin's *Preliminary Discourse to his Greek Dictionary*, Lord Monboddo's *Inquiry into the Origin and Progress of Language*, vol. i. towards the end, and Mr. Bryant's *Analysis of Ancient Mythology*, passim.

[4] Lib. i. cap. 59.

Pelasgians in his time spoke a barbarous language, quite unintelligible to the modern Greeks.

The reason of this difference between the language of the Hellenes or Greeks in the age of Herodotus, and that of the remains of the Pelasgians at that period, may easily be conjectured. Previously to the era of that historian, the Greek language had, from time to time, undergone many changes, and received vast improvements; whereas, on the contrary, that of the remnant of the Pelasgians, who were now reduced to a very low state, had remained stationary, and was then just in the same predicament in which it had been a century after their arrival in the country.

Since the Pelasgians, as was above observed, were a people highly civilized and well instructed in the various arts at that time known in the eastern world, they must have been skilled in agriculture, architecture, music, and other arts.[1] The presumption then is that they could not be unacquainted with alphabetical writing. This most useful art was well known in the countries from which they emigrated; and of course it is impossible to imagine that they did not export it as well as the others above mentioned. Diodorus Siculus imagines[2] that the Pelasgians knew not the use of alphabetical letters, but that they received them from Cadmus and his Phœnician followers; and that these letters were afterwards called *Pelasgic*, because the Pelasgians were the first people of Greece who adopted them. But this account must be placed to the score of national vanity, since soon afterwards he acknowledges that Linus wrote the exploits of the first Bacchus and several other romantic fables in Pelasgian characters;[3] and that Orpheus, and Pronapides the master of Homer, employed the same kind of letters. Zenobius likewise informs us that Cadmus slew Linus for teaching characters different from his.[4] These letters could be none other than the Pelasgic.[5]

Pausanias, in his Attics, relates, that he himself saw an inscription upon the tomb of Coræbus, who lived at the time when Crotopus, who was contemporary with Deucalion, reigned as king of the Argives.[6] This inscription then was prior to the arrival of Cadmus; and consequently letters were known in Greece before they were introduced by that chief. It likewise appears from Herodotus himself, that the Ionians were in possession of alphabetical characters before the landing of the Phœnicians. "For," says he, "the Ionians having received letters from the Phœnicians, changing the figure and sound of some of them, ranged them with their own, and in this manner continued to use them afterwards."[7] If, then, the Ionians ranged the Phœnician characters with their own, it is obvious that they had alphabetical characters of their own.[8]

Besides these historical proofs of the existence of Pelasgian characters, monuments bearing inscriptions in the same letters have been discovered in several parts of Greece and Italy, which place this point beyond the reach of controversy. What these characters were may easily be determined. As the Pelasgians emigrated from Arabia, the presumption is that their letters were Phœnician. They are said by Dr. Swinton to have been only thirteen in number, whereas the Phœnician alphabet consists of sixteen. The three additional letters were probably invented by the latter people after the Pelasgians had left the countries of the East. The Phœnician letters imported by the Pelasgians were, no doubt, of a very coarse and clumsy contexture, unfavourable to expedition in writing, and unpleasant to the sight. Besides, the Phœnician characters had not as yet received their names; and accordingly the Romans, who derived their letters from the Arcadian Pelasgians,[8] had no names for theirs. The probability is, that prior to this era the Pelasgian letters had not been distinguished by names. These were of course no other than the original letters of the Phœnicians in their first uncouth and irregular form; and for this reason they easily gave way to the Cadmean, which were more beautiful, more regular, and better adapted for expedition.

The Thracians a powerful nation.

Hitherto we have seen the Pelasgians and the Ionim incorporated, living under the same laws, speaking the same language, and using the same letters. But another nation, and one too of great extent and populousness, had at an early period taken possession of a considerable part of the country afterwards distinguished by the name of *Hellas* or Greece. The Thracians, according to the father of Grecian history, were a great and mighty nation, indeed inferior to none except the Indians.[9] This people, at a very early period, had extended their conquests over all the northern parts of that country. They were, in ancient times, a learned and polished nation. From them, in succeeding ages, the Greeks derived many useful and ornamental sciences. Orpheus the musician, the legislator, the poet, the philosopher, and the divine, is known to have been of Thracian extraction.[10] Thamyris and Linus were his disciples, and were highly respected amongst the Greeks for their learning and ingenuity. That this people spoke the same language with the Greeks, is abundantly evident from the connection between the latter and these old Thracian bards. The Thracian language, then, whatever it was, contributed in a great proportion towards forming that of the Greeks. From the remains of the Thracian dialect there appears to have been a very strong resemblance between it and the Chaldaic. This position we could readily support by the most plausible etymological deductions, did the limits prescribed us in this article admit of such a discussion. It appears, however, that the Thracians, the Getæ, and the Daci or Davi, spoke nearly the same language.[11] The Goths, so much celebrated in the annals of the lower empire, were the descendants of the Getæ and Daci, and consequently must have retained the dialect of their ancestors. The reader, therefore, must not be surprised, if in tracing the materials of which the Greek language is composed, we should sometimes have recourse to the remains of the Gothic.

Greek composed of three dialects.

We have now discovered three branches of the Greek language; that of the Ionim or Aborigines, that of the Pelasgic tribes, and that of the Thracians. These three, we imagine, were only different dialects of the very same original tongue. This assertion might easily be proved by the comparison of a great number of words taken from the two last, were this a proper place for such a discussion.

Cadmus.

Some centuries after the arrival of the Pelasgians, Cadmus, an Egyptian by birth,[12] and a sojourner in Phœnicia, arrived in Bœotia with a multitude of followers; and this chief with his countrymen introduced letters and several other useful improvements into the country in question. As these immigrants were natives of Phœnicia and its environs, their alphabet was that of their native country, consisting of sixteen letters. That the Phœnician alphabet was nearly the same with the Samaritan and Hebrew, has so often and so clearly been demonstrated by the learned that it would be altogether superfluous to insist upon it in the present inquiry. The Phœnicians, as is generally known, wrote from right to left, and the old Grecian characters, inverted, exactly resemble the Phœnician.

Greek Language.

Cadmean letters.

The names of the Cadmean characters are Syrian,[1] which shows the close resemblance between that language and the Phœnician. They stand thus, viz. *alpha, beta, gamla, delta,* &c. The Syrians used to add *a* to the Hebrew words; hence alph becomes alpha, beth, betha or beta, and so on. In the Cadmean alphabet we find the vowel letters, which is an infallible proof that such was the practice of the Phœnicians in the age of Cadmus; and this circumstance also furnishes a presumption that the Jews did the same at the period in question. After all, it is evident that the oldest Greek letters, which are written from right to left, differ very little from those of the Pelasgians. The four double letters θ, φ, ξ, χ, are said to have been added by Palamedes about twenty years before the war of Troy. Simonides is generally supposed to have added the letters ζ, η, ψ, though it appears by ancient inscriptions that these letters were used before the days of Palamedes and Simonides.

The old Ionic character.

In the year 1456 seven brazen tables were discovered at Eugubium, now Gobbio, a city of Umbria in the Apennines, five of which were written in Pelasgian or Etruscan characters, and two in Latin. The first of these tables is believed to have been composed about one hundred and sixty-eight years after the taking of Troy, or twelve hundred and six years before Christ. By comparing the inscription on these tables with the old Ionic characters, the curious have been enabled to discover the resemblance. The old Ionic character written from right to left continued in general use for several centuries. It was composed of the Cadmean and Pelasgian characters, with some variations of form, position, and sound. The Athenians continued to use this character till the year of Rome 350. The old Ionic was gradually improved into the new, and this quickly became the reigning mode. But after the old Ionic was laid aside, the (Βουστροφηδον) Bustrophêdon, came into practice, which goes backwards and forwards as the ox does when ploughing.[2] They carried the line forward from the left, and then backward to the right. The words were all placed close together, and few small letters were used before the fourth century. Such of our readers as wish to know more of letters and alphabets, may consult Chishul, Morton, Postellus, Montfaucon, Gebelin, Astle, and others. For our own part we are chiefly concerned at present with the Phœnician and Cadmean systems; and on these perhaps we may have dwelt too long.

The Greek alphabet derived from the Phœnician.

Having now, we hope, sufficiently proved that the Greek alphabet was derived from the Phœnician, in order to convince our readers of the certainty of our position, as it were by ocular demonstration, we shall annex a scheme of both alphabets, to which we shall at the same time subjoin some strictures upon such letters of the Greek alphabet as admit of any ambiguity in their nature and application.

Α, *alpha*, had two sounds, the one broad like *a* in the English word *all;* the other slender, as *e* in *end, spend, defend.* The Hebrews certainly used it so, because they had no other letter to express that sound; the Arabs actually call the first of their alphabet *elif;* and they as well as the Phœnicians employ that letter to express both the sound of A and E promiscuously. The Greeks call their letter E ε-ψιλον, that is E slender, which seems to have been introduced to supply the place of A slender. Η, *êta*, was originally the mark of the *spiritus asper*, and no doubt answered to the Hebrew ה. It is still retained in that capacity in the word Ηεκατον, and in other with the *spiritus asper* beginning books, chapters, sections, &c. Ε originally marked both the sound of Εψιλον and Ητα; that is, it was sometimes sounded short, as at present, and sometimes long, where it is now supplied by Η. As it was found convenient to distinguish these two different quantities of sound by different letters, they adopted Η, the former *spiritus asper*, to denote the long sound of Ε, and substituted the present *spiritus asper* [ʽ] in its place. Ι, *iota*, is the Hebrew or Phœnician *jod* or *yod.* It appears to have originally served the purpose both of iota and ypsilon. It had two different sounds; the one broad and full, the other weak and slender. The latter had the sound of the modern ὐψιλον. That this was actually the case, appears from several monumental inscriptions; and upon this depends the variation of some cases of the demonstrative pronoun and of the second declension. Ο, *omicron*, or small *o*, in the original Greek had three different sounds. It sounded *o* short, as at present; and likewise *o* long, now denoted by Ω or large O. It likewise marked the sound of the improper diphthong *ου*, sounded like the English diphthong *oo.* The Ω was taken from the Phœnician wau or *V.* Υ, *ypsilon*, we have observed before, was adopted to supply a mark for the sound of I slender. Ζ, *zeta*, is compounded of δ and ς. Dionysius of Halicarnassus, however, informs us, that this letter should be pronounced σδ, according to the Doric plan. Θ, *theta*, was not known in the old Greek. It is compounded of τ and the *spiritus asper*, both which were of old written separately, thus TH. Ξ, *xi*, is compounded of γς, κς, χς. These letters, too, were originally written separately. Φ, *phi.* This letter is compounded of β, π, and the *spiritus asper;* thus, BH, PH. X, *chi*, like the foregoing, is compounded of γ, κ, and the *spiritus asper* as above. Ψ, *psi*, like some of the rest, is made up of βς, πς, which, too, were originally written in separate characters.

These observations are thrown together purely for the use of students who may not choose to inquire into the *minutiæ;* and we regret that the nature of the work does not permit us to extend our researches to greater length. Every language, we believe, was originally composed of inflexible words; and the variations which now distinguish nouns and verbs were the effects of progressive improvements. What might have been the state of the Greek language with respect to these variations in its original form, it is not now possible to discover. That it was rude and irregular, will not, we imagine, be controverted. One of the first attempts towards forming the variations, now denominated declensions and conjugations, would probably be made upon the demonstrative article and the substantive verb. This observation will be found to hold good in most polished languages. In the Greek tongue, it was evidently the method employed.

Origin an flexion of the article

The original Greek article was imported from the East. It was the Hebrew or Phœnician ה *ha.* This particle sometimes signifies *one*, and sometimes it answers to our demonstrative *the;* and both in its adverbial and demonstrative capacity it imports demonstration. In the earliest stages of the two oriental languages, however, it was probably written apart, as *ha-melech*, the king; but in process of time it came to be joined with the following word, as *Hammelech.* From this we think the Greek article was deduced; and it is still retained in the Doric dialect in its pristine character. The difference between *ho* and *ha* in the eastern language is nothing. Here then we have the articles ὁ masculine, and ἁ feminine. Upon these several changes were superinduced, to render them more useful for the purposes of language; but for such changes we know of no archetype.

The Greeks then having adopted the Hebrew, or Phœnician, or Chaldaic article *ha*, and changed it into *ho* for the masculine, seem to have arranged its variations in the following manner:—

	Sing.	*Plu.*
Nom.	ὁ	ὁι
Gen.	ὁυ	ὡν
Dat.	ὁι	ὁις
Acc.	ὁν	ὁυς

---

[1] Scaliger

[2] Pausan. lib. viii. cap. 17.

ts use in
he flexion
f nouns.

In the earliest stages of the Greek language, ι and υ were sounded in the same manner, or nearly so, as was observed above. The accusative was at first like the nominative; but for distinction's sake it was made to terminate in ν, which letter was likewise adopted to characterise the genitive plural; and ς was annexed to the dative plural, to distinguish it from the dative singular. The radical word was still without inflexion. When the article was inflected in this manner, the process stood as follows. We take λογος as an example.

	Sing.	*Plu.*
Nom.	ὁ λογ *speech.*	ὁι λογ *speeches.*
Gen.	ὁυ λογ *of speech.*	ὡν λογ *of speeches.*
Dat.	ὁι λογ *to speech.*	ὁις λογ *to speeches.*
Acc.	ὁν λογ *speech.*	ὁυς λογ *speeches.*

In this arrangement our readers will observe, that at the time under consideration, ω was not yet introduced; and therefore ομικρον or little ο was the same letter in the genitive plural as in the accusative singular; but in the latter case it was sounded long by way of distinction.

The article *ha*, which is still retained in the Doric dialect, was varied as follows:—

	Sing.	*Plu.*
Nom.	ἁ	ἁι
Gen.	ἁς	ὡν
Dat.	ἁι	ἁις
Acc.	ἁν	ἁς

These variations differ somewhat from those of the masculine type; and they were no doubt made for the sake of distinction, as is usual in such cases. We shall now give an example of the feminine as it must have stood before variations were introduced, and for this purpose shall employ τιμη.

	Sing.	*Plu.*
Nom.	ἁ τιμ *honour.*	ἁι τιμ *honours.*
Gen.	ἁς τιμ *of honour.*	ὡν τιμ *of honours.*
Dat.	ἁι τιμ *to honour.*	ἁις τιμ *to honours.*
Acc.	ἁν τιμ *honour.*	ἁς τιμ *honours.*

Afterwards, when the Chaldean article *da* was adopted for the neuter gender, the letter ד or *d* was changed into τ, and prefixed to it; and then the Greeks, who, in their declension of adjectives, always followed the neuter gender, began to prefix it to the oblique cases.

In this manner, we think, the Greek nouns stood originally; the only change made being that upon the article. At length, instead of prefixing that word, and expressing it by itself, they found it convenient to affix a fragment of it to the noun, and so to pronounce both with more expedition. Thus, ὁς-λογ e. g. became λογ-ὁς, ὁυ λογ became λογ ὁυ, and of course λογος and λογου, &c. The *spiritus asper*, or rough breathing, was thrown away, in order to facilitate the coalition. Nouns of the neuter gender were distinguished by using ν instead of ς; and in oriental words the Greeks often change ς into ν, and *vice versa*. In this case the Greeks seem to have copied from an eastern archetype. In Hebrew we find an arrangement exactly similar. To supply the place of the pronouns possessive, fragments of the personals were affixed. Thus, the Hebrews wrote *ben-i*, my son, instead of *ben-ani*, and *debir-nu*, our words, instead of *debir-anu*. The persons of their verbs were formed in the same manner. In this way, in our opinion, the variations of the first and second declensions were produced.

of its
es.

After a very considerable number of their nouns were arranged under these two classes, there remained an almost indefinite number of others which could not conveniently be brought under these arrangements, because their terminations did not readily coalesce with the articles above mentioned. These, like nouns of the neuter gender, were in a manner secluded from the society of the two other classifications; and it is probable that they for a long time continued indeclinable. At last, however, an effort was made to reduce them into a class as well as the others. All these excluded nouns originally terminated with *sigma*, as appears from the genitives as they stand at present. By observing this case, then, we will be readily conducted to the termination of the pristine word or root. The genitive always ends in ος, which termination is formed by inserting ο between the radical word and ς. By throwing out ο we have the ancient nominative. Thus, Τιταν, genitive Τιτανος; leaving out ο we have Τιτανς, the original inflexible termination. Λητω, genitive Λητοος; throw out ο and you have Λητος. Παλλας, genitive Παλλαδος; take away ο and there remains παλλαδς. Ορνις, genitive Ορνιθος; by throwing out ο we have Ορνιθς. Αναξ, genitive Ανακτος, Ανακτς. Κρατος, genitive Κρατεος, Κρατης; originally Κρατος, because primarily ε had the sound of η, as was observed above. Μελι, genitive Μελιτος, Μελιτς. Ειδος, genitive Ειδεος, Ειδες, the old noun. In short, the genitive is always formed by inserting ο immediately before ς, which is always the termination of the nominative; and by this rule, we may easily discover the noun as it existed in its original form.

The dative of this declension was closed with ι *ascriptum*; the same thing occurred in that of the second, namely, ι *subscriptum*. The accusative commonly terminate with α; but was originally ended with ν. The Romans imitated the Æolic dialect, and they commonly ended it with *em* or *im*. The Greeks perhaps in this imitated their progenitors, for α was their favourite vowel. The nominative plural ended in ες, which nearly resembles the English plural, and was probably borrowed from the Thracians. The genitive plural in all the declensions ends in ων; the dative ends in σι, the σ being inserted to distinguish it from the dative singular. When a strong consonant, which would not easily coalesce with ς, comes immediately before it, that consonant is thrown out to avoid a harsh or difficult sound. The result then is; the cases of nouns of the first and second declensions consist of the radical word with fragments of the articles annexed, and these were the first classifications of nouns. The other nouns were left out for some time, and might be denominated *neuters;* but at length they too were classified, and their variations formed as above. In this process the Greeks deviated from the oriental plan; for the people of the East always declined their nouns by particles prefixed. Whether the Greeks were gainers by this new process, we will not pretend positively to determine. We are inclined to imagine, however, that they lost as much in perspicuity as they gained in variety.

Greek ablative.

It is generally believed that the Greeks have no ablative; but to this opinion we cannot assent. It is true, that the dative, and what we would call the *ablative*, are always the same; yet we think there is no more reason to believe that the latter is wanting in Greek, than that the ablative plural is wanting in Latin, because in that language both these cases are always alike.

Genders.

In the eastern languages there are only two genders, analogous to the established order of nature, where all animals are either male or female. But as the people of the East are, to this day, strongly addicted to personification, they ranged all objects of which they had occasion to speak, whether animate or inanimate, under one or other of these two classes. Hence arose what is now called the masculine and feminine genders. The orientals knew nothing whatever of a neuter gender, because all objects were comprehended under the two foregoing classes. The Phœnician feminine was formed from the masculine, by adding אה, *ah*. In this the Greeks in many cases imitated them. The Greeks and Latins left a vast number of substantives, like a kind of outcasts, without reducing them to any gender; and this proceeding gave rise to the neuter gender, which imports, that such substantives were of neither gender; a circumstance which has the appearance of a defect, or rather a blemish, in both. Sometimes, too, they made words neuter, which, according to the analogy of grammar, ought to have been either masculine or femi-

Greek Language.

nine; and again, they ranged words under the masculine or feminine, which by the same rule ought to have been neuter. In short, the doctrine of generical distribution seems to have been very little regarded by the fabricators of both tongues. The beauty which arises from variety seems to have been their only object.

Further observations on the article.

The use of the article in the Greek language is, we think, rather indeterminate, being often prefixed to proper names, where there is no need of demonstration or generical distinction. On the contrary, it is often omitted in cases where both the one and the other seem to require its assistance. In short, in some cases it seems to be a mere expletive. Though both Lord Monboddo and Mr. Harris have treated of this part of speech, neither the one nor the other has ascertained its proper use.[1] We know not any objection to the early use of articles amongst the Greeks so plausible as the total neglect of them amongst the Romans. But it ought to be considered, that after the flexions had been introduced, the use of the article was in a great measure neglected. Accordingly, Lord Monboddo observes that it is very seldom used as such by Homer, but commonly instead of the relative pronoun ὁς, ἡ, ὁ. Thus it would appear, that at the time when the Roman language was reduced to the Grecian standard, the article was not commonly used by the Greeks; and consequently the Latins never employed it. There can be no doubt that the pronoun *who*, in the northern languages, is the same with the Greek ὁ, and the Hebrew *hua*. This amongst the northern nations is always a relative, which affords a presumption that the Greeks originally used the article in the same manner as we do at present. The fact is, that the articles having once got into vogue, were often positively used as mere expletives to fill up a gap; and, on the other hand, when there was no occasion for pointing out an object, fully determined by the tenor of the discourse, it was often omitted.

Adjectives.

In forming adjectives, they followed the same plan that they had done with substantives. Their great effort was to make their adjectives agree with their substantives in gender, in number, and in case. This arrangement improved the harmony of speech; and nothing could be more natural than to make the word expressing the quality correspond with the subject to which it belonged. As adjectives denote qualities, and are thus susceptible of degrees, nature taught them to invent marks for expressing the difference of these degrees. The qualities may exceed or fall below each other by almost numberless proportions; it was, however, found convenient to restrict such increments and decrements to two denominations. The positive is, properly speaking, no degree of comparison at all; therefore we need only point out the formation of the comparative and superlative. The former is generally thought to have been fabricated, by first adding the Hebrew word יהר, *excellent*, to the positive, and then affixing the Greek termination ος; and the latter, by affixing the Syrian word *tath* and the syllable ος, in the same manner.

Greek numerals.

Every nation, even the most uncivilized, must have early acquired the notion of number. Numerical characters and names are the same in many different languages. These terms were discovered, and in use, long before grammar attained to any perfection; and therefore they remain either inflexible or irregular. The first way of computing amongst the Greeks was by the letters of the alphabet; so that Α signified *one*, and Ω *twenty-four*; in this manner the rhapsodies of Homer are numbered; and so are the divisions of some of the Psalms, as is generally known. But a more artificial plan of computation was obviously necessary. They therefore divided the letters of the alphabet into *decades* or tens, from Α to Ι = 10. To express the number 6, they inserted ϛ; so that by this means the first decade amounted to 10. In the next decade every letter increased by tens, and so Ρ denoted 100. In this decade they inserted ϟ κοππα = 90. In the third, every letter rose by 100; so that ϡ) σανπι = 900. By inserting these three Phœnician characters they made their alphabet amount to 900. To express chiliads or thousands, they began with the letters of the alphabet as before; and to make the distinction, they placed a dot under each character, as the units, tens, hundreds, were distinguished by an acute accent over them.

But in monumental inscriptions, and also in public instruments, a larger and more lasting numerical character was fabricated. They began with Ι, and repeated that letter till they arrived at Π = 5. This is the first letter of πεντε, *five*. They then proceeded, by repeating Ι till they came to 10 Δ, the first letter of δεκα, 10. Then they repeated Δ over and over, so that four Δ = 40. To express 50, they inclosed Δ in a sort of open square $|\bar{\Delta}|$ = 50, $|\bar{H}|$ = 500, $|\bar{M}|$ = 50,000, &c. Often, however, Χ signifies 1000, and then we have δις Χιλιοι, 2000; τρις Χιλιοι, 3000; and so of the rest.

Pronouns.

The term pronoun signifies a word employed instead of a noun or name; and indeed the personal pronouns are really such. This needs no explication. The pronoun of the first person is one of those words which have continued invariable in all languages; and the other personals are of the same character. The relatives, possessives, demonstratives, and gentiles, are generally derived from these, as may be discerned by a very moderate adept in the language. Our readers will therefore, we hope, easily dispense with our dwelling upon this part of speech.

Greek verbs.

In most ancient languages, verbs, according to the order of nature, have only three tenses or times, namely, the past, the present, and the future. The intermediate tenses were the invention of more refined ages. The Greek, in the most early periods of their language, had no other tenses than those above mentioned. The manner of forming these we shall endeavour to point out, without touching upon the nature of the rest, since an idea of them may be acquired from any common grammar.

It has already been observed, that the flexion of nouns of the first and second declensions are formed by annexing fragments of the articles to the radical words; and that the variation of the tenses was produced by joining the substantive verb, according to the same analogy. Every Greek verb was originally an inflexible biliteral, triliteral, quadriliteral or dissyllabic radix; and the variations were formed, a long while afterwards, in the manner above intimated.

The Greeks derived their substantive or auxiliary verb, from the Phœnician or Chaldean verb היה, *fuit*, which verb, taking away the gentle aspiration from both beginning and end, actually became ει. This form the Greeks brought along with them from the East, and manufactured after their own manner, which appears to have been thus:

Pres. εω, εες, εε, εομεν, ϝετε, εοσι,
Cont. ω, εις, ει, ουμεν, ειτε, ουσι,
Fut. εσω, εσεις, εσει, εσομεν, &c.

We here place οσι in the third person plural, because for many centuries ὀμικρον supplied the sound of the diphthong ου. By these variations it will appear that the radical verb was rendered capable of inflection. We have observed that Greek verbs were a collection of biliteral, triliteral, or quadriliteral, radical words. The following may serve as examples: τι, λεγ, Μαρ, τυπ, φαν, ταν, ραπ, Δαμ, Δηλ, Δεικ. These radicals are taken at random; and we believe that a student of Greek, by adding the terminations, will readily find them to be all significant verbs. With these radicals, then, and the substantive verb, the present and future tenses were formed.

The second future.

But it is now generally admitted that the modern was not the original present tense of the verb. The second, or Attic future, appears evidently to have been the most ancient present. When the language was improved, or rather in the course of being improved, a new present was invented, derived indeed from the former, but differing widely from it in its appearance and complexion. Upon this occasion, the old present was degraded, and instead of intimating what was *doing at present*, was made to import what was immediately to be done hereafter. By this means, γραφεω, contracted in γραφῶ, *I am writing*, came to intimate, *I am just going to write*. This change was probably made for the sake of enriching the language, and giving variety and energy. Thus, τυπεω contracted τυπῶ became τυπτω, τικῶ, τικτω, &c. According to this theory, we find, that such verbs as have now no second future retain their original form, only the circumflex has been removed in order to accommodate them to the general standard. Grammarians have chosen the three characteristic letters of active verbs from the present, first future, and perfect: but the true characteristic of the original verb was that of the present second future. Many verbs are now destitute of this tense, because since the invention of the new present, the former one has fallen into disuse.

---

[1] See *Origin and Progress of Language*, vol. ii. p. 53. *Hermes*, p. 214, *et seq.*

rmation the mo- n pre- t.

Let us now take the verb λενω. *dico*. in order to make a trial; and let us write the radix and tne auxiliary, first separately, and then in conjunction. Thus, λεγ-εω, λεγ-εες, λεγ-εε, λεγ-εομεν, λεγ-εετε, λεγ-εοσι. Then we shall have contracted λεγῶ, λεγεῖς, λεγεῖ, λεγοῦμεν, λεγεῖτε, λεγουσι. Here, we believe, every thing is self-evident. The English of this would be, "Saying, *I am*, saying *thou art*, saying *he is*," &c. At first the radix and the auxiliary were pronounced separately, as we do our auxiliary verbs in English, and would have been written in the same manner if words had been then distinguished in writing.

st fu- t.

The present first future occupied the same place which it now does, and concurred in its turn to complete the future in conjunction with the radix or root. That the substantive verb was inflected in the manner above explained, is obvious from its future middle εσομαι, and also from the future of the Latin verb *sum*, which was of old *eso*, *esis*, &c. Verbs in λω, μω, νω, ρω, often take σω in the first future.[1] Verbs in λω and ρω assume σ by analogy, as κελλω, κελσω, Eurip. *Hecub.* v. 1057. κελσαι, Hom. *Odyss.* x. v. 511. τελλω, τελσω, *unde* τελσον, *Il.* x. v. 707. ορω. ορσομεν, Pind. *Nem. Od.* 9. Duodec. 2. τειρω, τερσει, Theoc. *Idyll.* 22. v. 63. In fine, the Æolic dialect after the liquids often inserted σ.

It must be observed, that the Greeks, in order to accelerate the pronunciation, always throw out the ϵ and ο, except in verbs ending in αω, εω, οω, where they generally change them into η and ω. When the last letter of the radix can coalesce with σ after ϵ is thrown out, they transform it, so as to answer that purpose; but if not, they sometimes throw it out. We shall once more take λεγω as an example:

λεγ-εσω, λεγ-εσεις, λεγ-εσει, &c.

Throwing out ϵ, it would stand as λεγ-σω, λέγ-σεις, λεγ-σει, and by changing γs into ξ it becomes λεξω. Δθ and σ cannot coalesce with σ, therefore they are thrown out. Thus, Αδω, first future ασω; πληθω, first future πλησω; ἀνυτω, ἀνυσω, and the like.

Pr ite ten

These are the general rules with respect to the formation of the present and future of active verbs in the earliest stages of the Greek language. The limits prescribed to us will not allow us to pursue these conjectures; but the reader may, if he thinks proper, carry them a great way. The preterite tense falls next under consideration. If we may trust to analogy, this, as well as the other two, must have owed its confirmation to the radix of the verb, and some other word fitted to eke out its terminations. It has been thought by some critics, that this addition was taken from the Hebrew word חית; and we should be of the same opinion were it not that another auxiliary presents itself nearer home, and appears much more congruous to such a purpose. Perhaps, indeed, the people from whom we suppose it to have been borrowed, derived it from the eastern nations. We have already observed, that the Thracians were masters of a great part of Greece in the most remote ages. At that time they were a polite and learned people; and from them a considerable part of the Greek language was derived. If, therefore, we should find a word in their language employed for the same purpose, and accommodated to coalesce with the radical verb, we would feel ourselves very much inclined to prefer such a word.

The auxiliary verb.

The word *ha* pervades many different languages as an auxiliary verb. From it we have the Italian *ho*, the Spanish *he*, the French *ai*; and in one shape or other it appears in all the German and Scandinavian dialects. It is the Gothic auxiliary; and, we believe, it forms the termination of the perfect active of the first conjugation in the Latin tongue. For there *am* is the radix of *amo*, which has in the preterite *am-avi*, *amavi*, and in the preterperfect *am-hav-eram*, *amaveram*, compounded of *am*, *hav*, and *eram*, the imperfect of the indicative of the substantive verb. This process, in the formation of the preterite of Latin verbs, will scarcely be questioned, and forms certainly a presumptive proof that the Greeks pursued the same course. From this verb is likewise derived the Latin *habeo*, by changing *v* and *b*, which are indeed the same letter. Our readers, after this detail, will not be surprised if we should now hazard a conjecture, and declare it to be our opinion, that this same Gothic auxiliary *ha* is actually the additional part of the preterite of Greek verbs, indeed that part upon which the conjugation depends.

In forming this combination between the radix and the auxiliary, the Grecks were obliged to employ several devices. As often as the last letter of the radix could not unite with the aspirate in *ha*, they metamorphosed it into one of the double letters, which are capable of coalescing with it. In the verb λεγω, γ was changed into χ; thus λεγ *ha* became λεχα, τυπτω preterite τυπ *ha*, was combined into τυφα. In verbs having a radix which would not admit of this conjunction, they hardened the *h* into κ, as in τιω, preterite τι-κα, ἀκου-κα. Many other ways were contrived to facilitate this re-union; but these are detailed in every Greek grammar, and so need not be mentioned. What has been said with respect to this configuration, we offer as a pure conjecture, without the most remote intention of obtruding it upon our readers.

If it be admitted, that the auxiliary *ha* formed the conjugating termination of the active verb amongst the Greeks, it will likewise be admitted, that the radical verb and the other formed originally two distinct words, and that, according to this scheme, the preterite would proceed thus: λεγ *ha*, said *I have*; λεγ *has*, said *thou hast*; λεγ *he*, said *he hath*, and so on. This process appears to us rational, elegant, and advantageous. The pluperfect was not then invented, and therefore it does not come under our consideration. The other tenses were all deduced from those described; and in forming these intermediate distinctive tenses, we believe that both critics and grammarians, and perhaps philosophers too, were employed. See the article GRAMMAR.

The eastern nations have diversified their verbs, by affixing fragments of the personal pronouns to the radix, by which means they gained only the advantage of exhibiting the genders of the persons engaged in being, acting, and suffering; but a perpetual repetition of these became unavoidable. The Greeks, by their artificial combination of the radix with the two auxiliaries, avoided the necessity of repeating their personal pronouns, as we and the other modern inhabitants of Europe are now obliged to do; and at the same time, by diversifying the terminations of their nouns and verbs, they wonderfully improved the beauty and harmony of their language. The arrangement above insisted on is so very different from that of the orientals, and so entirely Gothic, that we think there can be no doubt of the Greeks having borrowed this device from the Thracians. Every person who is moderately acquainted with the Greek language will, upon examination, discover a wonderful coincidence between the structure, idioms, and phraseology, of the English and the Greek; and so many congenial features must engender a strong suspicion that there once subsisted a pretty intimate relation between them.

---

[1] See *Fœd. Cret. ap. Marm. Oxon.* lib. 87.

In the preceding deduction, we have found ourselves obliged once more to differ from the very learned author of the *Origin and Progress of Language*. As we took the liberty to question his originality of the Greek language, and at the same time presumed to attack the goodly structure raised by philosophers, critics, and grammarians; so we now totally differ from that learned writer respecting his theory of the creation of verbs out of the inhabile matter of αω, εω, &c. This whole fabric, in our opinion, leans upon an insecure foundation. The apparatus of intermediate tenses, of augments, derivation of tenses, with their formation, participles, idiomatical constructions, and other essentials or appendages, we omit, as not coming within the scope of this disquisition.

Derivation and formation of the middle voice.

The derivation and formation of the middle and passive voices, would certainly afford matter of curious speculation; but the labour necessary to investigate this connection would greatly overbalance any benefit to be expected from the exposition of it. However, in order to complete our plan, we shall subjoin a few strictures respecting the formation of the middle voice, which, in our opinion, was immediately formed from the active. We have already seen, that the active voice, in its original state, was formed by annexing fragments of the substantive or auxiliary verb to the radix. The same economy has been observed in fabricating the flexible parts of the verb of the middle voice. To demonstrate this, we shall first conjugate the present tense of the auxiliary passive upon the principles above laid down.

Present, Εομαι, εεσαι, εεται, εομεθα, εεσθε, εονται. Such was the passive present of the auxiliary. We shall now take our example from the verb τυπτω; second future τυπ-εομαι, *struck I am*, τυπ-εεσαι, *struck thou art*, τυπ-εεται, *struck he is*, &c. contracted τυπουμαι, τυπη, τυπειται. The conjunction and formation here are obvious. Perhaps, in the second person, σ was inserted, which, however, is thrown out in the process of the persons. The future middle is clearly formed, by affixing the future-passive of the verb ἑω, only as η was introduced into the language for ε long, it was generally[1] substituted instead of that vowel in verbs ending in αω and ω, and ω for ο in verbs ending in οω; the two vowels ε and ο being originally long as well as short, till η was adopted to denote the long sound of the former, and ω that of the latter. In many verbs, before the conjunction of the radix and auxiliary, ε was thrown out. Thus, τυπ-εσομαι, became τυψομαι, λεγ-εσομαι, λεξομαι, &c.

Pl. CCCCIX.

The preterite was deduced from that of the active by a very slight variation, so trifling, indeed, that it need not be mentioned; only we may observe, that the aspirate *h* is never retained in this tense, which originally seems to have been the only distinguishing character by which that tense of the middle voice differed from the same tense of the active.

From the strict analogy between the mode of forming the three primary tenses of the active and middle voice, we are led to suspect that what is now the middle was originally the passive voice. The immediate formation of the former, by annexing the passive auxiliary, is obvious. The middle voice still partakes of the passive signification, since it has sometimes a passive, though more frequently an active sense. There are several parts of the present passive quite analogous to the same tenses in the middle; and, lastly, it is the common progress, in the course of improvement, to proceed step by step, and by approximation. What is most simple and easy is the first object, then succeeds what is only a little more difficult, and so on until we arrive at the last stage, when human ingenuity can proceed no farther. Now, it will readily be admitted, that the passive voice is much more embarrassed and intricate in its texture than the middle; and, therefore, the former should have been posterior in the order of time to the latter.

We are very well aware, that the learned Kuster, and indeed many other moderns, deeply skilled in the origin, progress, and structure, of the Greek language, have thought otherwise. The general opinion has been, that the Greek middle voice answered exactly to the Hebrew conjugation *hithpahel*, and in its pristine signification imported a reciprocality, or when the *agent acts upon itself*. But for our part, we only intended a few hints upon the subject, which our learned readers may pursue, approve, or reject, at pleasure.

Of the passive voice.

Next, if we might pretend to investigate the formation of the passive voice, we should imagine that the modern present was formed from the ancient one, by inserting such letters as were found necessary for beauty, variety, and energy; the first future from the second future middle of the verb τιθημι, once ϑεω. This future is θησομαι, and, joined to the radix, always occupies that place, τι-θησομαι, τελεθησομαι, φλεχθησομαι, τυφθησομαι, and so of the rest; but whether μαι, σαι, ται, which occur so frequently as the terminations of the middle and passive voices, are fragments of some obsolete verb, we will not pretend to determine. From verbs in αω, εω, οω, υω, are formed verbs in μι; which in the present, imperfect, and second aorist, as it is called, have only a different form, by assuming μι with a long vowel preceding it, in the present active, which vowel is preserved in each person singular. This collection of irregular verbs seems to be formed from the verb ειμι, which in some dialects might be ημι. Indeed the imperfect ην, ης, η, seems to imply as much; but in this we cannot venture to be positive.

In the whole of this analysis of the formation of verbs, we have only laid down what appears to us most plausible. That metaphysical critics may discover inaccuracies in the preceding detail we make no doubt; but our candid readers will doubtless reflect, that no language was ever fabricated by philosophers, and that the elements of speech were hammered out by peasants, perhaps even by savages. Critics have created a philosophy of language, we admit, and have a thousand times discovered wonderful acuteness and ingenuity in the mechanism of words and sentences, where the original onomathetæ never apprehended any, and which possibly never existed except in their own imagination. If our more enlightened readers should find any thing in the preceding detail worthy their attention, so much the better; but if the contrary should happen, we presume they will adhere to the hackneyed system. We have all along neglected the dual number, because it regularly follows the type of the other numbers.

Before we take leave of this subject, however, we must use the freedom to subjoin an observation or two respecting the consequences of the practice of new-modelling the present, and of course the imperfect, tenses of verbs. First, after this arrangement had been made, the Greeks commonly retained all the other tenses exactly as they had stood connected with the primitive verb. This needs no example. Secondly, they often collected the tenses of verbs, the present and imperfect of which were now obsolete, in order to supply this defect. Thus we have φερω, ὀισιω, ἐνεγκα, ἠνοχα. Thirdly, they often formed the present and imperfect tenses without any other tenses annexed; and the poets in particular seem to have fabricated these two tenses at pleasure.

---

[1] We say generally, because in verbs ending in εω, the ε is sometimes retained, as τελεω-τελεσω, ἀρκεω-ἀρκεσω.

But if this procedure was convenient for the poets, it was certainly most incommodious with respect to the vulgar, as well as to all foreigners who had an inclination to learn the language. The vulgar, some ages after Homer and Hesiod, must have found it as difficult to understand their poems as our people do to comprehend those of Chaucer and Spenser. By this disposition, too, the etymology of verbs was almost entirely confounded. The present second future being, as has been observed, the ancient present, the attention of the curious etymologist was naturally diverted to the modern present, where it was utterly impossible to discover the radical word. A few examples will elucidate this point: τεινω, *to stretch, to extend*, old present τανω. Ταν is the radix, which at once appears to be a Persian word signifying *a large tract of country*. Hence *Mauritania*, the land of the Mauri, Aquitania, Britannia; and with the letter *s* prefixed, Hindu-stan, Chusi-stan, Turque-stan. The obsolete verb ὀπω, whence ὀπτομαι, is evidently derived from *op*, an Egyptian name of the moon; φαινω, second future φανῶ, *to show*, from the Egyptian word *phan* or *pan*, a name of the sun; τυπτω, future second τυπῶ, τυπ being obviously the offspring of תפ, *thaph*, a drum or timbrel, from beating or striking. In such etymological researches, the student must be careful to turn the Ionic η into the Doric α; because the Dorians came latest from the coast of Palestine, and consequently retained the largest share of the Phœnician dialect. Thus, γηθεω, *to rejoice*, turning η into α becomes γαθεω. This word, throwing away the termination, becomes *gath*, plainly signifying a *wine press*.[1] It is likewise to be observed, that the Æolians often changed α into υ, as συρξ instead of σαρξ, &c.

Greek infinitives used as nouns.

It is not our intention to enter at length into the arrangement and peculiar construction of the Greek language. There is one point, however, which we cannot well pass over in silence. As that tonguc is destitute of those words which the Latins call *gerunds*, to supply this defect they employ thc infinitive with the article prefixed: thus, Εἰς το εἰναι αὐτους φιλους, *in order to their being friends*; ἀπο του ἑλεσθαι αὐτους Βασιλεα, *from their having elected a king*; Ἐκ του ἀποφευγειν αὐτους ἐκ της πολεος, *from their flying out of the city*. In these phrases the infinitive is said to assume the nature of a substantive noun, agreeing with the article before it, exactly as if it were a noun of the neuter gender. Idioms of this kind occur in our own tongue; only with us the verb, instead of being expressed in the infinitive, is turned into the participle. According to this arrangement, the first of the preceding phrases, which, according to the Greek, would stand *toward to be friends*, in English is, *in order to their being friends*. This anomaly, then, if indeed it be such, is of no manner of consequence. The French, if we are not mistaken, would express it in the very same manner with the Greek, that is, *pour être amis*.

From treating of verbs, we should naturally proceed to the consideration of adverbs, which are so denominated, because they are generally the concomitants of verbs. Every thing relating to that part of speech, in the Greek tongue, may be seen in the Port Royal or any other Greek grammar. Instead, therefore, of dwelling upon this exhausted topic, we shall hazard a conjecture upon a point to which the critics in the Greek language, as far as we know, have not hitherto adverted.

Greek particles of oriental extraction.

The most elegant and most admired writers of Greece, and especially Homer, and after him Hesiod, abound with small particles, which appear to us pure expletives, created as it were to promote harmony, or fill up a blank without sense or signification. How these expletive particles should abound in that language beyond any other, is a matter which it does not seem easy to account for. It has been said by thc Zoiluses, that if you extract these nonentities from the poems of that bard, *qui solus meruit dici poeta*, a *magnum inane*, a mighty blank would remain behind. We would willingly do justice to that pigmy race of words, and at the same time vindicate the prince of poets from such a groundless imputation. Plato likewise, the prince of philosophers, has often been accused of too frequently employing these superfluous auxiliaries.

The particles in question were no doubt imported from the East. It would be ridiculous to imagine that any description of men, however enthusiastically fond they might be of harmonious numbers, would sit down on purpose to fabricate a race of monosyllables purely to eke out their verses, mere sounds without significance. In the first place, it may be observed, that there is a very strict connection amongst the particles of all cognate languages. To this we may add, that the not understanding the nature, relations, significations, and original import of those seemingly unimportant terms, has occasioned not only great uncertainty, but numberless errors in translating the ancient languages into the modern. The Greek language in particular loses a considerable part of its beauty, elegance, varicty, and energy, when these adverbial particlcs with which it is replete are not thoroughly comprehended. An exact translation of these small words, in appearance insignificant, would throw new light not only upon Homer and Hesiod, but even upon poets of a much posterior date. Particles, which are generally treated as mere expletives, would often be found energetically significant. It is, however, altogether impossible to succeed in this attempt without a competent skill in the Hebrew, Chaldaic, Arabian, Persian, and ancient Gothic languages.

We shall here take the liberty to mention a few of thosc particles which are most familiar to us, one or other of which occur in almost every line of Homer, and which wc believe are either not understood at all, or misunderstood. Such are Δα, δη, μεν, ηντοι, μαν, γε, ερι, αρα, ρα, γουν. Δα is nothing else but the Chaldaic particle δα, the parent of the English *the*. It likewise signifies *by turns*, or *in your turn*. Δη is the same word in the Ionic dialcct; μεν is a particle of the Hebrew affirmative אמן, *amen, fides, veritas*. Μαν is a kind of oath by the moon, called *mana*, almost over all the East, and hence *Dorice* μανα; γε, an oath by γεα, that is, *the earth*; αρα, another oath by the same elcment, probably from the oriental word of the same import; ρα is a fragment of αρα mentioned before; γουν, of γεα, *the earth*; ου or ων, an Egyptian name of the sun; and ως, *as*, a particle which pervades all the dialects of the Gothic language. In this manner we believe all these small words which occur so frequently in the Greek tongue, and which have hitherto been held as inexplicable, may easily bc rendered in significant terms; and werc this done, we believe they would add both beauty and energy to the clauses in which they stand. But this discussion must be left to more accomplished hellenists.

Prepositions.

We need not explain the nature of prepositions, because we are convinced that fcw people will take the trouble to peruse this disquisition who are not already acquainted with their import in language. The Greek prepositions, which are eighteen in number, need not be cnumerated here. Most of them might easily be shown to be particles, or fragments deduced from oriental or Gothic words. The usc of these words is to connect together terms in discourse, and to show the relation bctween them. In languages where, as in English, all these relations are expressed without any change on the termination of the nouns to which they are prefixed, the process is natural and easy. The whole is performed by juxtaposition. But in the Greek and Latin tongues, this effect is produced, partly by prefixing prepositions and partly by varying the terminations of nouns. Had the Greeks been able to intimate all these relations by varying the terminations, or had they multiplied their prepositions to such a number as would have enabled them to express these relations without the casual variations, as the northern languages have done; in either case their language would have been less embarrassing than it is in its present state. According to the present arrangement, both prepositions and the casual variations are used promiscuously to answer that purpose, a method which appears to be not altogether uniform. Though this plan might occasion little embarrassment to natives, it must, in our opinion, have proved somewhat perplexing to foreigners. In the case of the latter, the difficulty would be when to adopt the one and when the other expedient.

---

[1] Hence it came to signify rejoicing, from the mirth and revelry attending the treading of the vine-press.

Another inconvenience arises from the exceedingly small number of prepositions in that language, which indeed bear no adequate proportion to the great variety of relations they are appropriated to express. This deficiency obliged them frequently to employ the same preposition to denote different relations. For instance, ἐπι intimates, 1st, *upon*, as ἐπι του λιθου, *upon the stone*; and then it takes the genitive. 2d, It denotes *near upon*, as ἐπι τῳ λιθῳ; and then it governs the dative. 3d, The same preposition signifies *motion towards*, as ἐπεσεν ἐπι τον λιθον, *he fell upon the stone.* In these instances the same preposition intimates three different relations; and, which is still more embarrassing, each of these requires a different case. The difficulty in this instance is so considerable, that even the most accurate of the Greek writers themselves often either forget or neglect the true application. Many examples of this might be produced, did the limits assigned us admit of such illustrations. Every man who has carefully perused the Grecian authors will readily furnish himself with examples.

Again, some prepositions indicating different relations, are nevertheless prefixed to the same case. Thus, ἐξ signifies *from*, as, 'Εκ Διος ἀρχομεθα, *from Jupiter we begin*; ἀπ ἐμου βιου, *from my life*, or *my course of life*; προ των θυρων, *before the doors*; προ νικης ἐγκωμιον, *an encomium before the victory*; ἀντι ἀγαθων ἀποδιδοναι κακα, *to render evil for good*; ἀντι σου, *against you.* In these examples, and indeed every where, the propositions employed intimate different relations, and yet are prefixed to the same cases. Sometimes the same preposition would seem to assume two opposite significations, as appears from the preposition ἀντι just mentioned, which intimates both *for*, *instead of*, and *against* or *opposite to*.

What has been observed with respect to the prepositions above mentioned, the reader will readily enough apply to κατα, μετα, δια, περι. These incongruities certainly imply something irregular, and appear to intimate that those anomalies were so deeply incorporated with the constitution of the language, that the subsequent improvers found it impossible to correct them. Indeed, to prefix a preposition to a case already distinguished by the affixed termination, appears to us a superfluity at least, if not an absurdity; for certainly it would have been more natural to have said ἐκ Ζευς ἀρχομεθα, than ἐκ Διος ἀρχομεθα. Some very learned men, who have inquired into the origin of language, have been of opinion that prepositions formed the last invented species of words. If this opinion be well founded, we may suppose (and we think that such a supposition is not altogether improbable) that the casual terminations of the Greek language were first affixed to the radix, in the manner above exhibited; and that prepositions were afterwards fabricated and prefixed to the cases already in use.

The syntax or construction of the Greek language does not, according to our plan, come within the compass of our present inquiry. This the curious Greek student will easily acquire, by applying to the grammars composed for that purpose. We have already hazarded a few conjectures respecting the formation of the most important and most distinguished classes of words into which it has been divided by the most able grammarians, without, however, descending to the minutiæ of the language. But as prepositions are the chief materials with which its other words, especially verbs, are compounded, we shall briefly consider the order in which they probably advanced in this process of composition.

Complex ideas are compounded of a certain number or collection of simple ones. Of those complex notions, some contain a greater and others a smaller number of simple conceptions. In language, then, there are two ways of expressing such complex ideas; either by coining a word to express every simple idea separately, according to the order in which they stand in the mind; or by trying to combine two or more simple terms into one, and by this method to intimate one complex idea by one single word. The Arabians, notwithstanding all the boasted excellencies of their language, have never arrived at the art of compounding their words, in order to answer this noble purpose; and the sister dialects are but slenderly provided with this species of words. The Greeks, of all other nations, excepting perhaps those who spake the Sanscrit language, are unrivalled in the number, variety, propriety, elegance, energy, and expression of their compound terms. The Greeks, like the Arabians, in the earliest stages of their language, had only a collection of disjointed radical words, consisting of the jargons of the aboriginal Greeks, of the Pelasgi, Thracians, and others. How these words were arranged and constructed, we have no data remaining upon which we can found a critical investigation. We must therefore remain satisfied with such probable conjectures as the nature of the case, and the analogy of the language, seem to suggest.

The prepositions were originally placed before the nouns, the relations of which they pointed out. For example, let us take the ξυναπεθνησκετο τοις ἀλλοις, he died along with the rest, or he died out of hand along with the others. These words were arranged thus; ἀπεθνησκετο συν τοις ἀλλοις, and ἀποθνησκον συν τοις αλλοις. In this manner the parts of every compound word were placed separately, at least as much as other words which had no connection.

The firs compoun words in Greek.

The first compound words of the Greek language were those of the radical nouns with the article, and the radical part of the substantive or auxiliary verb. The success of this experiment encouraged them to attempt the same thing in other words. By this noble invention they found themselves able to express, in one word, with ease and significancy, what in other languages, and formerly in their own, required a tedious ambages or circumlocution. In process of time, as their language was gradually mellowed, they increased the number of their compounds, until, in this respect, the Greek infinitely excelled all its parent dialects. In this process they were careful to unite such letters as not only prevented asperity and difficulty of pronunciation, but even promoted harmony and elegance. But this was the labour of posterior ages.

The Greeks were entirely ignorant of the derivation or etymology of their language. For proof of this we need only consult Plato's *Cratylus*, Aristotle's *Rhetoric*, Demetrius Phalereus, Longinus, and others. But in deducing patronymics, abstracts, possessives, gentiles, diminutives, verbals, and the like, from radicals of every kind, they have shown the greatest art and dexterity. Examples of this occur almost in every page of every Greek author. But this extended no farther than their own language; every foreign language was an abomination to the Greeks.

Origina material of the Greek l guage.

The original materials of the Greek tongue were undoubtedly rough and discordant, as we have above described them. They had been collected from different quarters, they were the produce of different countries, and had been imported at very distant periods. It would therefore be an entertaining, if not an instructive, speculation, if it were possible to discover by what men and by what means, this wonderful fabric was founded, erected, and carried to perfection. The writers of Greece afford us no light on this matter. Foreigners were unacquainted with that originally insignificant canton. Every thing beyond Homer is buried in eternal oblivion. Orpheus is indeed reported to have composed poems; but these were soon obliterated by the hand of time. The verses which have been ascribed to that philosophical hero are none of his.[1] Linus wrote, in the Pelasgic dialect, the achievements of the first Bacchus; Thamyris the Thracian was also the author of verses; and Pronapides the master of Homer was a celebrated poet. But the works of these bards did not long survive; and it is a certain fact that the Greek tongue was highly polished even more early than the age in which these worthies flourished. Homer, no doubt, imitated their productions, and some are of opinion that he borrowed liberally from them. The Greeks knew no more of the original character of their language, than of the original character and complexion of their progenitors. They allowed, indeed, that their language was originally barbarous and uncouth; but by what means or by what persons it was polished, enriched, and finally arranged, remained to them an impenetrable secret.

I as carri to its u ost perfe on at a v early p d.

We have already demonstrated that the Ionim or aborigines of Greece were a race of barbarians; that consequently their language, or rather their jargon, was of the same contexture. The Pelasgians found both the people and their speech in this uncultivated state. These people arrived in Greece about the year before Christ 1760. It was then that the language of Greece began to be cultivated. Before the age of Homer the work seems to have been completed. Nothing of consequence was afterwards added to the original stock; on the contrary, not a few varieties were deducted from the Homeric treasure. The Pelasgians, as was said before, arrived in Greece 1760 B.C. Homer is thought to have been born in 1041 B.C.; consequently the cultivation of the Greek tongue was completed in a period of about seven hundred years. But upon the supposition that Orpheus, Linus, Thamyris, and others, wrote long before Homer, as they certainly did, that language had arrived nearly at the standard of perfection two centuries before; and by this computation the period of its progress towards its stationary point is reduced to five hundred years. But as the Pelasgians were a colony of foreigners, we ought to allow them one century at least to settle and incorporate with the natives, and to communicate their language, laws, manners, and habits, to the aborigines of the country. By this deduction we shall reduce the term of cultivation to less than four centuries.

During this period Greece was furiously agitated by tumults and insurrections. That country was divided into a number of independent states, which were perpetually engaged in quarrels and competitions. The profession of arms was absolutely necessary for the protection and preservation of the state; and the man of conduct and prowess was not only honoured as a demi-god, but his exploits were transmitted with eclat to posterity. The Greek tongue was then rough and unpolished; because, like the ancient Romans, the bravest men were more disposed to act than to speak. Every language will take its colour from the temper and character of those who employ it; and had it not been owing to one class of men, the Greek tongue would have continued to the era of Homer as rude as it had been a century after the arrival of the Pelasgians.

There has appeared amongst barbarous or half civilized people a description of men whose profession it has been to frequent the houses or palaces of the great, in order to celebrate their achievements, or those of their ancestors, in the sublimest strains of heroic poetry. Accordingly, we find that the Germans had their bards, the Gauls their fads, the Scandinavians their scalds, and the Irish their fileas, all retained for that very purpose. They lived with their chieftains or patrons, attended them to battle, were witnesses of their heroic deeds, animated them with martial strains, and celebrated their prowess, if they proved victorious; or, if they fell, raised the song of woe, and chanted the mournful dirge over their sepulchres. These bards were always both poets and musicians. Their persons were held sacred and inviolable. They attended public entertainments, and appeared in all national conventions. The chief of them were employed in the temples of the gods; and the less illustrious, like our minstrels of old, strolled about from place to place, and exercised their functions wherever they found encouragement.

Amongst the ancient Greeks there was a numerous tribe of men of the very same description who were at once poets and musicians, and whose office it was to celebrate the praises of the great, and to transmit their exploits to posterity with the most exaggerated encomiums. These poetical vagrants were styled Αοιδοι, or songsters. Some of them lived in the houses of great men; whilst others, less skilful or less fortunate, strolled about the country in the manner above described. The more illustrious of these Αοιδοι, who were retained in the temples of the gods, were certainly the first improvers of the language of the Greeks. Amongst the Hebrews we find that the first poetical compositions were hymns in honour of Jehovah; and amongst the pagans the same practice was established. In Greece, when all was confusion and devastation, the temples of the gods were held sacred and inviolable. There the Αοιδοι improved their talents, and formed religious anthems upon those very models which their progenitors had chanted in the East.

Distinction between the language of gods and of men.

The language of the Greeks being yet rugged and unmellowed, their first care was to render it softer and more flexible. They enriched it with terms suited to the offices of religion; and these, we imagine, were chiefly imported from the East. Homer every where mentions a distinction between the language of gods and men. The language of gods imports the oriental terms retained in the temples, and used in treating of the ceremonies of religion; the language of men intimates the ordinary civil dialect which sprung from the mixed dialects of the country. The priests no doubt concurred in promoting the noble and important purpose. From this source the strolling Αοιδοι drew the rudiments of their art; and from these songsters, again, the vulgar deduced the elements of a polished style.

To the Αοιδοι of the superior order we would venture to ascribe those changes mentioned in the preceding part of this inquiry, by which the Greek tongue acquired that variety and flexibility, from which it has in a great measure derived that ease, beauty, and versatility, by which it now surpasses most other languages. The diversity of its terminations furnishes a most charming variety, whilst at the same time the sense is communicated to the reader or hearer by the relation between them. By this economy the poet and the orator are left at liberty to arrange their phrases in that order which may be most soothing to the ear, and best adapted to make a lasting impression on the mind.

Few colonies have emigrated from any civilized country without a detachment of priests in their train. The supreme powers, whoever they were, have always been worshipped with music and dancing. The Hebrews, Phœnicians, and Egyptians, delighted in these musical and jocund festivals. The priests who attended the Ionians, Dorians, Æolians, Thebans, Athenians, &c. from the East, introduced into Greece that exquisite taste, and those delicate musical feelings, which distinguish the Greeks from all the neighbouring nations. Hence the numerous progeny of onomatapœas, by which the Greek language is invested with the power of expressing almost every passion of the human soul, in such terms as oblige it to feel and actually to assimilate to the passion it would excite. Numberless instances of this occur in every page of Homer, Hesiod, Pindar, Sophocles, Euripides, and even of Aristophanes; but to quote instances would be to insult the student of Greek.

---

[1] Pausanias, lib. i. cap. 22.

Every body knows that the practice of writing in verse was antecedent to the epoch of prosaic composition. Here, then, the Αοιδοι and the ministers of religion chiefly displayed their skill and discernment. By a judicious mixture of short and long syllables, by a junction of consonants which naturally slide into each other, and by a careful attention to the rhythm, or harmony resulting from the combination of the syllables of the whole line, they completed the metrical tone of the verse, guided by that delicacy of musical feeling of which they were possessed before rules of prosody were known amongst men.

Much liberty was certainly used in transposing letters, in varying terminations, and also in annexing prefixes and affixes, both to nouns and other kinds of words where such adjuncts were possible; and upon this occasion we think it probable, that those particles of which we have already spoken were inserted like filling stones thrust in to stop the gaps or chinks of a building. Verses were then clumsy and irregular, as the quantity of vowels was not duly ascertained, and the collision of heterogeneous consonants not always avoided. Probably these primitive verses differed as widely from the finished strains of Homer and his successors, as those of Chaucer and Spencer do from the smooth and polished lines of Dryden and Pope.

Earliest poets of Greece.

The poetical compositions of the earliest Greeks were not, we think, in the hexameter style. As they were chiefly calculated for religious services, we imagine they resembled the Hebrew iambics preserved in the song of Aaron and Miriam, Deborah and Barak, Psalms, Proverbs, &c. which were indeed calculated for the same purpose. Archilochus perhaps imitated these, though the model upon which he formed his iambics was not generally known. The later dramatic poets appear to have copied from the same archetypes. Hexameters, it is probable, were invented by Orpheus, Linus, Thamyris, Musæus, and their contemporaries. The first of these travelled into Egypt, where he might learn the hexameter measure from the people of that country, who used to bewail Maneros and Osiris in elegiac strains. This species of metre was first consecrated to theology, and the most profound sciences of moral and natural philosophy; but at length it was employed to celebrate the exploits of kings and heroes.

> Res gestas regumque, ducumque, et fortia bella,
> Quo scribi possent numero monstravit Homerus.

Orpheus, &c.

We have hazarded a conjecture above, importing that the earliest poetical compositions of the Greeks were consecrated to the service of the gods. We shall now produce a few facts, which will furnish at least a presumptive evidence of the probability of this conjecture.

Orpheus commences his poem with ancient chaos, its transformations and changes, and pursues it through its various revolutions. He then goes on to describe the offspring of Saturn, that is time, the æther, love, and light. In short, his whole poem is said to have been an oriental allegory, calculated to inspire mankind with the fear of the gods, and to deter them from murder, and rapine, and unnatural lusts. Musæus was the favourite scholar of Orpheus, nay perhaps his son. He composed prophecies and hymns, and wrote sacred instructions, which he addressed to his own son. He prescribed atonements and lustrations; but his great work was a Theogony, or History of the Creation. Melampus brought from Egypt into Greece the mysteries of Proserpine. He wrote the whole history of the disasters of the gods. This seer is mentioned by Homer himself. Olen came from Lycia, and composed the first hymn which was sung in Delos at their solemnities; he probably emigrated from Patara a city of Lycia, where Apollo had a celebrated temple and oracle. The Hyperborean damsels used to visit Delos, where they chaunted sacred hymns in honour of the Delian god. To these we may add the great Homer himself, if indeed the hymns commonly annexed to the Odyssey are his composition. Hesiod's Theogony is too well known to require any description. From these instances it appears, that the origin of the poetry of Greece is to be found in the temples; and that there, its measure, numbers, rhythm, and other appendages, were originally fabricated.

Different dialects, with thei origin.

The Grecian poets, however, enjoyed another advantage which that class of writers have seldom possessed, and which arose from the different dialects into which their language was divided. All these dialects were adopted indifferently by the prince of poets; a circumstance which enabled him to take advantage of any word from any dialect, provided it suited his purpose. This, at the same time that it rendered his versification easy, diffused an agreeable variety over his composition. He even accommodated words from Macedonia, Epirus, and Illyricum, to the purposes of his versification. Besides, the laws of quantity were not then clearly ascertained; and this circumstance afforded him another convenience. Succeeding poets did not enjoy these advantages, and consequently have been more circumscribed both in their diction and their numbers.

The Greek language, as is generally known, was divided into many different dialects. Every sept, or petty canton, had some peculiar forms of speech which distinguished it from the others. There were, however, four different dialetical variations which predominated over all the others; namely, the Attic, Ionic, Æolic, and Doric. These four dialetical distinctions originated from the different countries in the East whence the tribes respectively emigrated. The Attics consisted, first, of the barbarous aborigines; secondly, of an adventitious colony of Egyptian Saïtes; thirdly, a branch of Ionians from the coast of Palestine. These last formed the old Ionian dialect, from which sprung the Attic and the modern Ionic. The Æolians emigrated from a different quarter of the same coast, the inhabitants of which were a remnant of the old Canaanites, and consequently different in dialect from the two first-mentioned colonies. The Dorians sprang from an unpolished race of purple-fishers on the same coast, and consequently spoke a dialect coarser and more rustic than any of the rest. These four nations emigrated from different regions; a circumstance which, in our opinion, laid the foundation of the different dialects by which they were afterwards distinguished.

It is impossible in this short sketch to exhibit an exact view of the distinguishing features of each dialect. Such an analysis would carry us far beyond the limits assigned to the present article. For entire satisfaction on this head, we must refer the Grecian student to Mattaire's *Grecæ Linguæ Dialecti*, where he will find every thing necessary to qualify him for understanding that subject; and, in the meantime, we shall content ourselves with the few following observations.

The Athenians being an active, brisk, volatile race, delighted in contractions. Their style was most exquisitely polished. The most celebrated authors who wrote in that dialect were, Plato, Thucydides, Xenophon, Demosthenes, and the other orators; Æschylus, Euripides, Sophocles, Aristophanes, Menander, Diphilus, with the other comic and tragic poets. That dialect was either ancient or modern. The ancient Attic was the same with the Ionic.

The Ionic, as we have already said, was the ancient Attic; but when that nation emigrated from Attica and settled on the coast of Asia Minor, they mingled with the Carians and Pelasgians, and of course adopted a number of their terms. They were an indolent, luxurious, and dissolute people; and hence their style was easy and flowing, but verbose, redundant, and without nerve or vigour. This however, is the leading style in Homer; and after him a prodigious number of writers on every subject employed the same dialect, such as Herodotus of Halicarnassus the celebrated historian; Ctesias of Cnidus the historian of Persia and India; Hecatæus of Miletus; Megasthenes the historian, who lived under Seleucus Nicator; Hippocrates the celebrated physician of Coos; Hellanicus the historian often mentioned with honour by Polybius; Anacreon of Teia, Alcæus, Sappho of Lesbos, excellent poets; Pherecydes Syrus the philosopher, and a multitude of other persons of the same profession, whom it would be superfluous to mention on the present occasion.

The Æolic and the Doric were originally cognate dialects. When the Dorians invaded Peloponnesus, and settled in that peninsula, they incorporated with the Æolians, and their two dialects, blended into one, produced the new Doric. The original Dorians inhabited a rugged mountainous region about Ossa and Pindus, and spoke a rough unpolished language similar to the soil which they inhabited. Andreas Schottus, in his Observations on Poetry (lib. ii. cap. 50) proves from an old manuscript of Theocritus, that there were two dialects of the Doric tongue, the one ancient and the other modern; that this poet employed Ionic and the modern Doric; that the old Doric dialect was rough and cumbrous; but that Theocritus adopted the new as being softer and more mellow. A prodigious number of poets and philosophers wrote in this dialect, such as Epicharmus the poet; Ibycus the poet of Rhegium; Corinna the poetess of Thespis, or Thebes, or Corinth, who bore away the prize of poetry from Pindar; Erynna a poetess of Lesbos; Moschus the poet of Syracuse; Sappho the poetess of Mitylene; Pindar of Thebes, the prince of all lyric poets; Archimedes of Syracuse, the renowned mathematician, and almost all the Pythagorean philosophers. Few historians wrote in that dialect; or if they did, their works have not fallen into our hands. Most of the hymns chanted in temples of the gods were composed in Doric; a circumstance which evinces the antiquity of that dialect, and which, at the same time, proves its affinity to the oriental standard.

T parti- al of the G ks to th own to he.

After the Greek tongue had been thoroughly polished by the steps which we have endeavoured to trace in the preceding pages, conscious of the superior excellency of their own language, the Greeks, in the pride of their hearts, stigmatised every nation which did not employ their language with the contemptuous title of *barbarians*. Such was the delicacy of their pampered ears, that they could not endure the untutored voice of the people whom they called βαρβαροφωνοι. This extreme delicacy produced three very pernicious effects. First, it induced them to metamorphose and sometimes even to mangle, foreign names, in order to reduce their sound to the Grecian standard; and, secondly, it prevented their learning the languages of the East, the knowledge of which would have opened to them an avenue to the records, annals, antiquities, laws, and customs, of the people of those countries, in comparison of whom the Greeks themselves were of yesterday, and knew nothing. By this unlucky bias, not only they, but even we who derive all the little knowledge of antiquity which we possess through the channel of their writings, have suffered an irreparable injury. By their transformation of oriental names they have in a manner stopped the channel of communication between the histories of Europe and Asia. This appears evident from the fragments of Ctesias's Persian history, from Herodotus, Xenophon, and all the other Grecian writers who have occasion to mention the intercourse between the Greeks and the Persians. The same absurd prejudice deprived them of all knowledge of the etymology of their own language, without which it was impossible for them to understand thoroughly its words, phraseology, and idioms. We have mentioned above the Cratylus of Plato. In that dialogue, the divine philosopher endeavours to investigate the etymology of only a few Greek words; but his deductions are absolutely childish, and little superior to the random conjectures of a school-boy. Varro, the most learned of all the Romans, has not been more successful. Both stumbled on the very threshold of that useful science; and a scholar of very moderate proficiency in our days knows more of the origin of these two noble languages, than the greatest adepts amongst the natives did in theirs. By prefixes, affixes, transpositions of letters, and new conjunctions of vowels and consonants for the sake of the music and rhythm, they have so disguised their words, that it is now almost impossible to develope their original. As a proof of this, we remember to have seen in the hands of a private person a manuscript, in which the first twelve verses of the Iliad are carefully analysed; and it appears to our satisfaction, that almost every word may be, and actually is traced back to a Hebrew, Phœnician, Chaldean, or Ægyptian original. And we are convinced that the same process will hold good in the like number of verses taken from any of the most celebrated poets of Greece. This investigation was chiefly conducted by reducing the words to their original invariable state, which was done by stripping them of prefixes, affixes, and other adventitious elements.

Beauty of the Greek language.

These imperfections, however, are counterbalanced by numberless excellencies; and we are certainly much more indebted to that incomparable people for the information they have transmitted to us through the medium of their writings, than injured by them in not conveying to themselves and to us more authentic and more ample communications of ancient events and occurrences. Without fatiguing our readers with superfluous ecomiums on a language which has long ago been extolled perhaps to an extravagant degree by the labours of men of the greatest capacity and the most refined taste, we shall now proceed to make a few observations on *spirits* and *accents*, which, being rather appendages than essentials of the language, we have on purpose reserved for the last place.

The spirits

Every word in the Greek language beginning with a vowel is marked with a spirit or breathing; and this aspiration is double, namely, *lenis et asper*, the gentle, and rough or aspirated. The gentle accent, though always marked, is not now pronounced, though in the earliest periods of the language it was undoubtedly enounced, although very softly. Both these aspirations were imported from the East. They were actually the Hebrew ה *he* and ח *heth*. The former denoted the *spiritus lenis*, the latter the *spiritus asper*. The Hebrew prefixed *ha* or *he* to words beginning with a vowel, and of course the Greeks followed their example. This people appears to have delighted in aspirates; and consequently the letter ς is, some think, rather too often affixed to the terminations of their words. Every word beginning with ρ had the aspirate joined to ρ, probably with the design of rendering the aspiration still rougher.

The accents.

The Greek accents are three in number; the acute, the grave, and the circumflex. The acute raises and sharpens the voice; the grave depresses and flattens it; the circumflex first raises and sharpens the voice, and then depresses and flattens it. It is obviously composed of the other two. The learned author of the *Origin and Progress of Language* has taken much pains to prove that these accents were actually musical notes, invented and accommodated to raise, depress, and suspend the voice, according to a scale of musical proportions. It is scarcely possible, we think, for a modern Greek scholar to comprehend distinctly the ancient theory of accents. These the native Greeks learned from their infancy, and that with such accuracy, that even the vulgar amongst the Athenians would have hissed an actor off the stage or an orator off the pulpitum, on account of a few mistakes in the enunciation of these notes.

The elevations, depressions, and suspensions of the voice upon certain syllables, must have made their language sound in the ears of foreigners somewhat like recitative, or something nearly resembling *cant*. But the little variety of these syllabic tones, and the voice not resting upon them, but running them on without interruption, sufficiently distinguished them from music or cant. Be that as it may, we think it highly probable, that the wonderful effects produced by the harangues of the orators of Greece on the enraptured minds of their hearers, were in a great measure owing to the artificial musical tones by which their syllables were so happily diversified. To this purpose we shall take the liberty to transcribe a passage from Dionysius of Halicarnassus *De Structura Orationis*, which we find translated by the author of the *Origin and Progress of Language*, (vol. ii. part ii. chap. 7, p. 381.) "Rhetorical composition is a kind of music, differing only from song or instrumental music, in the degree, not in the kind; for in this composition the words have melody, rythm, variety, or change, and what is proper or becoming; so that in it, as well as in music, the ear is delighted with the melody, moved by the rythm, is fond of variety, and desires with all these what is proper and suitable. The difference, therefore, is only one of greater and less."

With respect to accents, it may be observed that only one syllable of a word is capable of receiving the acute accent, however many there be in the word. It was thought that the raising the tone upon more than one syllable of the word, would have made the pronunciation too various and complicated, and too like chanting. The *grave accent* always takes place when the acute is wanting. It accords with the level of the discourse; whereas the acute raises the voice above it. The *circumflex accent* being composed of the other two is always placed over a long syllable, because it is impossible first to elevate the voice and then to depress it upon a short one. Indeed amongst the Greeks a long syllable was pronounced like two short ones; and we apprehend it was sometimes written so, especially in later times. It is perfectly obvious from two learned Greek authors, Dionysius of Halicarnassus, and Aristoxenus, that the Greek accents were actually musical notes; and that these tones did not consist of loud and low, or simply elevating and depressing the voice, but that they were uttered in such a manner as to produce a melodious rythm in discourse. In a word, the acute accent might be placed upon any syllable before the antepenult, and it rose to a fifth in the diatonic scale of music, whilst the grave fell to the third below it. The circumflex was regulated according to the measure of both, the acute always preceding. The grave accent is never marked except over the last syllable. When no accent is marked, there the grave always takes place. Some words are called *enclitics*. These have no accent expressed, but throw it back upon the preceding word. The circumflex, when the last syllable is short, is often found over the penult, but never over any other syllable except the last or the last but one.

The ancient Greeks had no accentual marks. These modifications of voice they learned by practice from their infancy; and we are assured by good authority, that in pronunciation they observe them to this day. The accentual marks are said to have been invented by a celebrated grammarian, Aristophanes of Byzantium, keeper of the Alexandrian library under Ptolemy Philopater, and by Epiphanes, who is also supposed to have invented punctuation. Accentual marks, however, were not in common use till about the seventh century; at which time they are found in manuscripts.[1]

Such, in general, are the observations which we conceived that the nature of our design obliged us to make on the origin and progress of the Greek language. Some of our more learned readers may perhaps blame us for not interspersing the whole disquisition with quotations from the most celebrated writers in the language which has been the object of our researches; and we are well aware that this is the general practice in such cases. The books were before us, and we might have transcribed from them more quotations than the nature of an article of this kind would permit. In the first part there were no books in that language to quote from, because the Greeks knew nothing of their own origin, nor of that of their language, and consequently have recorded nothing but dreams and fictions in reference to that subject. Even when we had made considerable progress in our inquiry, the nature of the plan we had adopted excluded in a great measure the use of quotations. When we drew near the conclusion, we imagined that our learned readers would naturally have recourse to the passages alluded to without our information, and that the unlearned would not trouble themselves about the matter. The Greek student who intends to penetrate into the depths of this excellent language, will endeavour to be thoroughly acquainted with the books mentioned below.[2]

Vast extent of t Greek La guage.

We shall now subjoin a brief account of the vast extent of the Greek language even before the Macedonian empire was erected; at which period it became in a manner general, much more so, indeed, than ever the Latin language could accomplish notwithstanding the vast extent of the Roman empire.

Greece, originally Hellas, was a region of but small extent, and yet sent out numerous colonies into different parts of the world. These colonies carried along with them their native language, and industriously diffused it wherever they formed a settlement. The Ionians, Æolians, and Dorians, possessed themselves of all the west, and north-west coast of the Lesser Asia and the adjacent islands; and there even the barbarians learned the polished language of Greece. The Greek colonies extended themselves along the southern coast of the Euxine Sea as far as Sinope, now Trebizond, and all the way from the western coast of Asia Minor; and though many cities of barbarians lay between, the Greek tongue was understood and generally spoken by people of rank and fashion. There were also Greek cities on the northern coast of the Euxine Sea to the very eastern point, and perhaps beyond even those limits; likewise in the Taurica Chersonesus, or Crim Tartary; and even to the mouth of the Danube, the straits of Caffa, &c. In the neighbourhood of all these colonies, the Greek language was carefully propagated amongst the barbarians, who carried on commerce with the Greeks.

A great part of the south of Italy was planted with Greek cities upon both coasts, so that the country was denominated Magna Græcia; and here the Greek tongue universally prevailed. In Sicily it was in a manner vernacular. The Io-

[1] If the curious reader should wish to enter more deeply into the theory of accents, we must refer him to *Origin of Language*, vol. ii. lib. 2. passim; and to Mr. Foster's *Essay on the different Nature of Accent and Quantity*.

[2] Aristotle's *Rhetoric and Poetics*, and his book *De Interpretatione*, especially with Ammonius's *Commentary*. Ammonius was a native of Alexandria, and by far the most acute of all the ancient grammarians. Dionysius of Halicarnassus *De Structura Orationis*, where, amidst abundance of curious and interesting observations, will be found the true pronunciation of the Greek letters. Demetrius Phalereus *De Elocutione*; a short essay indeed, but replete with instruction concerning the proper arrangement of words and members in sentences. Longinus, the prince of critics, whose remains are above commendation. Theodorus Gaza and the other refugees from Constantinople, who found an hospitable reception from the munificent family of the Medici, and whose learned labours in their native language once more revived learning and good taste in Europe. These, with some other critics of less celebrity, but equal utility, will unfold all the treasures of Grecian erudition, without however disclosing the source from which they flowed. To the above authors may be added a few celebrated moderns, such as M. Fourmont the Elder, M. Gebelin, Abbé Pezron, Salmasius, and especially the learned and industrious Lord Monboddo.

eek
uage.

nians had sent a colony into Egypt in the reign of Psammetichus; and a Greek settlement had been formed in Cyrenia many ages before. The Phocians had built Massilia or Marseilles as early as the reign of Cyrus the Great, where some remains of the Greek language are still to be discovered. Cæsar tells us, that in the camp of Helvetii registers were found in Greek letters. Perhaps no language ever had so extensive a diffusion, where it was not propagated by the law of conquest.

spo-
pre-

The Greek tongue, at this day, is confined within very narrow limits. It is spoken in Greece itself, except in Epirus or Albania, and the western parts of Macedonia. It is likewise spoken in the Grecian and Asiatic islands, in Candia or Crete, in some parts of the coast of Asia Minor, and in Cyprus; but in all these regions, it is much corrupted and degenerated. As a specimen, we shall insert a modern Greek song, and the advertisement of a quack medicine, which, with other plunder, was brought by the Russians from Chocsim or Chotzim in 1772.

ΜΙ δυσικίαις πολεμῶ μί βάσανα ὡς τὸ λεμό
  Εἶμαι καὶ κεντινεύω, καὶ νὰ χαθω κοντεύω
Στὸ πέλαγος των συμφυρῶν με ἐπίκινδυνον καιρὸν
  Μ' ανέμȣς ὀλάθριȣς σφοδρȣς και εναντιȣς.
Με κύματα πολλῶν καὶ μῶν τȣφανὶ άναϛενασμῶν.
  Θαλασσα φȣοκομένη, πόλλα ἀγριομένη,
῎Οπȣ ἀφρίζι καί φησὰ γε σαγανάκια περισσά
  Σύνεφα σκοτισμένα καὶ κατασυγχισμένα,
Και νὰ φανῆ μιὰ σωτηρία, νὰ ιδȣν τά μάτιά μȣϛεριὰ.
  Γλίχα νερά νὰ εὔρω, κάσχα καί δεν ἠξεύρῶ.
Ν' ἀραξω και δεν ἠμπορῶ γιατι λιμένα δεν θορῶ.
  Μ' ἀτελπισίαν θρέχω οτα ἄρμενα πȣ ἐχω.
Πȣ μὲ αὐτὰ κἀν νὰ πνυγῶ ἤ σελαμέτινα εὐγῶ,
  Καὶ τȣτα ἄν βαϛαξȣν, ἐμπορȣν νὰ μὲ φυλαξȣν.

  With dire misfortunes, pains, and woes,
O'erwhelm'd, ingulph'd, I struggling fight;
  O'er my frail bark proud billows close,
To plunge her deep in lasting night.
  Rough seas of ills incessant roar,
Fierce winds adverse, with howling blast,
  Heave surge on surge. Ah, far from shore
My found'ring skiff shall sink at last.
  Involv'd in low'ring darksome clouds,
'Mid sultry fogs, I pant for breath;
  Huge foaming billows rend my shrouds,
While yawning gulfs extend beneath.
  From bursting clouds loud thunders roll,
And deaf'ning peals terrific spread;
  Red lightnings dart from pole to pole,
And burst o'er my devoted head.
  When shall the friendly dawning rays
Guide me to pleasures once possest;
  And breezy gales, o'er peaceful seas,
Waft to some port of endless rest?
  In dark despair, with tempests tost,
I veer my sail from side to side.
  Conduct me, Heav'n! to yon fair coast,
  Or plunge me in the 'whelming tide.

ΒΑΛΣΑΜΟΝ ΤΗΣ ῾ΙΕΡΟΥΣΑΛΗΜ, ΑΠΟ ΤΑΙΣ, ΚΑΙ ΝΟΥΡΙΑΙΣ, ΚΑΙ ΠΑΛΕΑΙΣ ΡΕΤΖΕΤΑΙΣ.

ΤΟΥΤΟ τὸ μπαλσαμον ὠφελεῖ εις τὸ ἀδυνατόν ϛομαχι, καὶ βοηθεῖ τὴν χονευσιν δυναμώνει τὴν καρδίαν. συκώνει ὄλας τὰς ἐμφράξεις τῆς κοιλιας ωφελεῖ εἰς τὴν ϛενωσιν καὶ βῆχα παλαιὸν. ῾Ιατρέυεί τὰς ἐσωτερικὰς πληγὰς τȣ ϛήθȣς, καὶ τȣ πνεύμονος ἤγουν πλεμονίȣ. κινεῖ τα καταμήνια τῶν γυναικῶν. ᾿Εις τὰς ἐξωτερικὰς πληγὰς πρέπει νὰ βάζεται μὲ τὸ ξανθὸ πόσον ἐις παλαιὰς. Οσον καὶ ἐιονεας, καθὼς εἶναι ἡ οπαθιᾶις, καὶ μαχαιριαῖς, καὶ ἀλλα κοψίματα ἰατρευει κάθελογῆς Φιϛολα, καὶ ὀλας τὰς βρομερὰς πληγὰς ὁπȣ ἔφθασαν ἐις τὸ κὄκαλον θαυμάσιως, ὠφελεῖ εἰς τὰ ἀυτία ὁπȣ τρέχουν ἔμπυον νά ϛαζεται δὺο ἢ τρεῖς κόμπȣς ἤχουν ϛαλαγματίας μεϐαμπάκι βρεμμένον εἰς ἀυτὸ, βάνεται εἰς τὰς πληγωμενας δοντοκοιλιαῖς καὶ θέλουν ʽατρευθῆ. καὶ ἀκόμι δυναμώνει τὰ ὀδόντια ὁπȣ κινοῦν ται δε θελουν νὰ πέσουν· βοηθᾶ καὶ ἀπὸ τὴν πανȣκλαν.

῾Η δόσις ἐσωτερικῶς ἂς εἶναι δεκα ἢ καὶ δώδεκα κόμπȣς εἰς ὀλίγον κρασὶ, ἢ καὶ νερον, τὸ κάθε ταχυ καὶ βράδυ. ἂς τὸ μεταχειρίζεται, κὰι εἶνα θαυμάσιον μὲτὴν δοκιμὴν βεϐαιωμενον.

᾿Αληθὲς βάλσαμον τȣ Βασιλειȣ.

Instead of giving a literal and bald translation of this advertisement, which runs exactly in the style of other quack bills, it may be sufficient to observe, that the medicine recommended is said, when taken inwardly, to raise the spirits, remove costiveness and inveterate coughs; to cure pains of the breast and stomach-aches; to assist respiration, and remove certain female obstructions. When applied externally, it cures wounds and sores, whether old or fresh, removes ringing of the ears, fastens the teeth when loose, and strengthens the gums. All this, and much more, it is said to do in a wonderful manner; and is declared to be the true royal balsam of Jerusalem, and an universal specific.

It is indeed next to a miracle that so many monuments of Grecian literature are still to be found amongst men. Notwithstanding the burning of the famous library of Alexandria, and the almost numberless wars, massacres, and devastations, which have from time to time in a manner desolated those countries where the Greek once flourished; we are told that there still remain about three thousand books written in that language.

Stages of the Greek language.

We shall now conclude this section with a brief detail of the most distinguished stages and variations through which this noble tongue passed from the age of Homer till the taking of Constantinople, in the year 1453, a period of more than two thousand years.

Homer gave the Greek poetry its colour and consistency, and enriched, as well as harmonized, the language. From the coincidence of epithets and cadence in Homer and Hesiod, it appears that the Greek heroic verse was formed spontaneously, by the old Αοιδοι, a sort of *improvisatori;* and that Homer and his early followers adopted their versification. The Iliad and Odyssey have much of the air of extempore compositions; an epithet is never wanting to fill up a verse; and a set of expressions are mechanically annexed to such ideas as were of frequent recurrence. Hence that copiousness and profusion of words in the old Greek bard, which forms such a contrast to the condensed and laboured composition of Virgil.

The Greek prose was of a more difficult structure; and it may be distributed into different styles or degrees of purity. Of the prose authors now extant, the first and best style is that of Herodotus in the natural, and of Plato in the florid or mixed kind, of Xenophon in the pure and simple, of Thucydides and Demosthenes in the austere style. Nothing, perhaps, is so conducive to form a good taste in composition as the study of these writers.

The style of Polybius forms a new epoch in the history of the Greek language. It was the idiotic or popular manner of expression, especially amongst military men, in his time, that is, about the 150th Olympiad. It became the model of succeeding writers, by introducing a simple unstudied expression, and by emancipating them from the anxious labour of the old Greeks respecting the cadence and choice of words. The style of the New Testament, being plain and popular, frequently resembles that of Polybius, as has been fully shown by Raphelius, and by Kirchmaier.[1]

---

[1] *De Parallelismo Novi Testamenti et Polybii*, 1725.

Before this historian, the Alexandrian Jews had formed a new or Hellenistic style, resulting from the expression of oriental ideas and idioms in Greek words, after that language had lost of its purity, in proportion as it gained in general use, by the conquests of Alexander. The Hellenistic is the language of the Septuagint, the Apocrypha, the New Testament, and partly of Philo and Josephus. This mixture in the style of the evangelists and apostles, is one credential of the authenticity of the best of all books, a book which could not have been written except by Jewish authors in the first century.[1] Critics lose their labour in attempting to adjust the Scripture-Greek to the standard of Atticism.

The diction of the Greek historians, and geographers of the Augustan age, is formed on that of Polybius, but improved and modernized, like the English of the present age, as compared with that of Clarendon or Bacon. More perspicuous than refined, it was well suited to such compilations as were then written by men of letters, such as Dionysius, Diodorus, and Strabo, without much experience or any eminent rank in public life.

The ecclesiastical style was cultivated in the Christian schools of Alexandria, Antioch, and Constantinople; it was rank and luxuriant, full of oriental idioms, and formed in a great measure on the Septuagint version. Such for instance, is the style of Eusebius. After him, the best Christian writers polished their compositions in the schools of rhetoric under the later sophists. Hence the popular and flowing purity of St. Chrysostom, who has more good sense than Plato, and perhaps as many good words.

On the Greek of the Byzantine empire, there is an excellent dissertation by Ducange, *de Causis corruptæ Græcitatis*, prefixed to his glossary, together with Portius's Grammar of the modern Greek. This last stage of the Greek language presents a miserable picture of Turkish barbarism; and, what is most surprising, there is no city of Greece where the language is more different from the ancient than at Athens; the reason of which seems to be, that that city has long been inhabited by a mixed multitude of different nations.

In a word, the Greeks have left the most durable monuments of human wisdom, fortitude, magnificence, and ingenuity, in their improvement of every art and science, and in the finest writings upon every subject necessary, profitable, elegant, or entertaining. They have furnished the brightest examples of every virtue and accomplishment, natural or acquired, political, moral, or military. They excelled in mathematics and philosophy; in all the forms of government, in architecture, navigation, commerce, war; as orators, poets, and historians, they stand yet unrivalled, and are likely to remain so for ever; nor are they less to be admired for the exercises and amusements they invented, and brought to perfection, in the institution of their public games, their theatres, and sports.

No perfect translation of any Greek author.

Let us further observe, that in vain will our readers look for these admired excellencies in any of the best translations from the Greek; they may indeed communicate some knowledge of what the originals contain; they may present the reader with propositions, characters, and events; but allowing them to be more faithful and more accurate than they really are, or can well be, still they are no better than copies, in which the spirit and lustre of the originals are almost totally lost. The mind may be instructed, but will not be enchanted; the picture may bear some faint resemblance, and if painted by a masterly hand may give pleasure; but who would be satisfied with the canvass, when he may possess the real object? who would prefer a piece of coloured glass to a diamond? It is not possible to preserve the beauties of the original in a translation. The powers of the Greek vastly exceed those of any other tongue. Whatever the Greeks describe is always felt, and almost seen; motion and music are in every tone, enthusiasm and enchantment possess the mind.

> Graiis ingenium, Graiis dedit ore rotundo,
> Musa loqui.

SECT. VIII. OF THE LATIN LANGUAGE.

Origin o the Ro- mans, an of their languag

This language, like every other spoken by barbarians, was in its beginning rough and uncultivated. What people the Romans were, is a point as to which antiquarians are not yet agreed. In their own opinion they were sprung from the Trojans;[2] Dionysius of Halicarnassus derives them from the Greeks;[3] and Plutarch informs us[4] that some people imagined they were sprung from the Pelasgians. The fact is, they were a mixture of people collected out of Latium and the adjacent parts, whom a variety of accidents had induced or compelled to establish themselves in that mountainous region, in order to secure their own property, and plunder that of their neighbours. They were in all probability composed of Arcadians, Sabines, Latins, Hetruscans, Umbrians, Oscans, Pelasgians, and others; and if so, their language must have been a mixture of the different dialects peculiar to all these discordant tribes.

The Latin language ought then to be a commingled mass of the Arcadian, that is, the Æolian Greek,[5] the Pelasgic, Hetruscan, and Celtic dialects. But these jarring elements, like the people to whom they respectively belonged, gradually incorporated, and produced what was afterwards called the Latin tongue.

The Arcadians were a Pelasgian tribe,[6] and consequently spoke a dialect of that ancient Greek produced by the coalition of this tribe with the savage aborigines of Greece. This dialect was the ground-work of the Latin. Every scholar allows, that the Æolian Greek, which was strongly tinctured with the Pelasgic, constituted the model upon which the Latin language was formed. From this deduction it appears, that the Latin tongue is much more ancient than the modern Greek; and of course we may add, that the Greek, as it stood before it was thoroughly polished, bore a very near resemblance to that language. Hence it may be concluded, that the knowledge of the Latin language is necessary in order to understand the Greek. Let us not then expect to find the real ingredients of the Greek tongue in the academic groves of Athens, or in Smyrna, or in Rhodope, or in Hæmus; but let us seek for them on the banks of the Tiber, and on the fields of Laurentum.

A very considerable part of the Latin tongue was derived from the Hetruscan. That people were the masters of the Romans in every thing sacred. From them they learned the ceremonies of religion, the method of arranging games and public festivals, the art of divination, the interpretation of omens, the method of lustrations, expiations, &c. It would, we believe, be easy to prove, that the Pelasgians[7] and Hetruscans[8] were the same race of people; and if this was the case, their languages must have differed in dialect only.

The Umbrian or the Celtic enters deeply into the composition of the Latin tongue. In proof of this, we need only refer to Pelloutier, Bullet's *Mémoires de la Langue Celtic partie première*, Abbé Pezron's *Origin of Ancient Nations*, and other works of a similar kind. Whether the old Celtic differed essentially from the Pelasgic and Hetruscan, would be a matter of curious investigation, were this a proper subject for the present article.

---

[4] *Vita Romul.*

[5] Strabo, lib. v. Dionysius Halicarnasseus, *Antiq.* lib. i.

[6] Strabo et Herodotus.

[7] Thucydides, lib. vi.

[8] The Hetrusci were variously denominated by the Greeks and Romans. The former called them Τυϱσηνοι, which was their true name, for they actually emigrated from Tarshish, or the western coast of Asia Minor, and consequently Herodotus everywhere calls them Τυϱσηνοι. The Æolians changed α into υ; hence in that dialect they were called Τυρσηνοι, from *Tarsus*. The Romans styled them *Tusci*, probably from the Greek verb ϑυω, *sacrifico*, alluding to the skill which that people professed in the ceremonies of religion. They called their country *Hetruria*, we think from the Chaldaic word *heretum*, a magician or sorcerer; a name deduced from their skill in divination.

The Latin abounds with oriental words, especially Hebrew, Chaldaic, and Persian. These are certainly remains of the Pelasgian and Hetruscan tongues, spoken originally by people who emigrated from regions where such words formed parts of the vernacular language. The Greeks, in polishing their language, gradually distorted and disfigured vast numbers of the rough eastern terms, which formed a very great part of it, as we have already shown in the preceding section.

The Romans, of less delicate organs, left them in their natural state, and their natural air readily betrays their original. We had collected a large list of Latin words still current in the East; but we find that Thomassin[1] and Ogerius,[2] and especially M. Gebelin, in his excellent Latin Dictionary, have rendered that labour superfluous.

In this language, too, there are not a few Gothic terms. How these found their way into the Latin, it is not easy to discover, unless, as Pelloutier supposes, the Celtic and Gothic languages were originally the same; or perhaps it may be conjectured, that such words formed part of a primitive language, which was at one time universal.

ow far e Latin embles e Greek.

There are, besides, in the Latin a great number of obsolete Greek words, which were in process of time obliterated, and others substituted in their stead; so that, upon the whole, we are persuaded, that the most effectual method for distinguishing the difference between the early and modern Greek, would be to compare the ancient Latin with the more recent, especially as there existed very little difference between the ancient Greek and Latin in the earliest periods. But however this may be, it is certain that the Roman letters were the same with the ancient Greek. *Formæ literis Latinis quæ veterrimis Græcorum*, says Tacitus,[3] whilst Pliny[4] states the same thing, and for the truth of his assertion appeals to a monument extant in his own time. These old Greek letters were no other than the Pelasgian, which we have shown from Diodorus Siculus to have been prior to the Cadmean.[5]

That the Latins borrowed the scheme of their declensions from the Greeks, is evident from the exact resemblance of the terminations of the cases throughout the three similar declensions. In nouns of the first declension, the resemblance is too palpable to stand in need of illustration. In the second, the Greek genitive is οι; but in Latin the *o* is thrown out, and the termination becomes *i*. In the section on the Greek language, we have observed, that the sounds of ι and υ differed very little; therefore the Latins used ι instead of υ. The Latin dative ends in *o*, which is the Greek dative, throwing away ι *subscriptum*, which was but faintly sounded in that language. No genuine Greek word ended in μ or *m*. The Hellenes seem to have abhorred that bellowing liquid; it is certain, however, that they imported it from the East, as well as the other letters, and that they employed it in every other capacity, except in that of closing words. In the termination of flexions, they changed into υ. The Latins retained *m*, which had been imported to them as a terminating letter at an era before the Greek language had undergone its last refinement. Hence the Latin accusative in *um*, instead of the Greek in ον. The vocative case, we imagine, was in this declension originally like the nominative. The Latins have no dual number, because, in our opinion, the Æolic dialect, from which they copied, had none. It would no doubt, be a violent stretch of etymological exertion, to derive either the Latin genitive plural of the second declension from the same case of the Greek, or that of the latter from the former; we therefore leave this anomaly, without pretending to account for its original formation. The third declensions in both languages are so exactly parallel, that it would be superfluous to compare them. But even here the dative plural is another anomaly, and we think a very disagreeable one, which we leave to the conjectures of more profound etymologists. For the other peculiarities of Latin nouns, as they are nearly similar to those of the Greek, we must beg leave to refer our readers to that section.

Deficiency of articles.

The Latins have no articles, which is certainly a defect in their language. The Pelasgic, from which they copied, had not adopted that word in the demonstrative sense. Homer indeed seldom uses it; and the probability is, that the more early Greeks used it less frequently, at least in the sense above mentioned. Thus in Latin, when I say, *video hominem*, it is impossible to find out by the bare words whether the word *hominem* intimates a man, or the man, whereas in Greek it would be βλεπω ἀνθρωπον, *I see a man*, βλεπω τον ανθρωπον, *I see the man*. Hence the first expression is indefinite, and the second definite.

Origin of the substantive and of other verbs.

The substantive verb *sum* in Latin seems to be formed partly from the Greek and partly not. Some of the persons of the present tense have a near resemblance to the Greek verb ἐω or ἐιμι, whilst others vary widely from that archetype. The imperfect præterite and præterperfect have nothing in common with the Greek verb, and cannot, we think, be forced into an alliance with it. The future *ero*, was of old *eso*, and is indeed genuine Greek. Upon the whole, in our apprehension, the Latin substantive verb more nearly resembles the Persian verb *hesten* than that of any other language with which we are acquainted.

From what exemplar the Latin verbs were derived, it is by no means easy to ascertain. We know that attempts have been made to deduce them all from the Æolic Greek, and that the Romans themselves were extremely fond of this chimera; but the almost numberless irregularities, both in the formation and conjugation of their verbs, induce us to believe that only a part of them were formed upon that model. We are inclined to think that the terminations in *bam, bas, bat, bamus*, &c. were produced by their union with a fragment of some obsolete verb, which is now wholly lost. In the verb *amo*, for instance we are sure that the radix *am* is the Hebrew word *mother;* but how *am-abam, am-abo, am-arem* were fabricated, and connected with the radical *am*, is not so easily determined. That Latin verbs, as well as the Greek, are composed of an inflexible radix and another flexible verb, cannot be doubted; but what this flexible auxiliary was, cannot now be clearly ascertained. It is not altogether improbable that such parts of the verbs as deviate from the Greek archetype were supplied by fragments of the verb *ha*, which pervades all the branches of the Gothic language, and has, we conceive produced the Latin verb *habeo*. When the Greeks began to etymologise, they seldom overpassed the verge of their own language; and the Latins pursued nearly the same course. If their own language presented a plausible etymology, they embraced it; if not, they immediately had recourse to the Greek; and this was the *ne plus ultra* of their etymological researches. Cicero, Quintillian, Festus, and even Varro, the most learned of all the Romans, stop here; all beyond is either doubt or impenetrable darkness. Their opinion above mentioned we offer only as a conjecture; as to the decision we leave it to more able critics.

---

[1] Glossary.

[5] For the figure of these letters, see Astle, Postellus, Montfaucon, *(Palægraphia Græca,)* M. Gebelin, and others.

Deficiencies in Latin verbs.

The want of aorists or indefinite tenses seems to us to be a palpable defect in the Latin language. The use of these amongst the Greeks entitled the writer to express the specific variations of time with more accuracy and precision than the Latins, who never attempted to specify them by any other tenses but the imperfect and pluperfect. Indeed we should imagine, that both the Greeks and Latins were much inferior to the English in this respect. The Latin word *lego*, for example, may be translated into English three different ways; as, *I read, I do read*, and *I am reading*.

Irregularities in the conjugations.

The Latins, in reducing their verbs to four conjugations, formed their inflexions in a very irregular manner. Numbers of the first class inflect their præterite and supine like those of the second; thus, *domo*, instead of giving *avi* and *atum*, has *ui* and *itum*, like *monui* and *monitum*. Again, not a few verbs of the third conjugation have *ivi* and *itum*, as if they belonged to the fourth; e. g. *peto, petivi, petitum*. Then, some verbs have *io* in the present, *ivi* in the præterite, and *itum* in the supine, whilst, contrary to the rules of analogy, they in reality belong to the third; such are *cupio, cupivi, cupitum, cupere*, and others. Some verbs of the second conjugation have their præterite and supine as if they belonged to the third; thus, *jubeo, jussi, jussum, jubere*, and *augeo, auxi, auctum, augere*. Some verbs, which are actually of the fourth conjugation, have their præterite and supine as if they were of the third; thus, *sentio, sensi, sensum, sentire*, and *haurio, hausi, haustum, haurire*. If these are not manifest irregularities, we cannot say what deserves the name. The fact seems to stand thus. The Romans were originally a banditti of robbers, bankrupts, runaway slaves, shepherds, husbandmen, and peasants of the most unpolished character. They were engaged in perpetual broils and quarrels at home, and seldom enjoyed repose abroad. Their profession was robbery and plunder. Like old Ishmael, their hands were against every man, and every man's hand was against them. In such a state of society no time was left for cultivating the sciences. Accordingly, the arts of war and government were their sole profession. This is so true, that their own poet has characterized them in the following manner:—

> Excudent alii spirantia mollius aera,
> Credo equidem: vivos ducent de marmore vultus;
> Orabunt causas melius; coelique meatus
> Describent radio, et surgentia sidera dicent:
> Tu regere imperio populos, Romane, memento:
> Hae tibi erunt artes: pacisque imponere morem,
> Parcere subjectis, et debellare superbos.

The Latin deficient in participles.

Another blemish in the Latin language is occasioned by its wanting a participle of the præterite sense in the active voice. This defect is perpetually felt, and is the cause of an awkward circumlocution wherever it happens to present itself. Thus, *Imperator, cum transiiset flumen, aciem instruxit;* the general having crossed the river drew up his army. Here *cum transiiset flumen* is a manifest circumlocution, which is at once avoided in the Greek ὁ ἡγεμων περασας τον ποταμον, κ. τ. λ. This must always prove an incumbrance in the case of active intransitive verbs. But when active deponent verbs occur, it is easily avoided. Thus, *Cæsar cohortatus milites, prælii committendi signum dedit;* Cæsar having encouraged the soldiers, gave the signal for joining battle. Another palpable defect in this language arises from the want of a participle of the present passive. This again must be productive of inconvenience upon many occasions, as will be obvious to every Latin student.

Supines and gerunds.

The two supines are universally allowed to be substantive nouns of the fourth declension. How these assumed the nature of verbs it is not easy to determine. When they are placed after verbs or nouns, the matter is attended with no difficulty; but how they should acquire an active signification, and take the case of the verb with which they are connected, is not so easily accounted for, and certainly implies a stretch of prerogative. The Latin gerunds form another unnatural anomaly. Every scholar knows that these words are nothing but the neuters of the participles in *dus* of the future passive. The fabricators of the Latin language, however, elevated them from their primary condition, giving them upon many occasions an active signification. In this case we must have recourse to the

> Si volet usus,
> Quem penes arbitrium est, et jus et norma loquendi.

Another inconvenience, which is perhaps more severely felt than any of the preceding, arises from the want of the use of the present participle of the verb *sum*. Every body knows what a convenience is derived from the frequent use of the participle ὢν in Greek; and indeed it appears to us somewhat surprising that the Latins neglected to introduce the participle *ens* into their language. In this we believe they were singular. Here again a circumlocution becomes necessary. In such a case as the following, "The senate being at Rome, passed a decree," instead of saying *senatus ens Romæ, legem tulit*, we are obliged to say *cum senatus Romæ esset, legem tulit*. If the words *ens* or *existens* had been adopted, as in the Greek, this odious circumlocution would have been avoided. Many other defects of a similar kind will occur to every person who shall choose to search for them, and these, too, in the most approved classical authors.

Different genius of the Latin and Greek languages.

If any one will take the trouble to compare the structure of the Greek and the Latin languages, he may very soon be convinced that their characteristic features are extremely different. The genius of the former appears easy and natural; whereas that of the latter, notwithstanding the united efforts of the poets, orators, and philosophers, who wrote in it, still bears the marks of violence and restraint. Hence it appears that the Latin language was pressed into the service, and compelled almost against its peculiar genius to bend to the laws of the Grecian model. Take a sentence of Hebrew, Chaldaic, Arabian, or Persian, and try to translate it into Greek without regarding the arrangement of the words, and you will find it no difficult task; but make the same trial with respect to the Latin, and you will probably discover that the attempt is attended with considerable difficulty. To translate Greek into English is not a laborious task; the texture of the two languages is so congenial, that the words and phrases, and even the idiomatic expressions, naturally slide into each other. But with the Latin the case is quite otherwise; and before elegant English can be produced, one must deviate considerably from the original. Should we attempt to translate a piece of English into Greek, and at the same time into Latin, the translation of the former would be attended with much less difficulty than that of the latter, supposing the translator to be equally skilled in both languages.

Causes of this differ ence.

This incongruity seems to spring from the following cause. Before any man of considerable abilities, either in the capacity of a poet, grammarian, or rhetorician, appeared at Rome, the language had acquired a strong and inflexible tone, too stubborn to be exactly moulded according to the Grecian standard. After a language has continued several centuries without receiving a new polish, it becomes like a full grown tree, incapable of being bent to the purposes of the mechanic. For this reason, it is highly probable, that the language in question could not be forced into a complete assimilation with the Greek. But notwithstanding all these obstructions, in process of time it arrived at such an exalted pitch of perfection, as to rival, perhaps to excel, all the other European languages, Greek only excepted. Had men possessing the taste, judgment, and industry of Ennius, Plautus, Terence, Cicero, and the worthies of the Augustan age, appeared in the early stages of the Roman commonwealth, their language would have been thoroughly reduced to the anguage.

Grecian archetype, and the two dialects might have improved each other by a rivalship between the nations who employed them.

Without pretending to encumber our readers with a pompous and elaborate account of the beauties of that imperial language, which have been detailed by writers almost without number, we shall endeavour to lay before them as briefly as possible its pristine character, the steps by which it gradually rose to perfection, the period when it arrived at the summit of its excellence, and the means by which it rapidly degenerated until it was finally lost amongst the very people to whom it had owed its birth.

he Latin mposed iefly of elasgic d Celtic ords.

We have observed already, that the Latin was originally a *colluvies* of all the languages spoken by the vagrant people who composed the first elements of that republic. The prevailing dialects were the Pelasgian or Etruscan, which we conceive to have been the same; and the Celtic, which was undoubtedly the aboriginal idiom of Italy. Hence the primary dialect of the Romans was composed of discordant materials, which in our opinion never acquired a natural and congenial union. The Pelasgian or Etruscan part of it retained a strong tincture of the oriental style. But the Celtic portion appears to have been the prevalent one, since we find that most of the names of places, especially in the middle and northern parts of Italy, are actually of Celtic origin.[1] It is clear therefore that the dialect of the first Romans was composed of the languages above mentioned. Who those first Romans were, it is impossible to determine with any degree of certainty; indeed the Roman historians afford us as little information upon the subject, as their etymologists do respecting the origin of their language. Their most celebrated writers upon this point were Ælius Gallus, Quintus Cornificius, Nonius Marcellus, Festus, and some others of less note. At the head of these we ought to place Terentius Varro, whom Cicero styles the most learned of all the Romans. But from such writers we need expect no light. Their etymologies are generally childish and futile. Of the language of the most ancient Romans we can only reason by analogy; and by that rule we can discover nothing more than what has already been advanced.

We may rest assured that the dual number, the articles, the participle above mentioned, the aorists, and the whole middle voice, never appeared in the Latin language; and for this reason that they were not current in those languages from which it was derived, at least at the time when it was first fabricated. Besides all this, many circumstances concur to make it highly probable that, in the earliest period of the language, very few inflexions were introduced. First, when the Pelasgians left Greece, the Greek language itself was not fully polished. Secondly, the Arcadians were never thoroughly civilized. They were a rustic pastoral people, and minded little the refinements of a civilized state; consequently the language which they brought into Italy at that era must have been of a coarse and irregular contexture. Thirdly, when the Thessalian Pelasgians arrived in Italy about the time of Deucalion, the Greek language itself was rude and barbarous;[2] and, which is of still more consequence, if we may credit Herodotus quoted in the former section, the Greek people had never adopted the Hellenic tongue. Hence it appears, that the part of the Latin language derived from the Pelasgian or Etruscan must have taken a deep tincture from the oriental tongue. If we may judge of the Celtic of that age by the Celtic of the present, the same character must likewise have distinguished its structure.

iginally le in- cted.

Latin Language.

From these circumstances, we think it appears that the earliest language of the Romans was but very little diversified by means of inflections. It nearly resembled the oriental exemplar, and consequently differed widely from the modern Latin. The effect of this was, that the modern Romans could not understand the language of their early progenitors. Polybius,[3] speaking of the earliest treaty between the Romans and Carthaginians, makes the following observation: "Believe me," says he, "the Roman language has undergone so many changes since that time to the present, that even those who are most deeply skilled in the science of antiquities cannot understand the words of that treaty except with the greatest difficulty."[4] From this source, then, has flowed that great number of oriental words with which the Latin language is impregnated. Being originally inflexible, they were not disguised as they now are with prefixes, affixes, metatheses, syncopes, antitheses, and the like, but plain and unadorned in their natural dress.

Afterwards formed on the Greek model.

After the Romans had become acquainted with the Æolian Greeks, who gradually seized upon both coasts of Italy towards the south, which they called Magna Græcia, they began to affect a Grecian air, and to torture their language into a foreign contexture. It appears, however, that at first the Grecian attire had rather an awkward appearance, and that several marks of violence were easily discerned. The most ancient specimen of this kind that we can recollect consists of the remains of the Twelve Tables. Here every thing is rude and of a clumsy cast; for although by this time considerable progress had been made in refinement, and the language of Rome had begun to appear in a Grecian uniform, still those changes were not altogether natural. Soon afterwards appeared Marcus Fabius Pictor and Sisenna, historians often quoted by Livy, but whose works have long since been irrecoverably lost. The Fasti Capitolini are frequently mentioned; but they too perished in the burning of the Capitol during the civil wars between Marius and Sylla. If those monuments had escaped the ravages of time, we should have been able to mark the progress of the Latin language from stage to stage, and to ascertain with the greatest accuracy its gradual configuration in the course of its progress towards the Grecian standard. We must therefore abandon the attempt to trace the Latin during those rude and barbarous periods, and descend to others which are better known and more characteristically marked. The latter, commenced when

> Græcia capta ferum victorem cepit, et artes
> Intulit agresti Latio.

The authors by whom it was polished.

In this period flourished Ennius, who wrote in eighteen books, a Roman history in hexameter verse, which he called *Annals*, the greater part of which is now unhappily lost. He likewise translated Euhemerus *de Origine Deorum*, a work often mentioned by the Christian fathers in their disputes with the Pagans, and which is sometimes quoted by Cicero. Then followed Caius Lucilius the famous satirist, and a number of other writers, such as Accius, Valerius, Ædituus, Alpinus, whose fragments were published by the Stephens, at Paris, in 1564. All these imitated the writers of Greece or translated from them. By their perseverance and active exertions, the spirit of the Greek authors was transfused into the Latin language, and its structure accommodated to the Grecian standard.

Plautus and Terence, by translating into their own language, the comedies of Menander and Diphilus taught the Latin muses to breathe their inspirations in Attic Greek. To speak that language was then the fashion of the times, as it is now with us to chatter French. Greek tutors were retained in every reputable family; and many Romans of the first rank were equally qualified to speak or write both in Greek and in Latin. The original jargon of Latium had now become obsolete and unintelligible; and even Cato the Ancient condescended to learn the Greek language at the age of eighty.

---

[1] For proof of this our readers may consult Abbé Pezron, Pelloutier, Bullet's *Mémoires*, Gebelin, *Præf. Dict. Lat.* and many others.

[2] Dionysius Halicarnasseus, lib. i.

[3] See his History, lib. iii. *sub initio.*

[4] This treaty, according to the same historian, was concluded in the consulship of Lucius Junius Brutus and Marcus Valerius, twenty-eight years before Xerxes made his descent upon Greece.

Golden age of Rome.

To pretend to enumerate the various, and we may add inimitable, examples of the Augustan or golden age of the Roman language, would be an insult to the understanding of our readers. We shall only take the liberty to translate a few lines from an able and excellent historian,[1] who, had his honesty been equal to his judgment, might have rivalled the most celebrated writers of his country. Having observed that the Greek authors, who excelled in every province of literature, had all made their appearance nearly about the same time, and within a very short space of one another, he adds: “Nor was this circumstance more conspicuous amongst the Greeks than amongst the Romans; for unless we go back to the rough and unpolished times, which deserve commendation only on account of their invention, the Roman tragedy is confined to Accius and the period when he flourished. The charming wit of Latin elegance was brought to light by Cecilius, Terentius, and Afranius, nearly in the same age. As for our historians if we except Cato and some old obscure writers, they were all confined to a period of about eighty years; so neither has our stock of poets extended to a great space either backwards, or forwards. But the energy of the bar, and the finished beauty of prose eloquence, setting aside the same Cato (by the leave of Crassus, Scipio, Lælius, the Gracchi, Fannius, and Ser. Galba, be it spoken), broke out all at once under Tully the prince of his profession; so that one can now be delighted with none before him, and admire none except such as have either seen that orator or been seen by him.”

Causes of the degeneracy of the Latin language.

From this quotation it evidently appears, that the Romans themselves were convinced of the short duration of the golden age of their language. According to the most judicious critics, it commenced with the era of Cicero's oratorical productions, and terminated with the reign of Tiberius, or rather, perhaps, it did not reach beyond the middle of that prince's reign. It is generally believed that eloquence, and with it every thing liberal, elevated, and manly, was banished from Rome by the despotism of the Cæsars. But we imagine that the transition was too instantaneous to have been entirely produced by that cause. Despotism was firmly established amongst the Romans about the middle of the reign of Augustus; and yet that period produced such a group of learned men as never perhaps adorned any other nation in so short a space of time. Despotism, we acknowledge, might have affected the eloquence of the bar, the noble and important objects which had animated the republican orators being now no more; but this circumstance could not affect poetry, history, philosophy, and jurisprudence. The style employed upon these subjects did not feel the fetters of despotism. The reign of Louis XIV. was the golden age of the French language; and we think that age produced a race of learned men, in every department superior in number and equal in genius to the literati who flourished under the noble and envied constitution of Britain during the same period, although the latter is likewise said to have been the golden age of this country. The British Islands, we conceive, still enjoy as much liberty as ever; yet we believe there are few persons who will affirm, that the writers of the present day are equal either in style or in genius to that noble group who flourished from the middle of the reign of Charles I. to the middle of the reign of George II.

In the East the same observation seems to hold true. The Persians have long groaned under the Mohammedan yoke; and yet every oriental scholar will allow, that in that country, and under the most galling tyranny, the most amazing productions of taste, genius, and industry, that ever dignified human nature, have been exhibited. Under the Arabian caliphs, the successors of Mohammed, appeared writers of a most sublime genius, although despotism was never more cruelly exercised than under those fanatics. The revival of letters in Italy during the fourteenth century, was chiefly promoted and cherished by the petty despots of that country. We cannot therefore be persuaded that the despotism of the Cæsars banished eloquence and learning from Rome. Longinus indeed has attributed this misfortune to the cause just stated, and tells us, that it is liberty which is formed to nurse the sentiments of great geniuses, to push forward the propensity of contest, to inspire them with the generous ambition of being the first in the first rank. But when Longinus wrote this, he did not reflect that he himself was a striking instance of the unsoundness of his own observation.

The writers of the silver age

As to science, the fact is undoubtedly on the other side. That Seneca was superior to Cicero in philosophy, cannot be reasonably contradicted. The latter had read, and actually abridged, the whole mass of Grecian philosophy; but this displayed his reading rather than his learning. The former had addicted himself to the Stoic sect; and though he does not write with the same flow of eloquence as Tully, he thinks more deeply and reasons more closely. Pliny's Natural History is indeed a wonderful collection, and contains more useful knowledge than all the writings of the Augustan age condensed into one mass. The historical annals of Tacitus, if inferior to Livy in elegance of style and majesty of diction, are much superior in arrangement and in vigour of composition. In short, we discover in these productions a deep insight into human nature, an extensive knowledge of the true science of government, a penetration which no dissimulation could escape, together with a sincere attachment to truth respecting both events and characters; nor is he inferior in the majesty, energy, and propriety of his harangues, wherever an equal opportunity presents itself. Quintilian, Pliny the younger, Suetonius, Petronius Arbiter, and Juvenal deserve high commendation, and are not inferior to their immediate predecessors. We think there is good reason to conclude, that the loss of liberty amongst the Romans did not produce the extinction of eloquence, science, elevation of sentiment, or refinement of taste. The circumstances which chiefly contributed to produce that revolution were of a different description.

Velleius Paterculus whom we have already quoted assigns some very plausible and judicious reasons for the catastrophe in question. “Emulation,” says he “is the nurse of genius; and one while envy, and another admiration fires imitation. According to the laws of nature, that which is pursued with the greatest ardour mounts to the top; but to be stationary in perfection is a difficult matter; and by the same analogy, that which cannot move forward must go backward. As at the outset we are animated to overtake those whom we deem before us, so when we despair of being able to overtake or to pass by them, our ardour languishes together with our hope; what it cannot overtake it ceases to pursue, and leaving the subject as already engrossed by another, it looks out for some new one upon which to exert itself. That by which we find that we are not able to acquire eminence we speedily relinquish, and try to discover some object elsewhere upon which to employ our intellectual powers. The consequence is, that frequent and variable transitions from subject to subject prove a great obstacle to the attainment of perfection in any profession.”

This was perhaps the case with the Romans. The heroes of the Augustan age had borne away the prize of eloquence, history, poetry, and elegant literature; and their successors despaired of being able to equal, much less to surpass them, in any of these pursuits. They were therefore placed under the necessity of striking out a new path by which they might hope to arrive at eminence. Consequently Seneca introduced the *stile coupé*, as the French call it; that is, a short, sparkling, figurative diction, abounding with antitheses, quaintnesses, witticisms, and embellished with meretricious ornaments; whereas the style of the Augustan age was natural, simple, solid, unaffected, and properly adapted to the nature of the subject as well as to the sentiments of the author.

---

[1] Velleius Paterculus, lib. i cap. *ult.*

The historian Sallust laid the foundation of the unnatural style here mentioned. Notwithstanding all the excellencies of that celebrated author, he everywhere exhibits an affectation of antiquity, an antithetical cast, an air of austerity, an accuracy, exactness, and regularity, the very opposite of that *air degagé* which nature displays in her most finished efforts. His words and his clauses seem to be adjusted exactly according to number, weight, and measure, without either excess or defect. Valleius Paterculus imitated this writer; and, as is generally the case with imitators, succeeded best in those points where his archetype had failed most egregiously. Tacitus, however excellent in other respects, deviated from the Augustan exemplars, and is thought to have imitated Sallust; but affecting brevity to excess, he often falls into obscurity. The other contemporary writers employ a cognate style; and because they have deviated from the Augustan standard, their works are held in less estimation, and are thought to bear about them marks of degeneracy. This degeneracy, however, did not spring from the despotic government under which these authors lived, but from the affectation of singularity into which they were betrayed by an eager though fruitless desire of signalizing themselves in the new mode, as their predecessors had done in the old.

But the mischiefs of this rage for innovation did not reach their sentiments, as it had done their style; for in that point we think they were so far from falling below the measure of the writers of the former age, that in many instances they appear to have surpassed them. With respect to sentiment and mental exertions, the authors in question preserved their vigour, till luxury and effeminacy, the consequence of power and opulence, enervated both the bodies and the minds of the Romans. The contagion soon became universal; and a listlessness, or intellectual torpor, the usual concomitant of luxury, spread an indolence over the mental faculties, which rendered them not only averse to, but even incapable of, industry and perseverance. This lethargic disposition of mind seems to have commenced towards the conclusion of the silver age; that is, about the end of the reign of Hadrian. It was then that the Roman eagle began to stoop, and that, in arts as well as in arms, the genius of Rome showed symptoms of decline.

As the Roman genius began, about this period, to decline, so the style of the silver age became gradually vitiated with barbarisms and exotic forms of speech. The multitudes of barbarians who flocked to Rome from all parts of the empire; the ambassadors of foreign princes, and often the princes themselves, with their attendants; the prodigious numbers of slaves who were entertained in all the considerable families of the capital, and throughout Italy; the frequent commerce which the Roman armies upon the frontiers carried on with the barbarians; all concurred to vitiate the Latin language, and to interlard it with foreign words and idioms. In such circumstances, it was impossible for that or any other form of speech to continue pure and untainted. But this vitiated character both of style and of sentiment became more and more prevalent, in proportion as it descended from the reign of Hadrian towards the era of the removal of the seat of empire from Rome to Constantinople. Then succeeded the iron age, when the Roman language became absolutely rude and barbarous.

Writers during the silver and brazen ages.

Towards the close of the silver, however, and during the whole course of what is called the brazen age, there appeared many writers of no contemptible talents. The most remarkable was Seneca the stoic, the master of Nero, whose character both as a man and a writer is discussed with great accuracy by the noble author of the *Characteristics*, a work to which our readers are referred. About the same time lived Persius the satirist, the friend and disciple of the stoic Cornutus, to whose precepts he did honour by his virtuous life; whilst by his works, though few, he showed an early proficiency in the science of morals.

Under the mild government of Hadrian and the Antonines lived Aulus Gellius, or, as some call him, Agellius; an entertaining writer in the miscellaneous way, and well skilled in criticism and antiquity. His works contain several valuable fragments of philosophy, which are indeed the most curious part of them. With Aulus Gellius we may rank Macrobius; not because he was a contemporary, for he is supposed to have lived under Honorius and Theodosius, but from his close resemblance in the character of writer. His works, like those of Gellius, are miscellaneous, being filled with mythology and ancient literature, intermixed with some philosophy. In the same age with Aulus Gellius flourished Apuleius of Madaura in Africa; a Platonic writer, whose matter in general far exceeds in merit his perplexed and affected style, which is but too conformable to the false rhetoric of the age in which he lived.

Boethius was descended from one of the noblest of the Roman families, and was consul in the beginning of the sixth century. He wrote many philosophical works; but his ethical work on the Consolation of Philosophy deserves great encomiums, both for the matter and the style, in which last respect, he approaches the purity of a far better age than his own. By command of Theodoric the king of the Goths this great and good man suffered death; and with him the Latin language, and the last remains of Roman dignity, may be said to have sunk in the western world. There were, besides, a goodly number both of poets and historians who flourished during this period, such as Silius Italicus, Claudian, Ausonius, and others, for a list of whom the reader may consult Fabricii *Bibliotheca Latina*. A number of ecclesiastical writers, some of whom deserve great commendation, also flourished about the same period. The chief of these is Lactantius, who has been deservedly dignified with the proud title of the *Christian Cicero*.

The Roman authors amount to a very small number in comparison of the Greek. At the same time, when we consider the extent and duration of the Roman empire, we are surprised to find so few writers of character and reputation in so vast a field, and think we have good reason to agree with the prince of Roman poets in the sentiment which has been already quoted.

Excellency and usefulness of the Latin language.

Upon the whole, the Latin language deserves our attention beyond any other ancient tongue now extant. The grandeur of the people by whom it was spoken; the high genius of its writers; the empire which it still maintains amongst ourselves; the necessity we are under of learning it in order to obtain access to almost all the sciences, nay even to the knowledge of our own laws, judicial proceedings, and charters; all these circumstances, and many others too numerous to be detailed, render the acquisition of that imperial and universal language in a peculiar manner at once improving and interesting. Spoken by the conquerors of the ancient nations, it partakes of all their revolutions, and bears continually their impression. Strong and nervous whilst they were employed in nothing but battles and carnage, it thundered in the camps, and made the proudest people to tremble, and the most despotic monarchs to bend their stubborn necks to the yoke. Copious and majestic, it became the learned language of Europe, when the Romans, weary of battles, inclined to vie with the Greeks in science and refinement; and by its lustre it caused to disappear the jargon of savages which disputed with it the possession of that quarter of the globe. After having controlled by its eloquence, and humanized by its laws, all those tribes, it became the language of religion; and it will continue to be studied and esteemed as long as good sense and classical taste remain in the world.

SECT. IX. CELTIC, GOTHIC, AND SCLAVONIAN LANGUAGES.

§ 1. *Of the Celtic Language.*

In treating of the origin of the Latin language, we observed that a great part of it had been derived from the Celtic. We shall now endeavour to give some account of the origin and extent of that ancient language, leaving the minutiæ to grammars and dictionaries, as we have done with respect to the other dialects which have fallen under our consideration. The object of this treatise is to discuss questions in philology alone, not to enter into grammatical details, or lexicographical explanations.

The Gauls or Celts.

The descendants of Japhet having peopled the western parts of Asia, at length entered Europe. Some broke into that quarter of the globe by the north, and others found means to cross the Danube near its mouth. Their posterity gradually ascended towards the source of that river; but afterwards they advanced to the banks of the Rhine, which they passed and thence spread themselves as far as the Alps and the Pyrenees.

These people, were, in all probability, composed of different families; all of them, however, spoke the same language; their manners and customs bore a near resemblance; and there was no variety amongst them except that difference which climate always introduces. Accordingly, they were all known, in the more early times, by the general name of *Celto-scythæ.* In process of time, becoming exceedingly numerous, they were divided into several nations, which were distinguished by different names and territorial appellations. Those who inhabited that large country which is bounded by the ocean, the Mediterranean, the Rhine, the Alps, and the Pyrenees, were denominated Gauls or Celts. This people multiplied so prodigiously in the space of a few centuries, that the fertile regions which they then occupied could not afford them the means of subsistence. Some of them now passed over into Britain; others crossed the Pyrenees, and formed settlements in the northern parts of Spain. Even the formidable barrier of the Alps could not impede the progress of the Gauls. They made their way into Italy, and colonized those parts which lie at the foot of these mountains, whence they extended themselves towards the centre of that rich country.

By this time the Greeks had landed on the south-eastern coast of Italy, and founded numerous colonies in those parts. The two nations having each apparently a redundant population, and always planting colonies in the course of their progress, at length met about the middle of the country. This central region was at that period called Latium; and here the two nations formed one society, which was called the Latin people. The languages of both nations were blended together; and hence, according to some, the Latin is a mixture of Greek and of Celtic.

Their language.

As the Gauls were a brave and numerous people, they certainly maintained themselves in their pristine possessions, uninvaded and unconquered, until their civil animosities and domestic quarrels exposed them as a prey to those very Romans whom they had so often defeated, and sometimes driven to the brink of destruction. They were not a people addicted to commerce; and upon the whole, considering their situation both in their primary seats and afterwards in Italy, they had little temptation or opportunity to intermingle with foreigners. Their language, therefore, must have remained unmixed with foreign idioms. Such as it was when they settled in Gaul, such it must have continued until the Roman conquests. If therefore there is one primitive language now existing, it must be found in the remains of the Gaulic or Celtic. It is not, then, surprising, that some very learned men, upon discovering the coincidence of great numbers of words in some of the Greek dialects with other words in the Celtic, have been inclined to establish a strict affinity between these languages. The ancient Pelasgic and the Celtic must at least have nearly resembled each other; admitting only a dialectical difference, and that discrimination which climate and a long period of time must always produce.

Some writers have thought that the Gauls lost the use of their native language soon after their country was conquered by the Romans; but M. Bullet, in his *Mémoires de la Langue Celtique*, has proved almost to demonstration, that the vulgar amongst this people continued to speak it several centuries after that period. When a great and populous nation has for many ages employed a vernacular idiom, nothing can ever make them entirely relinquish the use of it, and adopt unmixed that of their conquerors.

Many learned men, amongst whom is the lexicographer above mentioned, have shown that all the local names in the north of Italy are actually of Celtic extraction. These names generally point out or describe some circumstances relating to the physical character of the situation; such as exposure, eminence, lowness, moistness, dryness, coldness, heat, and the like. This is a very characteristic feature of an original language; and in the Celtic it is so prominent, that the Erse names of places all over Scotland, are, even to the present day, peculiarly distinguished by this quality. We have heard a gentleman, who was well skilled in that dialect of the Celtic still spoken in the Highlands of Scotland, propose to lay a bet at very great odds, that if any one should pronounce the name of any village, mountain, river, gentleman's seat, or other place, in the old Scottish dialect, he would be able, by its very name, to give a pretty exact description of its local situation.

Sources whence t Celtic w derived.

To discover the real sources from which the Celtic language was derived, we must have recourse to various expedients. In the first place, we must consult the Greek and Latin authors, who have preserved some Gaulic or Celtic terms in their writings. Secondly, we must have recourse to the Welsh and *Basse Brétagne* dialects, in which, indeed, there are many new words, though these are easily distinguishable from the primitive stock. Thirdly, if we would trace another source of the Celtic, we must converse with the country people and peasants, who live at a distance from cities, in those countries where this was once the vernacular tongue. We have been credibly informed, that a Highland gentleman crossing the Alps on his way to Italy, accidentally met with an old woman, a native of those parts, who spoke a language so nearly akin to his native Erse, that he could understand her with little difficulty; and that she, on the other hand, understood most of his words. That an event of this nature should actually take place is by no means surprising, when we consider that the dialect spoken in the Highlands of Scotland is perhaps the most genuine remnant of the Celtic now existing, and at the same time reflect that there may be remote cantons amongst those wild and inaccessible mountains, the Alps, where some remains of that tongue may still be preserved. Fourthly, we have said that the most genuine remains of the Gaelic tongue are to be found in the Highlands of Scotland. The reason of this is obvious. The Scottish Highlanders are the unmixed unconquered posterity of the ancient Britons, into whose barren domains the Romans never penetrated; not, we imagine, because they were not able, since they subdued both North and South Wales, equally inaccessible, but because they found no inducement either to excite their ambition or provoke their avarice. Amidst all the revolutions which from time to time shook and convulsed Albion, these mountainous regions were left to their primitive lords, who, though like their southern progenitors, hospitable in the extreme, did not suffer strangers to reside long amongst them. Their language, accordingly, remained unmixed, and in a great measure continues so even unto this day, especially in the most remote parts and unfrequented islands.

The Norwegians subdued the western islands of Scotland, at a time when the Scottish monarchy was still in its minority; and the same people erected a kind of principality over them, of which the Isle of Man was the capital. But though they maintained the sovereignty of these islands for some centuries, built many forts, which they strengthened with garrisons, and were the lawgivers and administrators of justice amongst the natives, yet we have been informed by the most respectable authority, that there is not at this day a single term of the Norse or Danish language to be found in use amongst these islanders. This fact demonstrates the superstitious attachment with which they adhered to their vernacular dialect.

T Welsh di ect.

The Welsh dialect cannot, we should think, be pure and unsophisticated. The Silures were conquered by the Romans, to whom they were actually subject for the space of three centuries. During this period a multitude of Italian exotics must have been transplanted into their language; and indeed many of them are discernible at this day. Their long commerce with their English neighbours and conquerors has also adulterated their language, so that a great part of it is now of an English complexion. The Irish is still spoken by a large portion of the native population of Ireland. The historians of that country have brought the Milesian race from the confines of Asia, through a variety of adventures, to people an island *extra anni solisque vias*. But however much this genealogical fable may please the people for whom it was fabricated, we may still suspect that the Irish are of Celtic extraction, and that their forefathers emigrated from the western coast of Britain at a period anterior to all historical or even traditional annals. Ireland was once the native land of saints; and the principal actors on this sacred stage were Romanists, deeply tinctured with the superstition of the times. They pretended to improve the language of the natives; and whatever their success may have been, they improved it in such a manner as to make it deviate very considerably from the original Celtic; so that it is not in Ireland that we are to look for the genuine characters of the language which we are now considering.

C ci- de be- tw n the C c and P nician.

Though, in our opinion, the Hibernian dialect differs considerably from the original Celtic, yet some very ingenious essays have been published by the learned and laborious members of the *Antiquarian Society of Dublin*, in which the coincidence of that idiom with some of the oriental dialects, has been supported by very plausible arguments. In a dissertation published in the year 1772, the authors have exhibited a collection of *Punico-Maltese* words compared with words of the same import in Irish, and it must be allowed that in these the resemblance is palpable. In the same dissertation they have compared the celebrated Punic scene in Plautus with its translation into the Irish, and shown that the words in the two languages are surprisingly similar. If these criticisms are well founded, they tend to prove that the Celtic is coeval and congenial with the most ancient languages of the East; a conclusion which we think highly probable. But however this may be, the Danes and Norwegians formed settlements in Ireland; and the English have long been the sovereigns of that island. These circumstances must have affected the vernacular idiom of the natives, and not to mention the necessity which the people were under of adopting the language of the conquerors in law, in sciences, and in the offices of religion, they must have contributed much to impair its original purity.

The inhabitants of the Highlands and Islands of Scotland are the descendants of those Britons who fled from the power of the Romans, and sheltered themselves amongst the rocks and fastnesses of those rugged mountains and sequestered glens. They preferred the wastes and wilds of the north, with liberty and independence, to the pleasant and fertile valleys of the south, where plenty was embittered by slavery. They no doubt carried their language along with them, and that language was a branch of the Celtic. With them, probably, fled a number of the druidical priests,[1] who unquestionably knew their native dialect in all its beauties and varieties. In process of time these fugitives formed a regular government, elected a king, and became a considerable state. They were sequestered by their situation from the rest of the world. Without commerce, without agriculture, without the mechanical arts, and without objects of ambition or emulation, they addicted themselves wholly to the pastoral life as their business, and to hunting and fishing as their diversion. This people were not distinguished by an innovating genius; and consequently their language must have remained in the same state in which they received it from their ancestors. They received it genuine Celtic, and such they preserved it.

When the Scots had become masters of the low country, and their kings with a great part of the nobility embraced the Saxon manners, and adopted the Saxon language, the genuine Caledonians still tenaciously retained their native dialect, dress, manners, clanships, and feudal customs, and never cordially assimilated with their southern neighbours. Their language, therefore, could not be polluted with words or idioms borrowed from a people whom they hated and despised. Indeed, it is plain from the whole tenor of the Scottish history, that neither Caledonian chiefs, nor their vassals were ever steadily attached to the royal family after they fixed their residence in the low country, and became *Sassenach*, as the Highlanders called them by way of reproach. Indeed, the commerce between them and those of the south, till about a century and a half ago, was only transient and accidental; nor was their native dialect in any material degree affected by this casual intercourse.

Causes of the purity of this dialect of Celtic.

Their language, however, did not degenerate, because there existed amongst them a description of men whose profession obliged them to guard against that misfortune. Every chief retained in his family a bard or poet laureate, whose province it was to compose poems in honour of his lord, to commemorate the glorious exploits of his ancestors, and to record the genealogy and connections of the family; in a word, to amuse and entertain the chief and his guests at all public entertainments, and upon all solemn occasions. These professors of the poetical art used to contend with each other; and the chiefs of families often assembled their respective bards, and encouraged them by considerable premiums to exert their poetical talents. The victor was rewarded and honoured; and the chief deemed it an honour to himself to entertain a bard who excelled his brethren in song. The ancient Gauls, as we learn from Diodorus Siculus, Strabo, Tacitus, Lucan, and others, entertained persons of that profession; and certainly the ancient Britons did the same. The bards were highly revered; their persons were deemed sacred; and they were always rewarded with salaries in lands or in cattle. The members of this tuneful fraternity must have watched over their vernacular dialect with the greatest care and anxiety; because in their compositions no word was to be lost, and as many as possible gained.

---

[1] The probability here assumed cannot very easily be admitted, because we have little else than conjecture to guide us. Mr. Malcolm Laing, in his Dissertation on Ossian, has shown that the opinion expressed in the text is altogether unsupported by any thing deserving the name of evidence; he even contends, that the probability is strongly the other way; and those ancient remains, which have so often been appealed to, as favouring the opinion in question, are considered as of Runic, not Druidical origin. Besides, in the traditional superstitions of the Highlands, there is nothing as far as we know, accords with the account given by Cæsar of the religious rites practised by the British Druids.

The use of letters was not known amongst the ancient *Celtæ;* indeed their druidical clergy forbade the use of them. All their religious rites, their philosophical dogmas, their moral precepts, and their political maxims, were composed in verses which their pupils were obliged to commit to memory. Accordingly letters were unknown to the Caledonian Scots, till they learned them either from their southern neighbours, or from the Romans. The Irish, indeed, pretend to have letters of a very ancient date; but the Highlanders of the country in question make no claim to the use of that invention. Their bards, therefore, committed every thing to memory; and consequently the words of their language must have been faithfully preserved.

In order to exhibit the genius of the Celtic in as striking a light as the nature of our present design will permit, we shall lay before our readers a very short sketch or outline of the Gaelic or Caledonian dialect as it now stands; which, we trust, will go a great way to convince them that the latter is the genuine offspring of the other. In doing this we shall borrow many hints from the work of a gentleman[1] whose learning seems to have equalled his zeal for his native language, which, in compliance with the modern practice, we shall for the future distinguish by the name of Gaelic.

Structure of the Gaelic.

The Gaelic, then, is not as far as we know derived from any other language, being obviously reducible to its own roots. Its combinations are formed of simple words of a known signification; and these words are resolvable into the simplest combinations of vowels and consonants, and even into simple sounds. In such a language we may expect that some traces will be found of the ideas and notions of mankind living in a state of primitive simplicity; and if so, a monument is still preserved of the original manners of the Celtic race whilst as yet under the guidance of simple nature, without any artificial restraint or control.

The sudden sensations of heat and cold, and bodily pain, are expressed by articulate sounds, which, however, are not used in this language to denote heat, cold, or bodily pain. A sudden sensation of heat is denoted by an articulate exclamation *hait;* of cold, by *id;* of bodily pain, by *oich.* All these sounds may be called *interjections,* being parts of speech which discover that the mind is affected by some passion. Few of the improved languages of Europe present so great a variety of sounds which instantaneously convey notice of a particular passion, of bodily pain or mental feeling.

The pronouns *he* and *she* are expressed by the simple sounds *e* and *i,* and these again are the marks of the masculine and feminine genders; for the neuter gender is quite unknown in the Gaelic. The compositions of rude and barbarous ages are universally found to approach to the style and numbers of poetry; and this too is a distinguishing character of the Gaelic. The means of subsistence must always be the principal concern of an uncultivated people. Accordingly *ed* or *eid* is used upon the discovery of any animal of prey or game, and is meant to give notice to the hunting companion to be in readiness to seize the animal; and hence *edo* to eat in Latin, *ed* in Irish, signifying cattle, and *edal* in Scotch, literally signifying the offspring or generation of cattle. *Coed* or *cued,* a share or portion of any subject of property, is literally common food; *faœd,* hunting, literally gathering of food; *edra,* the time of the morning when cattle are brought home from pasture to be milked, literally meal-time. These are words importing the simplicity of a primitive state, and are common in the Gaelic idiom. Traces of imitative language may also be found in all countries. The word used for *cow* in the Gaelic language is *bo,* plainly in imitation of the lowing of that animal.

Excellen of Gaeli compoun

In joining together original roots in the progress of improving language and rendering it more copious, its combinations discover an admirable justness and precision of thought, which one would scarcely have expected to find in an uncultivated dialect. Upon examination, however, it will be discovered that the Gaelic language, in its combinations of words, specifies with accuracy the known qualities, and expresses with precision the nature and properties which were attributed to the object denominated. *An,* for instance, appears to have been a word of frequent use in this language, and seems to have been originally a name applied indefinitely to any object. According to Bullet, it was employed to signify a planet; and hence the *sun* had the name of *grian,* which is a compound of *gri,* hot, and *an* a planet. *Re* signifies originally and radically division. The changes of the moon and the variety of her phases were early employed to indicate the divisions of time. The present name for the *moon* is *geulach,* a word derived from her whiteness of colour. To these we might add a vast number more, the signification of which precisely indicates their shape, colour, effects, or other accidents. Many of these would be found exactly similar to Greek and Latin words of the same sound and signification. In order to satisfy our curious readers, we shall annex a few, though some of them may perhaps be questionable.

The *Venus* of the Latins is supposed to be a compound of *ben* and *jus,* which literally signify the first woman, the letter *b* in Gaelic being softened into *v.* Εδαρ and εἴδαρ signify food. These words are compounded of the Gaelic words *ed* or *eid* and *ar,* the former simply denoting *food,* and the latter *ploughed land;* and they are the roots of the Greek and Latin words ἐδω, *edo;* ἀροω, *aro.* Εδρα, which signifies a seat, has also an evident reference to food. It is compounded of two Gaelic words *ed* and *ira,* which literally signify meal-time. Εδνα, which signifies the presents that a bridegroom made to his bride, is a compound of two Gaelic words *ed* and *na* or *nuah,* literally signifying raw food. From *ar* there are many Greek derivatives. Αρουρα signifies ploughed land, and also a crop of corn; and ἀρτος means bread. In Gaelic *a crop of corn* and *bread* are expressed by *arbhar,* which is commonly pronounced *arar* and *aran,* both being equally derivatives of the root *ar.* So the Greek and Latin words ἀροτος, *arabilis,* arable; ἀροτρον, *aratrum,* a plough; ἀροτηρ, *arator,* a ploughman; and many others, are evidently derived from the same source. From this coincidence, however, we are not prepared to maintain that either the Greek or the Latin languages were derived from the Gaelic; we are rather inclined to think that these are remains of a primeval tongue, which are still retained in all the three, and we produce them upon the present occasion as presumptions that the Gaelic is an original, underived language, and of course the most pure and unadulterated relic of the Celtic now existing.[2]

Copiousness and antiquity of the Celti

When the Celtic language was generally spoken throughout Europe, it seems to have been amazingly copious. By consulting Bullet's *Mémoires,* it will be seen that its names for the common and various objects of nature were very numerous. The words denoting water, river, wood, forest, mountain, lake, and other natural objects, were most precisely accommodated to specify each modification and variety, with such peculiar exactness that even the Greek, with all its boasted idiomatical precision and copiousness, has not been able to equal it. The appearances which diversify the visible face of animated nature, arrest the attention of men in an uncultivated state. Unaccustomed to thought and abstract reasoning, their minds expand and exercise their powers upon sensible objects, and of course mark every minute and almost imperceptible distinction with an accuracy which to us seems impossible. It therefore appears to us, that the Celtic formed one of the dialects of the primitive language; that anciently it overspread by far the greatest part of Europe; and that the Gaelic now spoken in the northern parts of Scotland and the adjacent islands is the purest and most unmixed relic of that language anywhere existing at the present time.

---

[1] The writer here referred to is Mr. Grant, whose *Essays* contain much curious information on the subject of which this section treats.

[2] If our readers should incline to know more of this subject, they may consult Pezron's *Origin of Ancient Nations,* Bullet's *Mémoires de la Langue Celtique,* Parson's *Rem. of Japhet,* and Gebelin's *Monde Primitif.*

We would willingly refer our readers to some well arranged Gaelic grammar; but in point of fact we know of none which deserves particular recommendation. That by Dr. Stewart, however, is the best of its class, and considering the difficulty of the undertaking, it must be regarded as a creditable performance, notwithstanding its deficiency in philosophical precision, and simplicity of arrangement. The Dictionary of the Highland Society, in two volumes quarto, and that by Dr. Armstrong, in one volume of the same size, though neither of them, perhaps, what could in all respects be desired, must, nevertheless, afford great facilities to the student of Gaelic.[1] These works, together with the excellent translation of both the Old and New Testaments into Gaelic, which was long a great desideratum amongst the Highlanders, many of whom are still unacquainted with English, will contribute to preserve their ancient tongue, and to disseminate the knowledge of the truth amongst the natives of the mountains.

Every assistance towards acquiring the knowledge of a language which was once diffused over a great part of Europe, is certainly an acceptable present to the public. The antiquary, who is desirous of tracing the affinity of languages, and who wishes to mark the migrations of different races, ought to apply himself to the study of its remaining branches; and, if we are not mistaken, he will soon be convinced, that they all breathe a spirit congenial to the manners and sentiments of people who are just entering upon the first stage of improvement and civilization.

rigin of e words *aul* and *al.*

Perhaps it may be expected, that, before we conclude this short sketch of the Celtic language, we should give some account of the origin of the words *Gaul* and *Gal*, the two names by which this people were distinguished by the Greeks and Romans. Mr. Macpherson imagines, that the appellation of *Celt* is an adjective derived from *Gael*, the aboriginal name of the inhabitants of ancient Gaul. For our part, we can see no connection whatever between *Gael* and *Kelt*, nor do we think that the latter is an adjective. We believe that this people called themselves *Cael* and not *Gael;* and there is little room for doubt that *Caledonia*, that is, *Caldon* or *Cal-dun*, was an ancient name of the mountainous parts of Scotland.

Though many different opinions have been advanced respecting the etymology of this word, we imagine that none is so probable as that which supposes that it is compounded of the two Celtic words, *Cal* or *Kal*, that is, Gal or Gaul, and *dun*, which signifies a hill or mountain. Upon this ground, the *Caledones* will import the Gauls of the mountains, or which is the same, the Highland Gauls. The Irish and Highlanders reciprocally denominate themselves *Cael, Gael,* or *Gauls.* They also distinguish themselves, as the Welsh originally did, and as the Welsh distinguish them both at present, by the appellation of *Guidhill, Guethel,* and *Gathel.* The intermediate *th*, they say, is left quiescent in the pronunciation, as it is in many words of the British language, so that *Gathel* would immediately be formed into *Gael;* and Gathel is actually sounded like *Gael* both by the Irish and by the Highlanders. The appellation of *Gathel*, therefore, say they, was originally the same with *Gael*, and the parent of it. The quiescent letters in the British are frequently transferred from the middle to the conclusion of the word; by which means *Gathel* is changed into *Galath, Galat, Galt,* and *Celt.* It is true, that the *Gael* of the continent are universally denominated *Galatæ* and *Celtæ* by the Grecians, and *Gallt* and *Gallta* by the Irish. The appellations, therefore, of *Gathel-i, Gall-i, Gallat-æ, Calet-es, An-calit-es,* and *Celt-æ,* are all one and the same denomination, only varied by the astonishing ductility of the Celtic, and disguised by the alterations ever incident to a language which has for ages been merely oral.[2]

It may perhaps appear presumptuous in us to differ from two such respectable authorities as Macpherson and Whitaker; but we must, nevertheless, acknowledge, that neither the one nor the other appears to us to be well founded in his views. Besides, they convey no idea of the signification of the words, though in the Celtic language these must have been significant. The name *Cael*, the same with *Gal*, was probably given them in the East from the Greek καλ, which in many oriental languages denotes *fair;* and γαλατια may be easily derived from γαλ or γαλαθ, *Gal* or *Galath;* a denomination which might be given them by their neighbours, in allusion to their fair complexion.

§ 2.—*Of the Gothic Language.*

Ancient Gothic.

The Celtic and Gothic languages at one period divided Europe between them. Both were of equal antiquity, both originated in Asia, and both were dialects of the original language of mankind. The Celtic, however, was first imported into Europe. The Gauls or Celts had penetrated farthest towards the west, a circumstance which plainly intimates the priority of their arrival. In the population of countries, it may be held as a maxim, that the colonies who first emigrated were generally impelled by succeeding emigrants; and that consequently the most early were pushed forward to the parts most distant. The Celts, then, having overspread the most western parts of Europe, must have been the first who established themselves in those regions.

The same with the language of the Thracians.

The Goths and Getæ were the same race of people, according to Procopius[3]; and Strabo informs us, that they spoke the same language with the Thracians, from whose confines they had spread themselves northward as far as the western banks of the Danube.[4] Vopiscus, in the History of Probus, tells us, that this emperor obliged "the Thracians, and all the Getic tribes, either to surrender or accept of his friendship," an expression which indicates, that the Thracians and the Getic tribes were deemed the same race of people.[5] From this deduction then, it is clear, that the Getæ and Thracians were brethren, and spoke the same language;—and that their laws, manners, customs, and religious tenets, were the same, might easily be shewn, were this the proper place for such an inquiry. The Thracian language, as might be demonstrated from names of persons, offices, places, and customs, amongst the people who spoke it, was nearly related to the Chaldaic and other oriental languages.

---

[1] The Dictionary of the Highland Society is executed with great ability to the extent of between two-thirds and three-fourths of the whole; but the subsequent portion betrays that it had fallen into inferior hands; and some of the Latin definitions are such as can scarcely fail to astonish the accurate scholars of the Continent. The death of Mr. Maclachlan, of Aberdeen, the original conductor, proved a great calamity to the work. Equally eminent as a classical, oriental, and Celtic scholar, and profoundly learned in philology, his place could not be supplied; and though occasional assistance was obtained from men equally conversant with Latin and with Celtic, such as the late Rev. Mr. Macdonald of Crieff, the elegant author of the *Phingaleis*, yet the master mind was removed, and the work suffered in consequence. Still, with all its acknowledged defects, it is a valuable present to the philologist as well as the scholar, and does honour to the liberal and patriotic spirit of the National Association under whose auspices it was brought out.

[2] We must caution our readers, however, not to confound *Gael* with *Gal* or *Gall*, which, in the Celtic, signifies a stranger.

[3] *De Bello Gothico*, lib. i. c. 2.

[4] Lib. ii. cap. 23.

[5] Lib. vii. p. 295; ibid. p. 305, Casaubon. From this passage it appears, that the Greeks were of opinion that the Getæ were Thracians. Pliny (*Nat. Hist.* lib. iv. cap. 11.) mentions a tribe of the Getæ called *Gaudæ*.

Origin of the Goths.

The Goths are thought to have been the descendants of Tiras, one of the sons of Japhet, and consequently must have preserved the speech of the Noachic family. The Gothic language abounds with Pahlavi, or old Persian words, which are no doubt remains of the primitive dialect of mankind. The Thracians peopled a considerable part of the northern coast of Asia Minor; and consequently we meet with many names of cities, mountains, rivers, and other objects in those parts, exactly corresponding with many names in Europe, evidently imposed by our Gothic progenitors. These any person tolerably acquainted with the remains of the Gothic language, will be able to trace with little difficulty.

We learn from Herodotus,[1] that Darius in his expedition against the wandering Scythians who lived on the other side of the Ister or Danube, subdued in his progress the Getæ; and in the same passage the historian informs us, that this people held the immortality of the human soul, and were the bravest and justest of all the Thracians. After this period, we find them mentioned familiarly by almost every Greek writer; for, in the comedies of that nation, Geta is a common name for a slave. The Getæ then occupied all that large tract of country which extended from the confines of Thrace to the banks of the Danube; they were a brave and virtuous people, who spoke the same language as the Thracians, with whom they are often confounded both by the Greek and the Roman historians. But the name of Goths is not by any means so ancient. It was utterly unknown to the ancient Greeks and Romans. The first time that the name Goth is mentioned is in the reign of the emperor Decius, about the year of Christ 250. About that period they had burst out of Getia, and rushing like a torrent into the empire, laid waste every thing with fire and sword. The name of their leader or king was *Cneva*; and Decius, in endeavouring to expel them from Thrace, was vanquished and slain.

After this irruption, we find them frequently mentioned by the Latin authors under the name of *Getæ* or *Gothi*, though the Greeks generally denominate them *Scythæ*. Torfæus tells us, that *get* and *got* are in reality the same word, and according to him, anciently denoted a soldier.[2] *Got* in Icelandic signifies a horse or horseman, and *gata* a wanderer; and this was perhaps the import of the term *Geta*, because the *Getæ* were originally an unsettled and vagrant people. As nations generally assume to themselves some high and auspicious denomination, it may be presumed that the Goths did the same. We may therefore be satisfied, that the Getæ assumed the Icelandic name above mentioned as their national one; or perhaps, that, notwithstanding their Greek denomination, they from the beginning called themselves *Gots* or *Goths*.

Primary seat of the Goths.

The original seat of the Goths was the country now called Little Tartary, into which they had extended themselves from the frontiers of Thrace. This country was called Little Scythia by the Greek writers; and it was the station whence those innumerable swarms advanced, which, in conjunction with the Alani and other barbarous tribes, at length overran and subverted the western empire. One part of the Gothic nation was allowed by Constantine to settle in Mœsia. Before the year 420 of our era, most of the Gothic nations who had settled within the limits of the Roman empire had been converted to the Christian faith; but, unhappily, the greater part of the apostles by whom they had been proselytized were Arians; and this proved fatal to many of the orthodox Christians, whom the Arian Goths persecuted with unrelenting cruelty.

Remains of genuine Gothic.

About the year 367, Ulphilas, bishop of the Mœsian Goths, translated the New Testament into the language of that people. The remains of this translation furnish a genuine, and at the same time a venerable, monument of the ancient Gothic dialect. Of that valuable translation no more is now extant than the four Gospels, and another fragment containing part of the epistle to the Romans. The Gospels have been repeatedly published since the first edition by Junius which appeared in the year 1665. There have also been discovered other fragments of the Gothic language which the curious reader may find in Lye's notes to his edition of the Gothic Gospels. The fragment of the Epistle to the Romans was discovered in the library at Wolfenbuttle, and published by Knitel arch-deacon of Wolfenbuttle, as has been fully explained in another article of this work (Palimpsests). Prior to the age of Ulphilas, the Goths were ignorant of the use of alphabetical characters. But that bishop fabricated for them an alphabet, which consists of a medley of Greek and Roman letters, though rather inclining to the former.

Gothic alphabet.

The Gothic alphabet is composed of twenty-five letters. Junius has carefully analyzed these letters, and pointed out their powers and sounds, in the alphabet prefixed to his *Glossarium Gothicum*. They were long retained in all the European languages which acknowledged the Gothic as the source whence they had been derived, and which will be enumerated in the sequel.

Origin of the Gothic language.

What kind of language the ancient Gothic really was, may be inferred from the fragments above mentioned; but in what respects it agrees with the oriental tongues, or differs from them, is not easy to ascertain with precision. In the section on the Greek, we have observed that a considerable part of that language must have been derived from the Thracian, which, according to Strabo, was the same with the Getic or Gothic; and we are convinced that the Thracian language will, on comparison, be found analogous to the Chaldaic or Syriac. The German, which is a genuine descendant of the Gothic, is full of Persian words; and the old Persian or Pahlavi appears to have been a dialect of the Chaldaic. Junius, in his treatise on the Gothic alphabet, remarks that a very considerable part of the Gothic language is borrowed from the most ancient Greek; but, perhaps, it would have been nearer the truth, if he had reversed this observation, and stated that the ancient Greek was in a great measure derived from the Gothic.

The learned Ihre in his *Glossarium Suio-Gothicum*, and Wachter in his excellent German and Latin Dictionary, remark the coincidence of Gothic and German words with oriental nouns of a similar sound and the same signification. In the old Saxon, which is another ramification from the Gothic stem, numberless terms of the very same complexion appear. Hence it appears that the Gothic in its original and unmixed state as spoken by the ancient Getæ, was a dialect of the primeval language, which the sons of Tiras had brought with them from the plains of Shinar, Armenia, or some other region, where "the world's grey fathers" had fixed their residence.

The Thracian tribes, in all probability, first took possession of those parts of Asia Minor which stretch towards the east; and thence crossing the Hellespont, they spread themselves northward. Strabo supposes that they first settled in the regions to the north of this strait, and thence transported numerous colonies into Asia Minor. The reverse was probably the case; but be this as it may, it is universally agreed, that both sides of the Hellespont were at one time peopled with Thracians.

In Asia Minor we meet with the city Perga, which, throwing away the *a*, is *Perg*. But in every tongue descended from the Gothic, the word *Berg* signifies a rock, and metaphorically a town or burgh, because towns were originally built upon rocks for the sake of defence. Hence likewise *Pergamus*, the fort or citadel of Troy. *Beira*, in Thracian, signified a city; whilst the Chaldaic and Hebrew word *Beer* imports a well, and is possibly the original of the Gothic word *beer*, ale. In ancient times, especially in the East, it was customary to build cities in the neighbourhood of fountains. The ancients called the Phrygians Βρυγες, *Bryges*, or *Bruges*, a name which is obviously of Gothic origin. *Dyndymus*, the name of a city sacred to Cybele, is compounded of two Gothic words *dun* and *dum*, both signifying a height or an eminence, and hence a town or an inclosure. The word *tros* seems to be the Gothic word *trosh*, signifying brave, valiant. The words *fader*, *mader*, *dochter*, *bruder*, are so obviously Persian, that almost every etymologist has assigned them to that language.

---

[1] Lib. iv. *passim*.

[2] *History of Norway*, lib. i.

Many futile etymologies have been given of the sacred name *God*, which is in reality the Persian word *Choda*, commonly applied by them to their Hormuzd or Oromasdes. The Persian *bad* or *bod* signifies a city; and the same word in Gothic imports a house, a mansion, an abode. *Band*, in Persian, is a strait place; in Gothic, it signifies to bend. *Heim* or *ham*, a house, is generally known to be of Persian origin. Much critical skill has been displayed in tracing the etymology of the Scotch and old English word *Yule* or Christmas. *Yule*, derived from *iul*, was a festival in honour of the sun, which was originally celebrated at the winter solstice. *Wick* or *wich* is a Gothic term still preserved in many names of towns; it signifies a narrow corner, or small strip of land jutting into the sea, or into a lake or river; hence the Latin *vicus*, and Greek φοικος. In Spanish we have many old Gothic words, and amongst the rest *hijo*, a son, the same with the Greek ὑιος. In some places of Scotland we call any thing that is little, or small, *wee*, originally spelled *wi*, which if we mistake not, is formed from the very same word.

These examples we have thrown together, without any regard to order, being persuaded that almost every word of the language, which is truly Gothic, may with a little pains and judgment be traced to some oriental root or cognate term. We may observe in passing, that many Gothic nouns end in *a*, like the Chaldaic and Syriac; that their substantive verb very much resembles that of the Persian, Greek, and Latin; and that their active and auxiliary verb has furnished the common preterperfect tense of Greek verbs in the active voice. That verb is *haban*, but was originally *ha*, as the common people pronounce it at this day, especially in the north of Scotland, and amongst the Swedes, Danes, Norwegians, and Icelanders.

dern ects de- d from Gothic.

Leaving the inferior arrangements of this ancient language to grammarians and lexicographers, we shall now proceed to inquire what modern tongues have been derived from it as their source, and which of them makes the nearest approach to its simplicity and rusticity. We have already observed that the Goths, formerly Getæ, were possessed of a vast extent of country, reaching from the frontiers of Thrace to the banks of the Ister or Danube. We have also seen that a colony of them settled in Mœsia under Constantine II.; after which they spread themselves throughout Dacia, and thence passed into Germany. All these countries were situated in such a manner, that the progress of population was commensurate with the natural course of emigration. From Germany they extended themselves into Scandinavia, that is, Sweden, Denmark, and Norway. All the ancient Edda, Sagas, and Chronicles, shew that the Goths arrived in Scandinavia by this route, without, however, fixing the era of that event with any tolerable degree of accuracy. By the Germans, the ancients most probably understood all the nations eastward, westward, and northward, reaching from the Danube on the south to the extremity of Scandinavia in the northern ocean, and from the Rhine and German ocean on the west, to the river Chronus or Niemen on the east. But all the nations included within these limits spoke one or other of the Gothic dialects, some approaching nearer, and others deviating farther from, the parent language.

The Francic is plainly a dialect of the Teutonic, Tudesque, or old German; and the Gospels of Ulphilas bear such a resemblance to the Francic, fragments of which are preserved in the early French historians, that some learned men have pronounced these gospels part of an old Francic version; but others of equal respectability have refuted this opinion, both from history and a comparison of the dialects. Schilter has given us several specimens of the Tudesque or old German in the seventh century, which evidently prove that the Gothic of Ulphilas is the same language; and Wachter's learned glossary of the ancient German confirms the position of Schilter. Ihre, after hesitating whether the Gospels of Ulphilas bear most resemblance to the German or Scandinavian dialect of the Gothic, declares at last in favour of the former. The Anglo-Saxon is also known to be a venerable dialect of the Tudesque; and is so intimately connected with the gospels, that some valuable works on this subject are wholly built upon that supposition.

The Icelandic is the most ancient relic of the Scandinavian. It begins with Arius Frode in the eleventh century, and is a dialect of the German. The remains we have of it are more modern by four centuries than those of the German; and they are also more polished. The words are shortened, not only because they are more modern than the German, but because the Icelandic was polished by a long succession of poets and historians almost equal to that which does so much honour to Greece and Rome. Hence the Icelandic, being a more polished language than the German, has less affinity with the parent Gothic. The Swedish is more nearly related to the Icelandic than either the Danish or Norwegian. That the Swedish is the daughter of the Gothic, has been very clearly shewn by Ihre, in his *Glossarium Suio-Gothicum*. There is, therefore, no manner of doubt as to the identity of the Gothic, preserved in Ulphilas and other ancient remains, with the German and Scandinavian tongue. The modern German, resembles the Gothic Gospels more than the present Danish, Norwegian, or Swedish, and has certainly more ancient *stamina*. Its resemblance to the Asiatic tongues, in harshness and inflexible thickness of sound, is likewise very apparent.[1]

Busbequius shews that the peasantry of Crim Tartary, who are remains of the ancient Goths, speak a language almost German. These peasants were no doubt descendants of the ancient Goths, who remained in their native country after the others had emigrated. It is therefore apparent from the whole of this investigation, that the Gothic was introduced into Europe from the East, and that it is probably a dialect of the language originally spoken by the founders of human society.

§ 3.—*Of the Sclavonian Language.*

Sclavonic language.

There is another language which pervades a considerable part of Europe, and which, like the Gothic, seems to have originated in the East. The language we allude to is the Sclavonic or rather Slavonic, which prevails to a great extent in the eastern parts of this division of the globe. It is spoken by the Dalmatians, by the inhabitants of the Danubian provinces, by the Poles, Bohemians, and Russians. The word *slab*, that is, slave, whence the French word *esclave*, and our word *slave*, signifies noble, illustrious; but because in the lower ages of the Roman empire, vast multitudes of this people were spread over all Europe in the quality of slaves, that word came to denote the servile tribe by way of distinction, in the same manner as the words *Geta*, *Davus*, and *Syrus*, did amongst the Greeks at a more early period.

---

[1] It is a pity that the learned author of this treatise did not pursue the ingenious and profound thought which here suggested itself to his mind. If he had done so, he would, beyond all question, have anticipated the continental philologists in the discovery of a new principle of classifying languages, and more particularly in separating from the mass that great family which has been so aptly denominated Indo-European. But all the elements of the new classification are to be found in the present treatise. The affinity of the Greek and the Gothic, the parentage of the old German, and the oriental origin of both, are as distinctly intimated as in any of the works of Klaproth or his contemporaries; and if the author had known Sanscrit, he would, at the first glance, have anticipated the most important discovery which has rewarded the philological research of the nineteenth century.

Slavi.

The Slavi dwelt originally upon the banks of the Borysthenes, now called the Dnieper or Nieper. They were one of the tribes of the European Sarmatians, who in ancient times inhabited an immense tract of country, bounded on the west by the Vistula, and on the south-east by the Euxine or Black Sea, the Bosphorus Cimmerius, the Palus Mæotis, and the Tanais or Don, which divides Europe from Asia. In this vast tract of country, there dwelt aboriginally many considerable tribes. To enumerate these, however, would not much edify our readers; and we shall only inform them, that amongst the Sarmatian clans were the Roxolani, now the Russians, and likewise the Slavi, who dwelt near the Borysthenes. The Slavi gradually advanced towards the Danube; and in the reign of Justinian having passed that river, they made themselves masters of that portion of Illyricum which lies between the Drave and the Save, and is to this day called *Sclavonia*. By degrees these barbarians overran Dalmatia, Liburnia, the western parts of Macedonia, and Epirus; and on the east they extended their conquests to the western bank of the Danube, where that river falls into the Euxine. In all these countries the Sclavonian was deeply impregnated with the Greek; which indeed was a matter of course, as the barbarian invaders settled in these regions, and mingled with the aborigines, who spoke a corrupt dialect of the Greek language.

The Poles, &c.

The Poles are the genuine descendants of the ancient Sarmatians,[1] and consequently speak a dialect of the language of that race, though much adulterated with Latin words, in consequence of the attachment this people have long professed to the Roman tongue. The Silesians and Bohemians have corrupted their dialects in a similar manner. In these countries, then, we are not to search for the genuine remains of the ancient Sarmatian.

Russians.

The modern Russians, formerly called Rhoxani or Roxolani, are the posterity of the Sarmatæ, and constitute a branch of the Slavi. They inhabit a part of the country which that people possessed before they fell into the Roman provinces; they also speak the same language, and wear the very same dress. If then the Slavi are Sarmatæ, the Russians must of course be the descendants of the same people. They were long a sequestered people, and consequently altogether unconnected with the other nations of Europe. They were unacquainted with commerce, inhospitable to strangers, tenacious of ancient usages, averse to improvements of every kind, wonderfully proud of their imaginary importance, and, in a word, a race of men just one degree above absolute barbarism. A people of this character are, for the most part, enemies to innovations; and if we may believe the Russian historians, no nation was ever more averse to changes than their own. From the ninth century, at which era they embraced Christianity, it does not appear that they moved one step forward towards civilization, until Peter the Great, little more than a century ago, compelled them by his despotic authority to adopt the manners and customs of their more polished neighbours.

We may then conclude, that, during the period in question, the Russians made as little change in their language as they appear to have done in their dress, habits, and manner of living. Whatever language they spoke in the ninth century, the same they employed at the beginning of the eighteenth. They were, indeed, according to Appian, once conquered by Diophantus, a general of Mithridates; but that conquest was for a moment only. They were likewise invaded, and their country was overrun, by the great Timur or Tamerlane; but this invasion proved like a torrent from the mountains, which spreads devastation far and wide whilst it rages, but makes little alteration on the face of the country. We find, likewise, that upon some occasions they made incursions upon the frontiers of the Roman empire; but we hear of no permanent settlements formed by them in the countries which they overran. Upon the whole, the Russians, with respect to their language, were in nearly the same predicament with the Highlanders and Islanders of Scotland, who, according to the general opinion, have preserved the Celtic dialect pure and entire, solely from their never having mingled with foreigners.

The Russian genuine Sclavonic.

From this deduction we may infer two things; first, that the Russian language is the genuine Sclavonian; and, secondly, that the latter is the same, or nearly the same, with the ancient Sarmatian. In the Russian, there are found a great number of words resembling, both in sound and signification, the old simple roots of the Greek; its grammatical genius is nearly the same; and we are informed by the very best authority, that there exists in this language a translation of Epictetus, in which there are whole pages, both in the original and the translation, without one single transposition. M. Lévêque, who published a translation of a history of Russia, was so entirely convinced of the strict analogy between the ancient Greek and the modern Russian, that he became positive as to the former having been derived from the latter. M. Fréret, a very learned French academician, also adopted the same opinion. We are persuaded, however, that this opinion is ill-founded, and rather conceive, that these coincidences arise from the relics of the primitive language of mankind, vestiges of which, we believe, are to be found almost in every tongue now extant.

It is, however, we admit, exceedingly difficult to render a reason for the syntaxical analogy of the two languages, without admitting the truth of the one or other of the hypotheses mentioned. We have examined with some care a goodly number of Russian words, and compared them with Greek words of the same signification; but we have not found such a resemblance as we consider necessary to support the position above advanced. We have indeed discovered a very strong resemblance between the former and many oriental words, especially Hebrew, Chaldaic, and old Persian, of which we could produce several instances, did the nature of our present inquiry admit such a deviation. Every body knows that the Sarmatians were divided into two great nations, the Asiatic and the European. The former extended very far to the eastward, behind the mountain Caucasus, the northern shore of the Euxine Sea, and probably derived their language from the original form of speech long before the Greek language existed. But this, in comparison with the Hebrew, Phœnician, Egyptian, Arabian, and Chaldean, was but of yesterday. The Greek, most learned men are now convinced, was a late composition of many different dialects, incorporated with the jargon of the aboriginal Ionim or Greeks. The Sarmatian, on the contrary, was the language of a great and populous nation, civilized, in all appearance, long before the Greeks began to emerge from a state of barbarism. We are, therefore, by no means disposed to allow, either that the Greek is derived from the Russian, or that the Russian is derived from the Greek. We believe there is just the same reason for this conclusion, that the Abbé Pezron and M. Gebelin pretend to have discovered, for supporting their position that the Greek is derived from the Celtic. Certain it is, that the resemblance amongst the oriental languages, of which we conceive the Sarmatian to have been one, is so palpable, that any person of moderate capacity who is perfectly master of one, will find but little difficulty in acquiring any other. If, therefore, the coincidence between the Greek and Russian should actually exist, we think this circumstance will not authenticate the supposition, that either of the two is derived from the other.

---

[1] This appears by their character, their laws, their manners, their form of government, their military equipage, their impetuosity, their aristocratic splendour.

In the course of this argument, our readers will be pleased to observe, that we all along suppose, that the Sclavonian, of which we think the Russian is the most genuine remain, is the same with the old Sarmatian. We shall now take the liberty to hazard a conjecture with respect to the syntaxical coincidence of that language with the Greek; for we acknowledge that we are not so profoundly versed in the Russian dialect of the Sclavonian as to pretend to pronounce a definitive sentence.

Syntactical coincidence between this language and the Greek.

As the Russians were a generation of savages, there is no probability that they were acquainted with the use of letters and alphabetical writing until they acquired that art by intercourse with their neighbours. It is certain that few nations had made less proficiency in the fine arts; and there is little appearance of their having learned this art previously to their conversion to Christianity. It appears, indeed, that the Slavi, who settled in Dalmatia, Illyria, and Liburnia, had no alphabetical characters till these were furnished with them by St. Jerome. The Servian character, which very nearly resembles the Greek, was invented by St. Cyril; and on this account the language written in that character is denominated *Chiurilizza.* But these Sclavonic tribes knew nothing of alphabetical writing prior to the era of their conversion; and the Mœsian Goths were in the same condition till their bishop Ulphilas fabricated for them a set of letters. If, then, the Slavi and Goths, who resided in the neighbourhood of the Greeks and Romans, had not learned alphabetical writing prior to the era of their conversion to Christianity, it follows, *a fortiori*, that the Russians, who lived at a great distance from these nations, knew nothing of this useful art antecedent to the period of their embracing the Christian faith.

The Russians pretend that they were converted by St. Andrew; but this is known to be a fable. Christianity was first introduced amongst them in the reign of the grand duke Woladimir, who having married the daughter of the Greek emperor, Basilius, became her convert about the year 989. About this period they were taught the knowledge of letters by the Grecian missionaries, who were employed in teaching them the elements of the Christian doctrines. Their alphabet consists of thirty-one letters, with a few obsolete additional ones; and these characters resemble so exactly those of the Greeks that there can be no doubt of their being copied from them. It is true, the shape of several has been somewhat altered, and a few barbarous characters have been intermingled. The Russian liturgy, as every body knows, was copied from that of the Greeks; and the best specimen of the old Russian is to be found in the church offices for Easter, which are in the very words of Chrysostom, who is called by his name *Zlato ustii,* or golden-mouthed. The power of the clergy in Russia was excessive; and their influence was, no doubt, proportioned to their power. The first race of clergy in that country were undoubtedly Greeks, because we know how active and industrious that people were in propagating their language as well as their religion. The offices of religion might at first be written and pronounced in the Greek language, but it would soon be found expedient to have them translated into Russian; and the persons employed in this work must have been Greeks, who understood both languages.

As it is confessedly impossible that a people so dull and inattentive as the Russians originally were, could ever have fabricated a language so artificially constructed as their present dialect; and as it is obvious, that, until Christianity was introduced amongst them by the Greeks, they could have no correspondence with that people; it must appear surprising by what means their language came to be fashioned so exactly according to the Greek model. We have observed above, that the Russian letters must have been invented and introduced into that country by the Greek missionaries; and we think it probable, that these apostles, at the same time that they taught them a new religion, likewise introduced a change into the idiom of their language. The influence of these ghostly teachers over a nation of savages must have been almost boundless, the force of their precepts and example almost uncontrollable. But if the rude and savage converts accepted a new religion from the hands of Grecian apostles, they might with equal submission adopt improvements in their language. Such of the natives as were admitted to the sacerdotal function must have learned the Greek language, in order to qualify them for performing the offices of their religion; and a predilection for that language would be the immediate consequence. Hence the natives, who had been admitted into holy orders, would co-operate with their Grecian masters in improving the dialect of the country, which, prior to the period above mentioned, must have greatly deviated from the original standard of the Sarmatian language.

Upon this occasion the Grecian apostles, in conjunction with their Russian disciples, probably reduced the language of the country to a resemblance with the idiom of the Greek. They retained the radical terms as they found them, but by a variety of flections, conjugations, derivations, compositions, and other modifications, transformed them into the Grecian air and apparel. They must have begun with the offices of the church; and amongst a nation of newly converted savages, the language of the religion they had been induced to adopt, would quickly obtain a very extensive circulation. When the Grecian garniture was introduced into the church, the laity would in process of time assume a similar dress. The fabric of the Greek declensions, conjugations, and inflections, might be grafted upon Russian stocks without affecting the radical parts of the language. If the dialect in question, like most others of a very ancient date, laboured under a penury of words, such a device would contribute exceedingly to supply that defect. By this expedient the Greek language itself had been enlarged from about three hundred radical terms to the prodigious number of words of which it now consists.

The Latin language, in its original constitution, differed widely from the Greek; but notwithstanding this incongruity, the improvers of the former have pressed it into a very strict agreement with the latter. This, we think, was a still more difficult task, because the genius of the Latin differs in a much greater degree than that of the Russian does from the genius of the Greek. We know that the Gothic language and all its descendants are, in their essential character, much more in unison with the Greek than they are with the Latin. The Spanish, Italian, and French, have cudgelled many of their Gothic, Teutonic, and Celtic verbs, into a kind of conjugations, imitating or rather aping those of the Latin. The Persians have also formed most elegant and energetic declensions and conjugations, upon inflexible roots borrowed from the Pahlavi and Deree, and even from Tartarian originals.

Upon the grounds above mentioned we now take the liberty to hazard the following conjectures, which we cheerfully submit to the cognizance of more enlightened philologists, viz. 1. That the Sarmatian was a dialect of the original language of mankind; 2. That the Sclavonian was a dialect of the Sarmatian; 3. That the Russian is the most genuine and unsophisticated relict of the Sclavonian and Sarmatian; 4. That the Russians had no alphabetical characters prior to the era of the introduction of Christianity, that is, towards the end of the tenth century; 5. That they were converted by Grecian missionaries; 6. That these missionaries formed their present letters from those of Greece, and, in conjunction with the more enlightened natives, reduced the original and unimproved Russian to its present resemblance to the Grecian standard.

Russian parts of speech.

The Russian language, like most others, contains eight parts of speech. Its nouns have three genders, masculine, feminine, and neuter; and it has also a common gender for nouns, intimating both sexes. It has only two numbers, singular and plural. Its cases are seven, nominative, genitive, dative, accusative, vocative, instrumental, and prepositive. These cases, however, are not formed by varying the termination, as in Greek and Latin, but generally by placing a vowel after the word, as, we imagine, was the original practice of the Greeks. Thus in Russian, *ρυκ*, *ruk*, the hand; nominative, *ρυκ-α*, the hand; genitive, *ρυκ*-Nʼ of the hand.[1] Nouns substantive are reduced to four declensions, but adjectives constitute a fifth. The latter agree with their substantives in case, gender, and number; and they have three degrees of comparison, as is common in other languages, viz. the positive, comparative, and superlative. The comparative is formed from the feminine of the nominative singular of the positive, by changing *a* into *te*, that is, *aie* in English; and the superlative is formed by prefixing *πρε*, *pre*, before the positive. These rules are general; with regard to the exceptions, recourse must be had to a Russian grammar.

The numeral adjectives in Russian have like the rest three genders, and they are declined accordingly. Their pronouns have nothing peculiar, being divided and arranged in the same manner as in other languages. Verbs in the Russian language are comprehended under two conjugations. The moods are only three; the indicative, the imperative, and the infinitive. The subjunctive is formed by placing a particle before the indicative, and its tenses are eight in number; the present, the imperfect, the preterite simple, the preterite compound, the pluperfect, the future indeterminate, the future simple, the future compound. The verbs have their numbers and persons as in other languages. To enter into a detail of the manner of conjugating Russian verbs would neither be consistent with our plan, nor of much consequence to our readers. The remaining parts of speech differ in nothing from those of other languages. The syntax of Russian nearly resembles that of the Greek and Latin. But all these accidents must be learned from a grammar of the language. We could have wished to be able to gratify our readers with a more authentic account of the origin of the Sclavonic language; but this we find impossible, owing to the want of materials relating to the state of the ancient Sarmatæ. Towards the era of the subversion of the western empire, the nations who inhabited the countries in question were so blended and confounded with each other, and with Huns and other Scythian or Tartar tribes, that the most acute antiquarian would find it impossible to investigate their respective dialects, or even to fix their original residence and extraction.

Phœnician and Chaldean words in Russian.

We have selected the Russian as the most genuine branch of the old Sclavonic, and to this preference we were determined by the reasons above mentioned. We are not sufficiently acquainted with the idiom of the Russian language to be able to compare it with those of the East; but were such a comparison made we are persuaded that the radical materials of which it is composed would be found to have been of oriental origin. The word *Tsar*, for example, is probably the Phœnician and Chaldean *Sar*, or *Zar*, a prince, or grandee. Diodorus Siculus calls the queen of the Massagetæ, who, according to Ctesias, cut off the head of Cyrus, *Zarina;* which still continues to be the national title of the empress of all the Russias. Herodotus calls the same princess *Tomyris*, which is the very name of the celebrated Timur or Tamerlane the conqueror of Asia. The former seems to have been the title, and the latter the proper name, of the queen of the Massagetæ. In the old Persian or Pahlavi, the word *gard* signifies a city. In Russian, *gorod* or *grad* intimates the very same idea; and hence Constantinople in old Russian is called *Tsargrad* or *Tsargorod*. These are only a few specimens; but skilful etymologists might, we believe, discover a great number more.

The Sclavonian language is spoken in Epirus, in the western part of Macedonia, in Bosnia, Servia, Bulgaria, in part of Thrace, in Dalmatia, and Croatia, in Poland, Bohemia, Russia, and Mingrelia, and hence it is frequently used in the seraglio at Constantinople. Many of the great men of Turkey understand it, and frequently use it; and all the janizaries who had been stationed in garrisons on the Turkish frontiers in Europe, formerly used it in their ordinary intercourse. The Hungarians, however, and the natives of Wallachia, speak a different language, one which bears evident marks of Tartarian origin, in short a dialect of that language which was spoken by the original Huns. Upon the whole, the Sclavonic is one of the most widely spread languages in Europe, and even extends far into Asia.

SECT. X. MODERN LANGUAGES.

Parent dialects of Europe.

If the different dialects of the various nations which now inhabit the earth, be called languages, the number will be truly great; and vain would be the ambition of that man who should attempt to acquire them, however imperfectly. But there are four, which may be considered as original or mother-languages, and which seem to have given birth to all that are now spoken in Europe. These are the Latin, the Celtic, the Gothic, and the Sclavonic. Let it not, however, be imagined, from the term *original* applied to these languages, that we believe them to have come down to us, without any alteration. We have repeatedly declared our opinion, that there is but one truly original language, from which all others are derivatives variously modified. The four languages just mentioned are original only as being the immediate parents of those which are now spoken in Europe.

Thus, from the *Latin* came, the Portuguese, the Spanish, the French, and the Italian. From the *Celtic* came, the Erse or Gaelic of the Highlands of Scotland, the Welsh, the Irish, and the Basse Bretagne. From the *Gothic* came, the German, the Low Saxon or Low German, the Dutch, the English, in which almost all the noun-substantives are German, and many of the verbs French or Latin, and which is enriched with the spoils of all other languages, including the Danish, the Norwegian, Swedish, Icelandic.

From the *Sclavonian* came, the Polish, the Lithuanian or Lettish, the Bohemian, Transylvanian, Moravian, and the modern Vandalian, as it is still spoken in Lusatia and other parts; the Croatian, the Russian or Muscovite, which, as we have seen, is the purest dialect of this language; the language of the Calmucks and Cossacks; with thirty-two different dialects of nations who inhabit the north-eastern parts of Europe and Asia, and who are descended from the Tartars and Hunno-Scythians. There are polyglott tables containing not only the alphabets, but also the principal or distinctive characteristics of all these languages.

Asiatic Languages.

The languages which are at present spoken generally in Asia are, the Turkish and Tartarian, with their different dialects; the Persian, the Georgian or Iberian, the Albanian or Circassian, the Armenian, the modern Indian, the Formosan, the Hindustanee, the Malabarian, the Warugian, the Tamulic or Damulic, the modern Arabic, the Tongussian, the Mongolian, the language of the Nigarian or Akar Nigarian, the Grusinic or Grusinian, the Chinese, and the Japanese. Here, however, we have only enumerated those Asiatic languages of which we have some knowledge in Europe, and even alphabets, grammars, or other books capable of giving us some information concerning them. But in those vast regions and the adjacent islands, there are doubtless other languages and dialects, of which no distinct account has yet been obtained.

---

[1] See Charpentier, *Eléments de la Langue Russe.*

African Languages. The principal languages of Africa are, the modern Egyptian, the language of the kingdom of Fez, the Moroccan, and the jargons of those savage nations who inhabit the central regions of that great continent. The people on the coast of Barbary speak a corrupt dialect of the Arabic. To these may be added the Chilhic language, otherwise called *Tamazeght;* the Nigritian, and that of Guinea; the Abyssinian, and the language of the Hottentots and Caffres.

(o. o. o. o.)

American Languages. The number of languages which distinguish the different native tribes of America, appears to be still more considerable in that continent than in Africa, where, according to the researches of Seetzen and Vater, there are above a hundred and forty. In this respect, America resembles the Caucasus, Italy previous to the conquest of the Romans, and Asia Minor, when that country contained the Cilicians of Semitic origin, the Phrygians of Thracian or Gothic extraction, the Lydians, and the Celts. Many circumstances contributed to produce the amazing variety of American dialects, but the principal undoubtedly was the absence of all communication between the different native tribes, occasioned partly by their own condition of life, and partly by the nature and configuration of the country they inhabited. But when it is asserted that several hundreds of languages are found in a continent the whole population of which is scarcely equal to that of France, it should be kept in view that we regard as different all those languages which bear the same affinity to each other, not as the German and Dutch, or the Italian and Spanish, but as the Danish and the German, the Chaldaic and the Arabic, the Greek and the Latin. It is a great mistake to suppose, as some have done, that these languages are all separate and independent, having no points of relation, analogy, or resemblance. In proportion as we penetrate into the labyrinth of the American idioms, we discover that several are susceptible of being classed by families; whilst a still greater number remain insulated like the Basque amongst the European, and the Japanese amongst Asiatic languages. This separation, however, may be only apparent; for it may be presumed that languages which appear to admit of no ethnographical classification, have some affinity, either with other languages which have for a long time been extinct, or with the idioms of nations which have never yet been visited by travellers. The greater number of the American languages, even such as exhibit the same differences from each other as the languages of Teutonic origin, the Celtic, and the Sclavonian, bear a certain analogy in the whole of their organization or structure; particularly in the complication of their grammatical forms, in the modification of the verb according to the nature of its syntactical construction, and in the number of particles employed additively either as affixes or as suffixes. Such an uniform tendency of idioms betrays, if not a community of origin, at least a great analogy in the intellectual dispositions of the American tribes from the Arctic regions to the Straits of Magelhaens.[1]

Investigations made with scrupulous exactness, by following a method which had not previously been employed in etymological pursuits have proved that there are but few words which are common in the vocabularies of the New and Old World. In eighty-three American languages, examined by Barton and Vater, one hundred and seventy words have been found, the roots of which appear to be the same; and that this analogy is not accidental may be inferred from the circumstance that it does not rest merely on imitative harmony, or that conformity in the organs which produces almost a perfect identity in the first sounds articulated by children. Of the hundred and seventy words which are common to the two continents, three-fifths resemble the Mantchoo, the Tongouss, the Mongul, and the Samoyed; and two-fifths resemble the Celtic and Finnish, the Coptic and the Congo languages. These words have been discovered by comparing the whole of the American languages with the whole of those of the Old World; for as yet we are not acquainted with any American idiom, which appears to have an exclusive correspondence with any of the Asiatic, African, or European languages. Much has been said by some learned writers, respecting the pretended poverty of all the American languages, and the extreme imperfection of their numerical system; but, in the absence of well-authenticated facts, all such statements should be received with caution, being rather deductions from a preconceived theory, than the result of actual investigation. Besides, several idioms which now form the speech of barbarous nations, appear to be the wrecks of languages, once rich, flexible, and belonging to a far more cultivated state of society. Whether the primitive condition of the human race was rude and brutalised, or whether the savage hordes which still exist are descended from nations, whose intellectual faculties, and the languages which reflect them, were equally developed, is a question into which we cannot at present enter. We shall only observe, that the little we know of the history of the Americans, tends to prove that the tribes, whose migrations have been directed from the north to the south, whilst yet dwelling in the arctic regions, employed various idioms, which are now found under the torrid zone; and from this we may by analogy conclude, that the multiplication of languages is a very ancient phenomenon. Perhaps those which we call American belong no more to America than the Magyar or Hungarian, and the Tschoud or Finnish belongs to Europe. It is doubtless true that the comparison between the idioms of the two continents has hitherto led to no important conclusion. But we may nevertheless indulge the hope that this study will become more productive, when a greater number of materials shall have been accumulated to exercise the sagacity of the learned. At present many languages exist in America, and in central and eastern Asia, the mechanism of which is as much unknown to us as that of the Tyrhenian, the Oscan, the Umbrian, and the Sabine.

Conclusion. It was our original intention to conclude this article with some general remarks on the modern languages of Europe, particularly the French, the Italian, the Spanish, and the Portuguese, on the one hand, and on the German and English, on the other. But the length to which it has already extended, and the facility of access to works containing ample information respecting the genius and structure of these languages, render it inexpedient to enter into details which are more or less within the reach of almost every well-informed reader.

---

[1] The natives of America may be divided into two great classes. To the first belong the Esquimaux of Greenland, Labrador, and Hudson's Bay, and the inhabitants of Behring's Straits, Alaska, and Prince William's Sound. The eastern and western branches of this family are united by close similarity of language, though separated by a distance of eight hundred leagues; and the inhabitants of the north-east of Asia are believed to be of the same stock. The second race is dispersed over the various regions of the continent, from the northern parts to the southern extremity. They are larger in size, more warlike, more taciturn, and also differ considerably from the northern class in the colour of their skin, which, according to Humboldt, has been but slightly affected, in either class, by climate or other external circumstances.

Philomathes || Philopœmen.

PHILOMATHES, a lover of learning or science.

PHILOMELA, in fabulous history, was the daughter of Pandion king of Athens, and the sister of Procne, who had married Tereus king of Thrace. Procne separated from Philomela, to whom she was much attached, and spent her time in great melancholy, until she prevailed upon her husband to go to Athens and bring her sister to Thrace. Tereus obeyed; but he had no sooner obtained Pandion's permission to conduct Philomela to Thrace, than he fell in love with her, and resolved to gratify his passion. He dismissed the guards whom the suspicions of Pandion had appointed to watch him; offered violence to Philomela; and afterwards cut out her tongue, that she might not disclose the indignities she had suffered from his barbarity. He confined her in a lonely castle; and having taken every precaution to prevent a discovery, he returned to Thrace, and told Procne that Philomela had died by the way, and that he had paid the last offices to her remains. At this sad intelligence Procne put on mourning for the loss of Philomela; but a year had scarcely elapsed before she was secretly informed that her sister was not dead. Philomela, in her captivity, described on a piece of tapestry her misfortunes and the brutality of Tereus, and privately conveyed it to Procne. The latter was about to celebrate the orgies of Bacchus when she received it, but she disguised her resentment; and as during these festivals she was permitted to rove about the country, she hastened to deliver her sister Philomela from her confinement, and concerted with the latter the best measures for punishing the cruelty of Tereus. She murdered her son Itylus, then in the sixth year of his age, and served him up as food to her husband during the festival. Tereus, in the midst of his repast, called for Itylus; but Procne immediately informed him that he was then feasting on his flesh, when Philomela, by throwing upon the table the head of Itylus, convinced the monarch of the cruelty of the scene. He drew his sword to punish Procne and Philomela; but whilst about to stab them to the heart, he was changed into a hoopoe, Philomela into a nightingale, Procne into a swallow, and Itylus into a pheasant. This tragedy happened at Daulis, in Phocis; but Pausanias and Strabo. who mention the whole of the story, are silent respecting the transformation; and the former observes, that Tereus, after this bloody repast, fled to Megara, where he laid violent hands on himself. The inhabitants of the place raised a monument to his memory, where they offered yearly sacrifices, and placed thereon small pebbles instead of barley. It was on this monument that the birds called hoopoes were first seen, and hence the fable of his metamorphosis. Procne and Philomela died of excessive grief and melancholy; and as the voice of the nightingale and the swallow is peculiarly plaintive and mournful, the poets have embellished the fable by supposing that the two unfortunate sisters were changed into these birds.

PHILOPŒMEN, a celebrated general of the Achæan league, was born in Megalopolis, a city of Arcadia, in Peloponnesus, and from his very infancy discovered a strong inclination to the profession of arms. Having been nobly educated by Cassander of Mantinea, a man of great probity and uncommon abilities, he was no sooner able to bear arms than he entered amongst the troops which the city of Megalopolis sent to make incursions into Laconia, and in these inroads never failed to give some remarkable instance of his prudence and valour; but when there were no troops in the field, he used to employ his leisure in hunting and other manly exercises. When Cleomenes, king of Sparta, attacked Megalopolis, Philopœmen displayed equal courage and greatness of soul. He also signalized himself some time afterwards in the battle of Sellasia, where Antigonus gained a complete victory over Cleomenes. Antigonus, who had been an eye-witness of his prudent and intrepid behaviour, endeavoured to gain him over to his interest; but the patriotic Greek rejected all his offers, having an utter aversion to a court life, which he compared to that of a slave, conceiving a courtier to be only a slave of a better condition. As he could not live idle and inactive, he proceeded to the island of Crete, which was then engaged in war, and served as a volunteer, until he acquired a complete knowledge of the military art; for the inhabitants of that island were in those days accounted excellent warriors, and were scarcely ever at peace amongst themselves. Philopœmen, having served some years with the troops of the island, returned home, and upon his arrival was appointed general of the horse; a command in which he behaved so well, that the Achæan cavalry, heretofore of no reputation, became in a short time famous all over Greece. He was soon afterwards appointed general of the Achæan forces, and applied himself to re-establish military discipline amongst the troops of the republic, which he found in a very low condition, and universally despised by their neighbours. Aratus, indeed, was the first who raised the Achæan state to that pitch of power and glory to which it attained; but the success of his enterprise was not so much owing to his courage and intrepidity as to his prudence and politics. As he depended on the friendship of foreign princes, and their powerful succours, he neglected military discipline at home; but the instant Philopœmen was appointed commander-in-chief, he roused the courage of his countrymen, and laboured to put them into a condition to defend themselves without the assistance of foreign allies. With this view he made great improvements in the Achæan discipline, changing the manner of their exercise, as well as their arms, which were both very defective. For the space of eight months he had exercised his troops every day, making them perform every movement and evolution, and accustoming them to manage with dexterity their arms, when news reached him that Machanidas was advancing, at the head of a numerous army, to invade Achaia. He was glad of this opportunity to try how the troops had profited by his discipline; and accordingly, taking the field, he met the enemy in the territories of Mantinea, where a decisive battle was fought, in which the Achæans were completely victorious. On this occasion the Lacedæmonians lost above 8000 men, of whom 4000 were killed on the spot, and as many taken prisoners. The loss of the Achæans was very inconsiderable, and those who fell were mostly mercenaries. This happened about the year before Christ 204.

But what most contributed to raise the fame and the reputation of Philopœmen, was his uniting the powerful city of Lacedæmon to the Achæan commonwealth, by which means the Achæans were enabled to eclipse all the other states of Greece. In this transaction, which happened in the year 191, we cannot help noticing one circumstance, which, in our opinion, reflects greater lustre on Philopœmen than all his warlike exploits. The Lacedæmonians, overjoyed to find themselves delivered from the oppressions under which they had long groaned, ordered the palace and furniture of Nabis to be sold, and the sum thence accruing, to the amount of 120 talents, to be presented to Philopœmen, as a token of their gratitude; and deputies were appointed to carry the money, and desire Philopœmen, in the name of the senate, to accept of the present. But so great was the opinion which the Spartans entertained of his probity and disinterestedness, that no one could be found who would undertake to offer the present; and, struck with veneration and the fear of displeasing him, they all begged to be excused. At last, by a public decree, they obliged one Timolaus, who had formerly been his guest, to repair to Megalopolis, where Philopœmen then lived, and offer him this testimony of their regard. Timolaus, with great reluctance, set out for Megalopolis, where he was kindly received and entertained by Philopœmen. Here he had an opportunity of observing the strictness of his conduct, the greatness

Philosopher's Stone.

of his mind, the frugality of his life, and the regularity of his manners; all which struck him with such awe, that he durst not once mention the present he had come to offer, and, alleging some other pretence for his journey, he returned home with the money. The Lacedæmonians sent him again; but still he could not prevail on himself to mention the true cause of his journey. At last, being sent a third time, he ventured, with reluctance, to apprise Philopœmen of the offer he had to make in the name of the Lacedæmonians. Philopœmen heard him with great calmness; but the instant he had finished, the general set out with him for Sparta, where, after acknowledging his obligation to the Spartans, he advised them to lay out their money in reforming or purchasing those miscreants who divided the citizens, and set them at variance by means of their seditious discourses, that, being paid for their silence, they might not occasion so many distractions in the government. "It is much more advisable," said he, "to stop an enemy's mouth than a friend's; as for me, I shall always be your friend, and you shall reap the benefit of my friendship without expense."

About two years afterwards, the city of Messene withdrew itself from the Achæan league. Philopœmen attacked them, but was wounded, taken prisoner, and poisoned by the magistrates; and thus died one of the greatest heroes whom Greece or any other country had ever produced. He was no way inferior in valour, military knowledge, and virtue, to any of the boasted heroes of Rome. Had Achaia been nearer to an equality with Rome, he would have preserved his country from the yoke which the Roman republic imposed upon it. Both the Greek and Roman writers place him on a level with Hannibal and Scipio, who were his contemporaries, and died the same year. They allow him to have been not only one of the greatest commanders, but also one of the greatest statesmen, of his age. To his valour and prudence Achaia owed her glory, which upon his death began to decline; for after him there was none in that republic capable of opposing her enemies with the same steadiness and prudence. Philopœmen was therefore called the last of the Greeks, as Brutus was afterwards styled the last of the Romans. See the article Army.

PHILOSOPHER, a person versed in philosophy, or one who makes profession of, and applies himself to, the study of wisdom or real knowledge.

Philosopher's *Stone*, the great object of alchemy, a long-sought-for preparation, which, when found, was to transmute all the true mercurial part of metal into pure gold, better than any that is obtained from mines, or perfected by the refiner's art.

Some Greek writers belonging to the fourth and fifth centuries speak of this art as being then known; and towards the end of the thirteenth century, when the learning of the East had been imported by the Arabians, the same pretensions began to spread throughout Europe. It is supposed that this art, called *alchemy*, was of Egyptian origin; and that when the ancient Greek philosophers travelled into Egypt, they brought back some of the allegorical language of this Egyptian art, which, being ill understood, afterwards passed into their mythology. Alchemy was the earliest branch of chemistry, considered as a philosophical science. In the other parts of chemical knowledge, facts preceded reasoning or speculation; but in alchemy all was originally speculative.

The alchemists supposed that the general principles of metals consisted chiefly of two substances, which they called mercury and sulphur. They apprehended, that the pure mercurial, sulphureous, or other principles of which they imagined gold to be composed, were contained separately in other bodies; wherefore they endeavoured to collect these principles, and to concoct and incorporate them by long digestions; and by thus conjoining the principles of gold, they expected that gold would be produced. But the alchemists pretended to a product of a higher order, *called the elixir, the medicine for metals, the tincture, the philosopher's stone*, which, by being projected on a large quantity of any of the inferior metals in fusion, should change them into fine gold; or which, being laid on a plate of silver, copper, or iron, and moderately heated, should sink into the metal, and change into gold all the parts to which it was applied; or which, on being properly heated with pure gold, should change the gold into a substance of the same nature and virtue with itself, so as to be susceptible of perpetual multiplication, and, by continued coction, to have its power more and more exalted, so as to be able to transmute greater and greater quantities of the inferior metals, according to its different degrees of perfection.

The alchemists attempted to arrive at the making of gold by three different methods. The first was by separation; for every metal yet known was supposed to contain some quantity of gold, though, in most, the quantity was believed to be so little as not to defray the expense of disengaging it. The second was by maturation. The alchemists considered mercury as the basis and matter of all metals; they thought that quicksilver purged from all heterogeneous bodies would be much heavier, denser, and simpler, than the native quicksilver, and that by subtilizing, purifying, and digesting it with much labour, and by long operations, it was possible to convert it into pure gold. This method was only for mercury. With respect to the other metals, it was ineffectual, because their matter was not pure mercury, but had other heterogeneous bodies adhering to it; and because the digestion, by which mercury is turned into gold, would not succeed in other metals, from their not having been long enough in the mines. Weight is the inimitable character of gold. But mercury, according to them, has always some impurities in it, which are lighter than mercury; and could these be purged away, which they thought not impossible, mercury would be as heavy as gold, and what was as heavy as gold was gold, or at least might very easily be made gold. The third method was by transmutation, or by turning all metals readily into pure gold, by melting them in the fire, and casting a little quantity of a certain preparation into the fused matter; upon which the fæces would be volatilized and burned, or carried off, and the rest of the mass would be turned into pure gold. That which was to work this change in the metals received the denomination of the *philosopher's stone.*

The following historical notices on this curious subject occur in Holt's Charaeters of the Kings and Queens of England. "The opinion," says he, "that one metallic or other foreign substance might be changed into another, was, it seems, at this time (in the reign of Henry VI. of England) propagated by certain chemists, whose observations on the surprising effects and alterations produced in certain substances by the force of heat carried their imaginations beyond what sound judgment might warrant; the first instance of which on record is in Rymer's *Fœdera* (vol. xi. p. 68), wherein Henry VI. grants a license to John Cobbe, freely to work in metals, he having, by philosophical art, found out a method of transmuting imperfect metals into perfect gold and silver. This pretended secret, known afterwards by the name of the *philosopher's stone* or *powder*, was encouraged by four licenses, granted to different projectors, during this reign, and at sundry times after during this century particularly, and in succeeding times all over Europe."

PHILOSOPHY.[1]

History.
Definition.

Philosophy is a word derived from the Greek, and literally signifies the *love of wisdom.* In its usual acceptation, however, it denotes a science, or collection of sciences, of which the universe is the object; and of the term thus employed many definitions have been given, differing from one another according to the different views of their several authors. By Pythagoras, philosophy is defined *ἐπιστημη των ὀντων*, the knowledge of things existing; by Cicero, after Plato, "scientia rerum divinarum et humanarum cum *causis*;" and by the illustrious Bacon, *interpretatio naturæ.* Whether any of these definitions be sufficiently precise, and at the same time sufficiently comprehensive, may perhaps be questioned; but if philosophy in its utmost extent be capable of being adequately defined, it is not here that the definition should be given. "Explanation," says an acute writer,[2] "is the first office of a teacher; definition, if it be good, is the last of the inquirer after truth; but explanation is one thing, and definition quite another." It may be proper, however, to observe, that the definition given by Cicero is better than that of Pythagoras, because the chief object of the philosopher is to ascertain the *causes* of things; and in this consists the difference between his studies and those of the natural historian, who merely enumerates phenomena, and arranges them into separate classes.

Objects of philosophy.

The principal objects of philosophy are, God, nature, and man. That part of it which treats of God is called Theology; that which treats of nature, Physics and Metaphysics; and that which treats of man, Logic and Ethics. That these are not separate and independent sciences, but, as Bacon expresses it,[3] branches from the same trunk, we shall endeavour to show, after we have, agreeably to our usual plan, given a short history of philosophy from the earliest ages to the present day.

To attempt to assign an origin to philosophy would be ridiculous; for every man endeavours to ascertain the causes of those changes which he observed in nature; and even children themselves are inquisitive after that which produces the sound of their drums and their rattles. Children, therefore, and the most illiterate vulgar, have in all ages been philosophers. But the first people amongst whom philosophy was cultivated as a profession was probably the Chaldeans. We certainly read of none earlier; for although we have more authentic accounts of the Hebrews than of any other nation of remote antiquity, and have reason to believe that no people was civilized before them, yet the peculiar circumstances in which they were placed rendered all philosophical investigation to them useless, and even tended to suppress the very spirit of inquiry. The Egyptians indeed pretended to be the first of nations, and to have spread the blessings of religion and the light of science amongst every other people; but, from the earliest records now extant, there is reason to believe that the Chaldeans were a civilized and powerful nation before the Egyptian monarchy was founded.

Histor

Philosop of the Ch deans.

Of the Chaldean philosophy much has been said, but very little is known. Astronomy seems to have been their favourite study; and at the era of Alexander's conquest of their country, they boasted that their ancestors had continued their astronomical observations throughout a period of 470,000 years. Extravagant claims to antiquity have been common in all nations.[4] Calisthenes, who attended the Macedonian conqueror, was requested by Aristotle to inform himself concerning the origin of science in Chaldea; and upon examining into the grounds of this report, he found that their observations reached no farther backwards than 1903, or 2234 years before the Christian era. Even this is a remoter antiquity than Ptolemy allows to their science; for he mentions no Chaldean observations prior to the era of Nabonassar, or 747 years before Christ. That they cultivated something which they called philosophy at a much earlier period than this, cannot be questioned; for Aristotle,[5] on the credit of the most ancient records, speaks of the Chaldean magi as prior to the Egyptian priests, who were certainly men of learning before the time of Moses. For any other science than that of the stars we do not read that the Chaldeans were famous; and this seems to have been cultivated by them merely as the foundation of judicial astrology. Persuading the multitude that all human affairs are influenced by the stars, and professing to be acquainted with the nature and laws of this influence, their wise men pretended to calculate nativities, and to predict good and bad fortune.[6] This was the source of idolatry and various superstitions; and whilst the Chaldeans were given up to such puerilities, true science could not be much indebted to their labours. If any credit be due to Plutarch and Vitruvius, who quote Berosus, it was the opinion of the Chaldean wise men that an eclipse of the moon happens when that part of its body which is destitute of fire is turned towards the earth. Their cosmogony, as given by Berosus, and preserved by Syncellus, seems to be this, that all things in the beginning consisted of darkness and water; that a divine power, dividing this humid mass, formed the world; and that the human mind is an emanation from the divine nature.[7]

The large tract of country which comprehended the empires of Assyria and Chaldea was the first peopled region on earth. From that country, therefore, the rudiments of science must have been propagated in every direction throughout the rest of the world; but what particular people made the earliest figure, after the Chaldeans, in the history of philosophy, cannot be certainly known. The claim of the Egyptians is probably best founded; but as their science was the immediate source of that of the Greeks, we shall defer what we have to say of it, on account of the connection between the parent and the offspring, and turn our attention from Chaldean to Indian philosophy, as it has been cultivated from a very early period by the Brahmins and Gymnosophists. We pass over Persia, because we know not of any science peculiar to that kingdom except the doctrines of the magi, which were religious rather than philosophical.

---

[1] This article, which was written by the late Professor Robison for the *third* edition of the present work, has, after some slight alterations, been retained, as well on account of the frequent references to it from the article Physics, contributed by the same distinguished author, as on account of the elaborate and somewhat peculiar view which it takes of Lord Bacon's philosophy. On this latter subject, however, the reader will do well to turn to the invaluable commentary upon the *Novum Organum*, contained in the *Second* Dissertation prefixed to the present edition.

Indian philosophy.

From whatever quarter India received its wisdom, we are certain that its philosophers were held in high repute at a period of very remote antiquity, since they were visited by Pythagoras and other sages of ancient Greece, who travelled in pursuit of knowledge. Yet they seem to have been in that early age, as well as at present, more distinguished for the severity of their manners than for the acquisition of science; and, as Dr Enfield observes, they appear to have more resembled modern monks than ancient philosophers. The Brahmans or Brahmins, it is well known, are all of one tribe; and the most learned of them are in their own language called Pundits. The Greek writers, however, mention a society called *Samanæans*, who, voluntarily devoting themselves to the study of divine wisdom, gave up all private property, committing their children to the care of the state, and their wives to the protection of their relations. This society was supported at the public expense; and its members spent their time in contemplation, in conversation on divine subjects, or in acts of religion.

The philosophy of the Indians has indeed from the beginning been engrafted upon their religious dogmas, and seems to be a compound of fanatical metaphysics and extravagant superstition, without the smallest seasoning of rational physics. Very unlike the philosophers of modern Europe, of whom a great part labour to exclude the agency of mind from the universe, the Pundits of Hindustan allow no powers whatever to matter, but introduce the Supreme Being as the immediate cause of every effect, however trivial. "Brahm, *the Spirit of God*," says one of their most revered Brahmins, "is absorbed in self-contemplation. The same is the mighty lord, who is present in every part of space, whose omnipresence, as expressed in the Reig Beid or Rigveda, I shall now explain. Brahm is one, and to him there is no second; such is truly Brahm. His omniscience is self-inspired or self-intelligent, and its comprehension includes every possible species. To illustrate this as far as I am able, the most comprehensive of all comprehensive faculties is omniscience; and being self-inspired, it is subject to none of the accidents of mortality, conception, birth, growth, decay, or death; neither is it subject to passion or vice. To it the three distinctions of time, past, present, and future, are not. To it the three modes of being are not.[1] It is separated from the universe, and independent of all. This omniscience is named Brahm. By this omniscient Spirit the operations of God are enlivened. By this Spirit also the twenty-four powers[2] of nature are animated. How is this? As the eye by the sun, as the pot by the fire, as iron by the magnet,[3] as variety of imitations by the mimic, as fire by the fuel, as the shadow by the man, as dust by the wind, as the arrow by the spring of the bow, and as the shade by the tree, so by this Spirit the world is endued with the powers of intellect, the powers of the will, and the powers of action. Hence, if it emanates from the heart by the channel of the ear, it causes the perception of sounds; if it emanates from the heart by the channel of the skin, it causes the perception of touch; if it emanates from the heart by the channel of the eye, it causes the perception of visible objects; if it emanates from the heart by the channel of the tongue, it causes the perception of taste; if it emanates from the heart by the channel of the nose, it causes the perception of smell. This also invigorating the five members of action, and invigorating the five members of perception, and invigorating the five elements, and invigorating the five senses, and invigorating the three dispositions of the mind, causes the creation or the annihilation of the universe, whilst itself beholds every thing as an indifferent spectator."[4]

From this passage it is plain that all the motions in the universe, and all the perceptions of man, are, according to the Brahmins, caused by the immediate agency of the Spirit of God, which seems to be here considered as the soul of the world. But it appears, from some papers in the Asiatic Researches, that the most profound of these oriental philosophers, and even the authors of their sacred books, believe not in the existence of matter as a separate substance, but hold an opinion respecting it very similar to that of the celebrated Berkeley. The Vedants, says Sir William Jones, unable to form a distinct idea of brute matter independent of mind, or to conceive that the work of Supreme Goodness was left a moment to itself, imagine that the Deity is ever present to his work, and constantly supports a series of perceptions, which in one sense they call *illusory*, though they cannot but admit the reality of all created forms, as far as the happiness of creatures can be affected by them. This is the very immaterialism of Berkeley; and in proof that it is the genuine doctrine of the Brahmins, the learned president quotes the *Bhágavat*, which is believed to have been pronounced by the Supreme Being, and in which is the following sentence: "Except the *first cause*, whatever may appear, and may not appear, in the mind, know that to be the mind's *Máyá*, or delusion, as light, as darkness."

We have shown elsewhere (see METAPHYSICS), that the metaphysical doctrines of the Brahmins respecting the human soul differ not from those of Pythagoras and Plato; and that they believe it to be an emanation from the great soul of the world, which, after many transmigrations, will be finally absorbed in its parent substance. In proof of their believing in the metempsychosis, Mr Halhed gives us the following translation of what, he says, is a beautiful stanza in the Gēētā: "As, throwing aside his old clothes, a man puts on others that are new; so our lives, quitting the old, go to other newer animals."

Physics and astronomy of the Brahmins.

From the Brahmins believing in the soul of the world not only as the sole agent, but as the immediate cause of every motion in nature, we can hardly suppose them to have made any great progress in that science which in Europe is cultivated under the name of Physics. They have no inducement to investigate the laws of nature, because, according to the first principles of their philosophy, which, together with their religion, they believe to have been revealed from heaven, every phenomenon, however regular, or however anomalous, is produced by the voluntary act of an intelligent mind. Yet if they were acquainted with the use of fire-arms four thousand years ago, as Mr Halhed seems to

---

[1] To be awake, to sleep, and to be absorbed in a state of unconsciousness, that is, in a kind of trance.

[2] The twenty-four powers of nature, according to the Brahmins, are the five elements, fire, air, earth, water, and akash (a kind of subtile æther); the five members of action, the hand, foot, tongue, anus, and male organ of generation; the five organs of perception, the ear, eye, nose, mouth, and skin; the five senses, which they distinguish from the organs of sensation; the three dispositions of the mind, desire, passion, and tranquillity; and the power of consciousness.

[3] If the work from which this extract is quoted be of as great antiquity as Mr Halhed supposes, the Brahmins must have been acquainted with the phenomena of magnetism at a much earlier period than any other philosophers of whom history makes mention.

[4] Preliminary Dissertation to Halhed's Gentoo Laws.

History.

believe, he who made that discovery must have had a very considerable knowledge of the powers of nature; for though gunpowder may have been discovered by accident in the East, as it certainly was in the West many ages afterwards, it is difficult to conceive how mere accident could have led any man to the invention of a gun. In astronomy, geometry, and chronology, too, they appear to have made some proficiency at a very early period. Their chronology and astronomy are indeed full of those extravagant fictions which seem to be essential to all their systems; but their calculation of eclipses, and their computations of time, are conducted upon scientific principles.

"It is sufficiently known," says Mr Davis,[1] "that the Hindu division of the ecliptic into signs, degrees, &c. is the same as ours; that their astronomical year is sidereal, or containing that space of time in which the sun, departing from a star, returns to the same; that it commences on the instant of his entering the sign Aries, or rather the Hindu constellation Mésha; that each astronomical month contains as many even days and fractional parts as he stays in each sign; and that the civil differs from the astronomical account of time only in rejecting those fractions, and beginning the year and month at sunrise, instead of the intermediate instant of the artificial day or night. Hence arises the unequal portion of time assigned to each month, dependent on the situation of the sun's apsis, and the distance of the vernal equinoctial colure from the beginning of Mésha in the Hindu sphere; and by these means they avoid those errors which Europeans, from a different method of adjusting their calendar by intercalary days, have been subject to."

Mr Davis observes, that an explanation of these matters would have led him beyond his purpose, which was only to give a general account of the method by which the Hindus compute eclipses, and to show that the science of astronomy is as well known amongst them now as ever it was amongst their ancestors. This he does very completely; but in the present short historical sketch we can neither copy nor abridge his memoir. Suffice it to say, that he has shown the practical part of the Hindu astronomy to be founded on mathematical principles; and that the learned Pundits appear to have truer notions of the form of the earth and the economy of the universe than those which are ascribed to their countrymen in general.

The same writer likewise shows, that the prodigious duration which the Hindus attribute to the world, is the result of a scientific calculation, founded indeed upon very whimsical principles. "It has been common with astronomers to fix on some epoch, from which, as from a radix, to compute the planetary motions; and the ancient Hindus chose that point of time counted back, when, according to their motions as they had determined them, they must have been in conjunction in the beginning of Mésha or Aries, and coeval with which circumstance they supposed the creation. This, as it concerned the planets only, would have produced a moderate term of years compared with the enormous antiquity that will be hereafter stated; but having discovered a slow motion of the nodes and apsides also, and taken it into computation, they found it would require a length of time corresponding with 1,955,884,890 years, now expired, when they were so situated, and 2,364,115,110 years more before they would return to the same situation again, forming together the grand anomalistick period denominated a *Calpa*, and fancifully assigned as the day of Brahma."

Strange notions of the universe.

But although the mathematical part of the astronomy of the Pundits is undoubtedly respectable, their physical notions of the universe are in the highest degree ridiculous and extravagant. In the Vedas and Puranas, writings of which no devout Hindu can dispute the divine authority, eclipses are said to be occasioned by the intervention of the monster *Rahu*, and the earth to be supported by a series of animals. "They suppose," says Mr Halhed, "that there are fourteen spheres, seven below and six above the earth. The seven inferior worlds are said to be altogether inhabited by an infinite variety of serpents, described in every monstrous figure that the imagination can suggest. The first sphere above the earth is the immediate vault of the visible heavens, in which the sun, moon, and stars are placed. The second is the first paradise, and general receptacle of those who merit a removal from the lower earth. The third and fourth are inhabited by the souls of those men who, by the practice of virtue and dint of prayer, have acquired an extraordinary degree of sanctity. The fifth is the reward of those who have all their lives performed some wonderful act of penance and mortification, or who have died martyrs for their religion. The highest sphere is the residence of Brahma and his particular favourites, such as those men who have never uttered a falsehood during their whole lives, and those women who have voluntarily burned themselves with their husbands. All these are absorbed in the divine essence."

Ethic the Hi

On ethics, the Hindus have nothing that can be called philosophy. Their duties, moral, civil, and religious, are all laid down in their Vedas and Shasters, and enjoined by what they believe to be divine authority, which supersedes all reasoning concerning their fitness or utility. The business of their Pundits is to interpret these books, which are extremely ancient, and written in a language that has long been unintelligible to every other order of men; but no Pundit will alter the text, however impossible to be reconciled to principles established in his own practice of astronomy. On such occasions, the usual apology for their sacred books is, that "such things may have been so formerly, and may be so still; but that for astronomical purposes astronomical rules must be followed."[2] The great duties of morality have been prescribed in every religious code; and they are not overlooked in that of the Hindus, although the highest merit that a Brahmin can have consists in voluntary acts of abstinence and mortification, and in contempt of death.

Philo of the bians Chine

Of the ancient philosophy of the Arabians and Chinese nothing certain can be said; and the narrow limits of such an abstract as this do not admit of our mentioning the conjectures of the learned, which contradict each other, and are all equally groundless. There is indeed sufficient evidence that both nations were at a very early period observers of the stars, and that the Chinese had even a theory by which they foretold eclipses; but there is reason to believe that the Arabians, like other people in their circumstances, were nothing more than judicial astrologers, who possessed not the smallest portion of astronomical science. Pliny makes mention of their magi, whilst later writers tell us that they were famous for their ingenuity in solving enigmatical questions, and for their skill in the arts of divination. But the authors of Greece are silent concerning their philosophy; and there is not an Arabian book of greater antiquity than the Koran extant.

Early ence Phœ cians.

Leaving therefore regions so barren of information, let us pass to the Phœnicians, whose commercial celebrity has induced many learned men to allow them great credit for early science. If it be true, as seems highly probable, that the ships of this nation had doubled the Cape and almost encompassed the peninsula of Africa long before the era of Solomon, we cannot doubt that the Phœnicians had made great proficiency in the art of navigation and in the science of astronomy at a period of very remote antiquity. Nor were these the only sciences cultivated by that ancient people. The learned Cudworth has, in our opinion, sufficiently proved that Moschus or Mochus, a Phœnician, who, according to Strabo, flourished before the Trojan war, was the author of the atomic philosophy afterwards adopted by Leucippus, Democritus, and others, amongst the Greeks; and that it was with some of the successors of this sage that, as Jamblichus tells us, Pythagoras conversed at Sidon, and from them received his doctrine of *monads*. Another proof of the early progress of the Phœnicians in philosophy may be found in the fragments of their historian Sanchoniathon, which have been preserved by Eusebius.[1] We are indeed aware that men of great celebrity have called in question the authenticity of those fragments, and even the very existence of such a writer as Sanchoniathon; but for this scepticism we can discover no solid foundation. His history may have been interpolated in some places by the translator Philo-Byblius; but Porphyry, Eusebius, and Theodoret, speak of it as a work of undoubted credit, and affirm that its author flourished before the Trojan war. Now this ancient writer teaches, that, according to the wise men of his country, all things arose at first from the necessary agency of an active principle upon a passive chaotic mass, which he calls *mot.* This chaos, Cudworth thinks, was the same with the elementary water of Thales, who was also of Phœnician extraction; but Mosheim justly observes that it was rather dark air, since Philo translates it ἀεϱα ζοφωδη. Be this as it may, nothing can be more evident than that the Phœnicians must have made some progress in what must surely be considered as philosophy, however false, as early as the era of Sanchoniathon; for speculations concerning the origin of the world never occur to untaught barbarians. Besides Mochus and Sanchoniathon, Cadmus, who introduced letters into Greece, may undoubtedly be reckoned amongst the Phœnician philosophers; for though it is not pretended that the alphabet was of his invention, and though it is by no means certain that the Greeks, at the time of his arrival amongst them, were wholly destitute of alphabetic characters; yet the man who could prevail with illiterate savages to adopt the use of strange characters, must have been a great master of the science of human nature. Several other Phœnician philosophers are mentioned by Strabo; but as they flourished at a later period, and philosophized after the systematic mode of the Greeks, they do not fall properly under our notice. We pass on therefore to the philosophy of Egypt.

---

[1] Asiatic Researches, vol. ii.

[2] Davis's Memoir, in the Asiatic Researches, vol. ii.

tian sophy.

It has already been observed that the Egyptians boasted of being the first of nations, and the authors of all the science which in separate rays illuminated the rest of the world. But though this claim was undoubtedly ill founded, their high antiquity and early progress in the arts of civil life cannot be controverted. The Greeks with one voice confess that all their learning and wisdom came from Egypt, either imported immediately by their own philosophers, or brought through Phœnicia by the sages of the East; and we know, from higher authority than the histories of Greece, that at a period so remote as the birth of Moses the wisdom of the Egyptians was proverbially famous. Yet the history of Egyptian learning and philosophy, although men of the first eminence, both ancient and modern, have bestowed much pains in attempts to elucidate it, still remains involved in clouds of uncertainty. That they had some knowledge of physiology, arithmetic, geometry, and astronomy, are facts which cannot be questioned; but there is reason to believe that even these sciences were in Egypt pushed no farther than to the uses of life. That they believed in the existence of incorporeal substances is certain; because Herodotus assures us that they were the first assertors of the immortality, pre-existence, and transmigration of human souls, which they could not have been without holding those souls to be at least incorporeal, if not immaterial.

The founder of Egyptian learning is generally acknowledged to have been Thoth, Thent, or Taaut, called by the Greeks Hermes, and by the Romans Mercury; but of this personage very little is known. Diodorus Siculus says that he was chief minister to Osiris, and that he improved language, invented letters, instituted religious rites, and taught astronomy, music, and other arts. The same thing is affirmed by Sanchoniathon, whose antiquity has already been mentioned; by Manetho, an Egyptian priest, who flourished during the reign of Ptolemy Philadelphus; and by Plato, whose authority, as he resided long in Egypt, and was himself an eminent philosopher, is perhaps more to be depended upon than that of the other two. In the Philebus we are told that Thoth was the inventor of letters; and lest we should suppose that by these letters nothing more is meant than picture-writing or symbolical hieroglyphics, it is added, that he distinguished between vowels and consonants, determining the number of each. The same philosopher, in his Phædrus, attributes to Thoth the invention of arithmetic, geometry, astronomy, and hieroglyphical learning; and subjoins a disputation said to have been held between him and Thamus, then king of Egypt, concerning the advantage and disadvantage of his newly-invented letters. Thoth boasted that the invention, by aiding memory, would greatly contribute to the progress of science; whilst the monarch contended that it would enervate men's natural faculties, by making them trust to written characters, without exerting the powers of their own minds.

All this, if real, must have happened before the era of Moses; and since it is almost certain that alphabetical characters were in use prior to the exod of the Israelites from Egypt, we may as well allow the invention to Thoth, as give it to an earlier author of unknown name. That arithmetic, geometry, and astronomy, were cultivated in Egypt from the most remote antiquity, is affirmed by all the ancients, and rendered in the highest degree probable by the situation of the country. The first elements of astronomy have certainly been discovered by various nations, whose habits of life led them to the frequent observation of the heavens; and it is observed by Cicero, that the Egyptians and Babylonians, dwelling in open plains, where nothing intercepted the view of the heavenly bodies, naturally devoted themselves to the study of that science. The annual overflowing of the Nile, which broke up the boundaries of their land, would lay the Egyptians under the necessity of adopting some method of settling those boundaries anew; and necessity we know to be the parent of invention. Hence their early acquaintance with practical geometry cannot well be doubted. Their custom of embalming their dead, and the perfection to which they carried that art,[2] shows infallibly their knowledge of the properties of natural substances, and gives some reason to believe that they were not altogether strangers to anatomy; but if we allow them to have been at this early period anatomists acquainted with the power of drugs, we can hardly refuse them some skill in the art of physic, which they themselves traced up to their gods and demigods, to Serapis, Isis, and her son Horus or Apollo.

---

[1] *Præparatio Evangelii.*

[2] It is true that the dissection of some mummies has lessened the high opinion long entertained of the skill of the ancient Egyptians in the art of embalming; yet it must be granted that their knowledge of antiseptic drugs was great, since it is now certainly known, even from these dissections, that by means of such drugs they contrived to preserve rags of cloth from corruption for upwards of three thousand years.

The art of alchemy has been said to have been known by the ancient Egyptians; and, from the author of the Egyptian philosophy, it has been called the Hermetic art. But although this is unquestionably a fiction, there is evidence that they were possessed of one art which is even yet a desideratum in the practice of chemistry. "Moses," we are told,[1] "took the golden calf which his brother had made for idolatrous purposes, and *burnt it in the fire*, and *ground it to powder*, and strewed it on the water, and made the children of Israel drink of it." Had this fact been related by Herodotus or Diodorus Siculus, it would have been deemed sufficient evidence that the Egyptians were even at that early period no strangers to the art of chemistry; and surely the evidence should not be the worse for coming from the pen of the Hebrew lawgiver, who was himself educated in the court of Egypt.

Their knowledge of the solar system.

But although it is thus evident that the rudiments of almost every useful science were known in Egypt from the remotest antiquity, it does not appear that any of them was carried to a great degree of perfection, unless perhaps chemistry alone must be excepted. One would think that no science could have been more indispensably requisite to them than geometry; and yet, though Pythagoras is said to have spent twenty-two years in Egypt studying that science and astronomy, he himself discovered[2] the famous forty-seventh proposition of Euclid's first book after his return to Samos. This, although a very useful, is yet a simple theorem; and since it was not reached by the Egyptian geometry, we cannot suppose that the people of Egypt had then advanced far in such speculations. The same conclusion must be drawn with respect to astronomy; for Thales is said to have been the first who calculated an eclipse of the sun, and we nowhere read that the Egyptians pretended to dispute that honour with him. To this it may be replied, that Pythagoras was in Egypt undoubtedly taught the true constitution of the solar system, and, what is more extraordinary, the doctrine of comets in particular, and of their revolutions, like the other planets, round the sun.[3] We grant that he was taught all this; but it was not scientifically, but dogmatically, as facts which the priests had received by tradition from their early ancestors, and of which they had never questioned the truth nor inquired into the reasons. Of this we need no better proof than that the Pythagorean system of the sun was totally neglected by the Greeks as soon as they began to frame hypotheses and to speculate in philosophy.[4]

But it may appear strange, and certainly is so, that the Egyptian priests, in the days of Pythagoras, should have preserved so great a discovery of their ancestors, and at the same time have totally forgotten the principles and reasoning which led to a conclusion apparently contrary to the evidence of sense. This is a difficulty which we pretend not to remove, although the fact which involves it seems to be beyond the reach of controversy. Perhaps the following observations may throw upon it a feeble light. According to Manetho, the written monuments of the first Thoth were lost or neglected in certain civil revolutions or natural calamities which befell the kingdom of Egypt. After many ages great part of them were recovered by an ingenious interpretation of the symbols which he had inscribed upon ancient columns; and the man who made this interpretation was called the second Thoth, or Hermes Trismegistus. But thrice illustrious as this personage was, it is at least possible that he may have been much inferior to the former Hermes, and have read his writings and transcribed his conclusions without being able to comprehend the principles or reasoning which led to these conclusions. Any man who understands Latin might translate into his own tongue the conclusions of Newton; but much more would be requisite to make him comprehend the demonstrations of his sublime geometry. By what mode of reasoning the first Hermes was led to the true idea of the solar system, or whether it was by reasoning at all, cannot now be known; but it seems very evident, that when the intercourse between the Egyptains and Greeks first commenced, the wisdom of the former people consisted chiefly in the science of legislation and civil policy, and that the philosopher, the divine, the legislator, and the poet, were all united in the same person. Their cosmogony (for all the ancients who pretended to science framed cosmogonies) differed little from that of the Phœnicians already mentioned. They held that the world was produced from chaos by the energy of an intelligent principle; and they likewise conceived that there is in nature a continual tendency towards dissolution. In Plato's *Timæus*, an Egyptian priest is introduced describing the destruction of the world, and asserting that this will be effected by means of water and fire. They conceived that the universe undergoes a periodical conflagration; after which all things are restored to their original form, to pass again through a similar succession of changes.

Their ral scie

"Of preceptive doctrine the Egyptians had two kinds, the one sacred, the other vulgar. The former, which respected the ceremonies of religion and the duties of the priests, was doubtless written in the sacred books of Hermes, but was too carefully concealed to pass down to posterity. The latter consisted of maxims and rules of virtue, prudence, or policy. Diodorus Siculus relates many particulars concerning the laws, customs, and manners of the Egyptians; whence it appears that superstition mingled with and corrupted their notions of morals. It is in vain to look for accurate principles of ethics among an ignorant and superstitious people. And that the ancient Egyptians merited this character is sufficiently evident from this single circumstance, that they suffered themselves to be deceived by impostors, particularly by the professors of the fanciful art of astrology; concerning whom Sextus Empiricus justly remarks, that they have done much mischief in the world, by enslaving men to superstition, which will not suffer them to follow the dictates of right reason."

---

[1] Exodus, xxii. 20.

[2] This discovery he claimed; and his claim was admitted by the Greek writers, without having been directly controverted since. An excellent mathematician, however, has shown that the equality between the square of the hypothenuse of a right-angled triangle, and the sum of the squares on the other two sides, was known to the astronomers of India at a period long prior to that of Pythagoras. Notwithstanding this, it is certainly possible that the sage of Samos may have made the discovery himself, though we think the contrary much more probable; for we agree with the able writer already mentioned, that Pythagoras, who is generally believed to have conversed with Indian Brahmins as well as Egyptian priests, may have derived from them some of the solid as well as the visionary speculations with which he delighted to instruct or amuse his disciples. See Transactions of the Royal Society of Edinburgh, vol. ii.

[3] This is recorded by Aristotle and Plutarch, and thus expressed by Ammianus Marcellinus: "Stellas quasdam, *ceteris similes*, quarum *ortus orbitusque*, quibus sint temporibus præstituti humanis mentibus ignorari (lib. xxv. cap. 10).

[4] *Fixas* in supremis mundi partibus immotas persistere, et planetas his inferiores circa solem revolvi, terram pariter moveri cursu annuo, diurno vero circa axem propriam, et solem ceu focum universi in omnium centro quiescere, antiquissima fuit philosophantium sententia. Ab Ægyptiis autem astrorum antiquissimis observationibus propagatam esse hanc sententiam verisimile est. Et etiam ab illis et a gentibus conterminis ad Græcos, gentem magis philologicam quam philosophicam, philosophia omnis antiquior juxta et senior manasse videtur. Subinde docuerunt Anaxagoras, Democritus, et alii nonnulli, terram in centro mundi immotam stare, et astra omnia in occasum, aliqua celerius, alia tardius moveri, idque in spatiis liberrimis. Namque orbes solidi postea ab Eudoxo, Calippo, Aristotele, introducti sunt; declinante indies philosophia primitus introducta, et novis Græcorum commentis paulatim prævalentibus. *Quibus vinculis* ANTIQUI planetas in spatiis liberis retineri, deque cursu rectilineo perpetuo retractas in orbem regulariter agi docuere, non constat. (Newton *de Mundi Systemate.*)

From Egypt and Phœnicia philosophy passed into Greece, where it was long taught without system, as in the countries from which it was derived. Phoroneus, Cecrops, Cadmus, and Orpheus, were amongst the earliest instructors of the Greeks; and they inculcated Egyptian and Phœnician doctrines in detached maxims, and enforced them, not by strength of argument, but by the authority of tradition. Their cosmogonies were wholly Phœnician or Egyptian disguised under Grecian names; and they taught a future state of rewards and punishments. The planets and the moon Orpheus conceived to be habitable worlds, and the stars to be fiery bodies like the sun; but he taught that they are all animated by divinities, an opinion which prevailed both in Egypt and in the East. It does not appear, however, that he gave any other proof of his doctrines than a confident assertion that they were derived from some god.

Hitherto we have seen philosophy in its state of infancy and childhood, consisting only of a collection of sententious maxims and traditionary opinions; but amongst the Greeks, an ingenious and penetrating people, it soon assumed the form of profound speculation and systematic reasoning. Two eminent philosophers arose nearly at the same period, who may be considered as the parents not only of Grecian science, but of almost all the science which was cultivated in Europe prior to the era of the great Lord Bacon. These were Thales and Pythagoras, of whom the former founded the Ionic school, and the latter the Italic; from which two sprung the various sects into which the Greek philosophers were afterwards divided. A bare enumeration of these sects is all that our limits will admit of; and we shall give it in the perspicuous language and just arrangement of Dr Enfield, referring our readers for a fuller account than we can give of their respective merits to his abridged translation of Brucker's history.

From the *Ionic School* sprung various others: 1. The Ionic sect proper, whose founder Thales had as his successors Anaximenes, Anaxagoras, Diogenes Apolloniates, and Archelaus. 2. The Socratic school, founded by Socrates, the principal of whose disciples were Xenophon, Æschines, Simon, Cebes, Aristippus, Phædo, Euclid, Plato, Antisthenes, Critias, and Alcibiades. 3. The Cyrenaic sect, of which Aristippus was the author; his followers were, his daughter Arete, Hegisias, Anicerris, Theodorus, and Bion. 4. The Megaric or Eristic sect, formed by Euclid of Megara; to whom succeeded Eubulides, Diodorus, and Stilpo, famous for their logical subtilty. 5. The Eliac or Eretriac school, raised by Phædo of Elis, who, although he closely adhered to the doctrine of Socrates, gave name to his school. His successors were Plistanus and Menedemus; the latter of whom, being a native of Eretria, transferred the school and name to his own country. 6. The Academic sect, of which Plato was the founder. After his death, many of his disciples deviating from his doctrine, the school was divided into the old, new, and middle academies. 7. The Peripatetic sect, founded by Aristotle, whose successors in the Lyceum were Theophrastus, Strato, Lycon, Aristo, Critolaus, and Diodorus. Amongst the Peripatetics, besides those who occupied the chair, were also Dicæarchus, Eudemus, and Demetrius Phalereus. 8. The Cynic sect, of which the author was Antisthenes, whom Diogenes, Onesicritus, Crates, Metrocles, Menippus, and Menedemus, succeeded. In the list of Cynic philosophers must also be reckoned Hipparchia, the wife of Crates. 9. The Stoic sect, of which Zeno was the founder. His successors in the porch were Persæus, Aristo of Chios, Herillus, Sphærus, Cleanthus, Chrysippus, Zeno of Tarsus, Diogenes the Babylonian, Antipater, Panætius, and Posidonius.

The Italic school.

Of the *Italic School* were, 1. The Italic sect proper, founded by Pythagoras, a disciple of Pherecydes. The followers of Pythagoras were Aristæus, Mnesarchus, Alcmæon, Ecphantus, Hippo, Empedocles, Epicharmus, Ocellus, Timæus, Archytas, Hippasus, Philolaus, and Eudoxus. 2. The Eleatic sect, of which Xenophanes was the author. His successors, Parmenides, Melissus, Zeno, belonged to the metaphysical class of this sect; Leucippus, Democritus, Protagoras, Diagoras, and Anaxarchus, to the physical. 3. The Heraclitean sect, which was founded by Heraclitus, and soon afterwards expired. Zeno and Hippocrates philosophized after the manner of Heraclitus, and other philosophers borrowed freely from his system. 4. The Epicurean sect, a branch of the Eleatic, had Epicurus for its author; and amongst his followers were Metrodorus, Polyænus, Hermachus, Polystratus, Basilides, and Protarchus. 5. The Pyrrhonic or Sceptical sect, the parent of which was Pyrrho. His doctrine was taught by Timon the Phliasian; and after some interval was continued by Ptolemy, a Cyrenean, and at Alexandria by Ænesidemus.

Of the peculiar doctrines of these sects, the reader will in this work find a short account either in the lives of their respective founders, or under the names of the sects themselves. We shall only observe at present, that although many of them were undoubtedly absurd, and many wicked, it would yet perhaps be going too far to say with some, that the philosophy of Greece became impious under Diagoras, vicious under Epicurus, hypocritical under Zeno, impudent under Diogenes, covetous under Demochares, voluptuous under Metrodorus, fantastical under Crates, scurrilous under Menippus, licentious under Pyrrho, and quarrelsome under Cleanthes. Of the truth of this heavy charge every reader must judge for himself. We are strongly inclined to think that there were virtues and vices peculiar to each sect; "and that the sects themselves had an affinity more or less direct with the different temperaments of man; whence the choice of sectators often depended on physical influence, or a peculiar disposition of their organs. Nothing appears more natural than that those men who were born with great force of mind and strong nerves should discover a predilection for stoicism; while mortals endowed by nature with more delicacy of fibres and keener sensibility fled for refuge to the myrtles of Epicurus. People whose temperaments partook of no extremes, were always inclined either for the Lyceum or the Academy. Such as possessed solidity of understanding ranged themselves with Aristotle; and those who had only genius, or even pretensions to that endowment, went to augment the crowd of Platonists."[1]

Grecian mode of philosophizing.

All the systematical philosophers, however, pursued their inquiries into nature by nearly the same method. Of their philosophy, as well as of ours, the universe, with all that it contains, was the vast object; but the individual things which compose the universe are infinite in number and ever changing; and therefore, according to an established maxim of theirs, incapable of being the subjects of human science.[2] To reduce this infinitude, and to fix those fleeting beings, they established certain definite arrangements or classes, to some of which every thing past, present, or to come, might be referred; and having ascertained, as they thought, all that could be affirmed or denied of these classes, they proved, by a very short process of syllogistic reasoning, that what is true of the class must be true of every individual comprehended under it. The most celebrated of these arrangements is that which is known by the name of categories, which Mr Harris thinks at least as old as the era of Pythagoras, and to the forming of which mankind would, in his opinion, be necessarily led by the following considerations. Every subject of human thought is either substance or attribute; but substance and attribute may each of them be modified under the different characters of universal or particular. Hence there arises a quadruple arrangement of things into *substance universal* and *substance particular*, into *attribute universal* and *attribute particular;* to some one of which four not only our words and ideas, but every individual of that immense multitude of things which compose the universe, may be reduced. This arrangement, however, the learned author thinks too limited; and he is of opinion, that, by attending to the substances with which they were surrounded, the Grecian schools must soon have distinguished between the attributes *essential* to all substances, and those which are only *circumstantial;* between the attributes proper to *natural* substances or bodies, and those which are peculiar to *intelligible* substances or minds. He likewise thinks, that the time and place of the existence of substances not present must soon have attracted their attention; and that, in considering the place of this or that substance, they could hardly avoid thinking of its position or situation. He is of opinion that the superinduction of one substance upon another would inevitably suggest the idea of clothing or habit, and that the variety of co-existing substances and attributes would discover to them another attribute, viz. that of relation. Instead, therefore, of confining themselves to the simple division of substance and attribute, they divided attribute itself into nine distinct sorts, some essential and others circumstantial; and thus, by setting substance at their head, made ten comprehensive universal genera, called, with reference to their Greek name, *categories*, and with reference to their Latin name, *predicaments.* These categories are, Substance, Quality, Quantity, Relation, Action, Passion, When, Where, Situation, and Clothing; which, according to the systematic philosophy of the Greeks, comprehend every human science and every subject of human thought. History, natural and civil, springs, says Mr Harris, out of Substance; mathematics out of Quantity; optics out of Quality and Quantity; medicine out of the same; astronomy out of Quantity and Motion; music and mechanics out of the same; painting out of Quality and Site; ethics out of Relation; chronology out of When; geography out of Where; electricity, magnetism, and attraction, out of Action and Passion; and so in other instances.

---

[1] Pauw's Philosophical Dissertation.

[2] Boethius *in Prædict. et Arist. Physic.* lib. i.

To these categories, considered as a mere arrangement of science, we are not inclined to make many objections. The arrangement is certainly not complete; but this is a matter of comparatively small importance, for a complete arrangement of science cannot, we believe, be formed. The greatest objection to the categories arises from the use which was made of them by almost every philosopher of the Grecian schools; for those sages having reduced the objects of all human science to ten general heads or general terms, instead of setting themselves to inquire, by a painful induction, into the nature and properties of the real objects before them, employed their time in conceiving what could be predicated of substance in general, of this or that quality, quantity, relation, &c. in the abstract; and they soon found, that of such general conceptions as the categories there are but five predicables or classes of predicates in nature. The first class is that in which the predicate is the genus of the subject; the second, that in which it is the species of the subject; the third is, when the predicate is the specific difference of the subject; the fourth, when it is a property of the subject; and the fifth, when it is something accidental to the subject. Having proceeded thus far in their system, they had nothing to do with individuals but to arrange them under their proper categories, which was commonly done in a very arbitrary manner; and then, with the formality of a syllogism, to predicate of each the predicable of the genus or species to which it belonged. But by this method of proceeding, it is obvious that no progress whatever could be made in physical, metaphysical, or ethical science; for if the individual truly belongs to the category under which it is arranged, we add nothing to our stock of knowledge by affirming or denying of it what we had before affirmed or denied of the whole genus; and if it belong not to the category under which we arrange it, our syllogising will only give the appearance of proof to what must, from the nature of things, be an absolute falsehood. It is only by experiments made on various substances apparently of the same kind that they can be certainly known to belong to the same category; and when this is done, all syllogistic reasoning, from the genus to the species, and from the species to the individual, is but solemn trifling, as every proposition in this retrograde course takes for granted the thing to be proved.

Yet this mode of philosophizing spread from Greece almost over the whole world. It was carried by Alexander into Asia, by his successors into Egypt, and it found its way to Rome after Greece became a province of the empire. It was adopted by the Jews, by the fathers of the Christian church, by the Mahommedan Arabs during the caliphate, and continued to be cultivated by the schoolmen throughout all Europe till its futility was exposed by Lord Bacon. The professors of this philosophy often displayed great acuteness; but their systems were built upon mere hypotheses, and supported by syllogistic wrangling. Now and then indeed a superior genius, such as Alhazen, and our countryman Roger Bacon, broke through the trammels of the schools, and, regardless of the authority of the Stagyrite and his categories, made real discoveries in physical science by experiments judiciously conducted on individual substances; but the science in repute still continued to be that of *generals.* It was indeed a combination of absurd metaphysics with more absurd theology; and that which is properly called physics had in Europe no place in a liberal education from the end of the eighth century to the end of the fourteenth. Towards the beginning of this period of darkness, the whole circle of instruction, or the liberal arts as they were called, consisted of two branches, the *trivium* and the *quadrivium;* the former of which comprehended grammar, rhetoric, and dialectics; the latter music, arithmetic, geometry, and astronomy, to which was added, about the end of the eleventh century, the study of a number of metaphysical subtilties equally useless and unintelligible.

Hitherto the works of the ancient Greek philosophers had been read only in imperfect Latin translations; and before the scholastic system was completely established, Plato and Aristotle had been alternately looked up to as an oracle in science. The rigid schoolmen, however, universally gave the preference to the Stagyrite, because his analysis of body into matter and form is peculiarly calculated to keep in countenance the most incredible doctrine of the Roman Catholic church; and upon the revival of Greek learning this preference was continued after the school philosophy had begun to fall into contempt, on account of much useful information contained in some of his writings on subjects of natural history, and his supposed merit as a natural philosopher. At last the intrepid spirit of Luther and his associates set the minds of men free from the tyranny of ancient names, as well in human science as in theology; and many philosophers sprung up in different countries of Europe, who professed either to be *eclectics*, or to study nature, regardless of every authority except that of reason. Of these the most eminent beyond all comparison was Francis Bacon, Lord Verulam.

l Ba-
d

This illustrious man having read with attention the writings of the most celebrated ancients, and made himself master of the sciences which were then cultivated, soon discovered the absurdity of pretending to account for the phenomena of nature by syllogistic reasoning from hypothetical principles; and, with a boldness becoming a genius of the first order, he undertook to give a new chart of human knowledge. This he did in his two admirable works, entitled *De Dignitate et Augmentis Scientiarum;* and *Novum Organum Scientiarum, sive Judicia vera de Interpretatione Naturæ.* In the former of these works, he takes a very minute survey of the whole circle of human science, which he divides into three great branches; history, poetry, and philosophy, corresponding to the three faculties of the mind, memory, imagination, and reason. Each of these general heads is subdivided into minuter branches, and reflections are made upon the whole, which, though we can neither copy nor abridge them, will amply reward the perusal of the attentive reader. The purpose of the *Novum Organum* is to point out the proper method of interpreting nature, which the author shows could never be done by the logic which was then in fashion, but only by a painful and fair induction. "Homo naturæ minister," says he, "et interpres tantum facit et intelligit, quantum de naturæ ordine re, vel mente observaverit; nec amplius scit aut potest. Syllogismus ad principia scientiarum non adhibetur, ad media axiomata frustra adhibetur, cum sit subtilitati naturæ longe impar. Assensum itaque constringit, non res. Syllogismus ex propositionibus constat, propositiones ex verbis, verba notionum tesseræ sunt. Itaque si notiones ipsæ (id quod basis rei est) confusæ sint et temere a rebus abstractæ, nihil in iis quæ superstruuntur, est firmitudinis. Itaque spes est una in *inductione vera.*"

To hypotheses and preconceived opinions, which he calls *idola theatri,* this great man was not less inimical than to syllogisms; and since his days almost every philosopher of eminence, except Descartes and his followers, has professed to study nature according to the method of induction so accurately laid down in the *Novum Organum.* On this method a few improvements have perhaps been made; but notwithstanding these, Lord Bacon must undoubtedly be considered as the author of that philosophy which is now cultivated in Europe, and which will continue to be cultivated as long as men shall have more regard for matters of fact than for hypothetical opinions. Of this mode of philosophizing we shall now give a short, though we hope not inaccurate view, by stating its objects, comparing it with that which it superseded, explaining its rules, and pointing out its uses; and from this view it will appear that its author shares with Aristotle the empire of science.

V of his
pl so-
pl

The universe, that unbounded object of the contemplation, the curiosity, and the researches of man, may be considered in two different points of view. In the first place, it may be considered merely as a collection of existences, related to each other by means of resemblances and distinction, situation, succession, and derivation, as making parts of a whole. In this view it is the subject of pure description. To acquire an acquaintance with, or a knowledge of, the universe in this point of view, we must enumerate all the beings in it, mention all their sensible qualities, and mark all these relations for each. But this would be labour immense; and when done, an undistinguishable chaos. A book containing every word of a language would only give us the materials, so to speak, of this language. To make it comprehensible, it must be put into some form, which will comprehend the whole in a small compass, and enable the mind to pass easily from one word to another related to it. Of all relations amongst words, the most obvious are those of resemblance and derivation. An etymological dictionary, therefore, in which words have been classed in consequence of their resemblances, and arranged by means of their derivative distinctions, will greatly facilitate the acquisition of the language.

View of
Bacon's
Philoso-
phy.

It is just so in nature. The objects around us may be grouped by means of their resemblance, and then arranged in those groups by means of their distinctions and other relations. In this classification we are enabled to proceed by means of the faculty of abstracting our attention from the circumstances in which things differ, and turning it to those only in which they agree. By the judicious employment of this faculty we are able not only to distribute the individuals into classes, but also to distribute those classes into others still more comprehensive, by discovering circumstances of resemblance amongst them; for the fewer the circumstances are which concur to form that resemblance which has engaged our attention, the greater is the number of similar circumstances which are neglected, and the more extensive will be the class of individuals in which the resemblance is observed. Thus a number of individuals resembling each other in the single circumstance of life composes the most extensive kingdom of Animals. If it be required that they shall further resemble in the circumstance of having feathers, a prodigious number of animals are excluded, and we form the inferior class of Birds. We exclude a great number of birds by requiring a further similarity of web feet, and have the order of Anseres. If we add lingua ciliata, we confine the attention to the genus of Anates. In this manner may the whole objects of the universe be grouped, and arranged into kingdoms, classes, orders, genera, and species.

Such a classification and arrangement is called *Natural History,* and must be considered as the only foundation of any extensive knowledge of nature. To the natural historian, therefore, the world is a collection of existences, the subject of descriptive arrangement. His aim is threefold. 1. To observe with care, and describe with accuracy, the various objects of the universe. 2. To determine and enumerate all the great classes of objects; to distribute and arrange them into all their subordinate classes, through all degrees of subordination, till he arrive at what are only accidental varieties, which are susceptible of no farther distribution; and to mark with precision the principles of this distribution and arrangement, and the characteristics of the various assemblages. 3. To determine with certainty the particular group to which any proposed individual belongs. *Description,* therefore, *arrangement,* and *reference,* constitute the whole of his employment; and in this consists all his science.

Did the universe continue unchanged, this would constitute the whole of our knowledge of nature; but we are witnesses of an uninterrupted succession of changes, and our attention is continually called to the *events* which are incessantly happening around us. These form a set of objects vastly more interesting to us than the former, being the sources of almost all the pleasures or pains we receive from external objects. We are therefore much interested in the study of the events which happen around us, and strongly incited to prosecute it. But they are so numerous and so multifarious, that the study would be immense, without some contrivance for abbreviating and facilitating the task. The same help offers itself here as in the study of what may be called *quiescent nature.* Events, like existences, are susceptible of classification, in consequence of resemblances and distinction; and by attention to these, we can acquire a very extensive acquaintance with active nature. Our attention must be chiefly directed to those circumstances in which many events resemble each other, whilst they differ perhaps in a thousand others. Then we must attend to their most general distinctions; then to distinctions of smaller extent, and so on. It is in this way accordingly that we have advanced in our knowledge of active nature, and are gradually, and by no means slowly, forming assem-

View of Bacon's Philosophy.

blages of events more and more extensive, and distributing these with greater and greater precision into their different classes.

In the zealous and attentive prosecution of this task a very remarkable and interesting observation occurs. In describing those circumstances of similarity amongst events, and particularly in distributing them according to those similarities, it is impossible for us to overlook that constancy which is observed in the changes of nature in the events which are the objects of our contemplation. Events which have once been observed to accompany each other are observed always to do so.

Constancy in the changes of nature.

The rising of the sun is always accompanied by the light of day, and his setting by the darkness of night. Sound argument is accompanied by conviction, impulse by motion, kindness by a feeling of gratitude, and the perception of good by desire. The unexcepted experience of mankind informs us that the events of nature go on in certain regular trains; and if sometimes exceptions seem to contradict this general affirmation, more attentive observation never fails to remove the exception. Most of the spontaneous events of nature are very complicated; and it frequently requires great attention and penetration to discover the simple event amidst a crowd of unessential circumstances which are at once exhibited to our view. But when we succeed in this discovery, we never fail to acknowledge the perfect uniformity of the event to what has been formerly observed. But this is not all. We firmly believe that this uniformity will still continue; that fire will melt wax, will burn paper, will harden clay, as we have formerly observed it to do; and whenever we have undoubted proofs that the circumstances of situation are precisely the same as in some former case, though but once observed, we expect with irresistible and unshaken confidence that the event will also be the same.

It is not surely necessary to produce many proofs of the universality of this law of human thought. The whole language and actions of men are instances of the fact. In all languages there is a mode of construction which is used to express this relation as distinct from all others, and the conversation of the most illiterate never confounds them, except when the conceptions themselves are confounded. The general employment of the active and passive verb is regulated by it. *Turris eversa est a militibus; turris eversa est terræ motu*, express two relations, and no schoolboy will confound them. The distinction therefore is perceived or felt by all who can speak grammatically. Nor is any language without general terms to express this relation. Nay, it is a fact in the mind of brutes, who hourly show that they expect the same uses of every subject which they formerly made of it; and without this, animals would be incapable of subsistence, and man incapable of all improvement. From this alone memory derives all its value; and even the constancy of natural operation would be useless if not matched or adapted to our purposes by this expectation of any confidence in that constancy.

After all the labours of ingenious men to discover the foundation of this irresistible expectation, we must be contented with saying that such is the constitution of the human mind. It is an universal fact in human thought; and, for any thing that has yet been discovered, it is an ultimate fact, not included in any other still more general. We shall soon see that this is sufficient for making it the foundation of true human knowledge, all of which must in like manner be reduced to ultimate facts in human thought. We must consider this undoubted feeling, this persuasion of the constancy of nature, as an instinctive anticipation of events similar to those which we have already experienced. The general analogy of nature should have disposed philosophers to acquiesce in this, however unwelcome to their vanity. In no instance of essential consequence to our safety or well-being are we left to the guidance of our boasted reason; God has given us the surer conduct of natural instincts. No case is so important as this. In none do we so much stand in need of a guide which shall be powerful, infallible, and rapid in its decisions. Without it we must remain incapable of all instruction from experience, and therefore of all improvement.

Our sensations are undoubtedly feelings of our mind. But all those feelings are accompanied by an instinctive reference of them to something distinct from the feelings themselves. Hence arises our perception of external objects, and our very notions of this *externeity*. In like manner, this anticipation of events, this irresistible connection of the idea of fire with the idea of burning, is also a feeling of the mind; and this feeling is by a law of human nature referred, without reasoning, to something external as its cause; and, like our sensation, it is considered as a *sign* of that external something. It is like the conviction of the truth of a mathematical proposition. This is referred by us to something existing in nature, to a necessary and external relation subsisting between the ideas which are the subjects of the proposition. The conviction is the sign or indication of this relation by which it is brought to our view. In precisely the same manner, the irresistible connection of ideas is interpreted as the sensation or sign of a necessary connection of external things or events. These are supposed to include something in their nature which renders them inseparable companions. To this bond of connection between external things we give the name of Causation. All our knowledge of this relation of cause and effect, is the knowledge or consciousness of what passes in our own minds during the contemplation of the phenomena of nature. If we adhere to this view of it, and put this branch of knowledge on the same footing with those called the abstract sciences, considering only the relations of ideas, we shall acquire demonstrative science. If we take any other view of the matter, we shall be led into inextricable mazes of uncertainty and error.

Laws of nature explained.

We see, then, that the natural procedure of our faculty of abstraction and arrangement, in order to acquire a more speedy and comprehensive knowledge of natural events, presents them to our view in another form. We not only see them as similar events, but as events naturally and necessarily conjoined. And the expression of resemblance amongst events is also an expression of concomitancy; and this arrangement of events in consequence of their resemblance is in fact the discovery of those accompaniments. The trains of natural appearance being considered as the appointments of the Author of Nature, has occasioned them to be considered also as consequences of laws imposed on his works by their great author, and every thing is said to be regulated by fixed laws. But this is the language of analogy. When a sovereign determines on certain trains of conduct for his subjects, he issues his orders. These orders are laws. He enforces the observance of them by his authority; and thus a certain regularity and constancy of conduct is produced. But should a stranger, ignorant of the promulgation of these laws, and of the exerted authority of the magistrate, observe this uniformity of conduct, he would ascribe it to the genius and disposition of the people; and his observation would be as useful to him for directing the tenor of his own conduct, as the knowledge of the subject himself of the real source of this constancy is for directing his.

It is just so in nature. Whilst the theologian pretends, from his discoveries concerning the existence and superintendence of God, to know that the constant accompaniment of events is the consequence of laws which the great Author and Governor of the universe has imposed on his works, the ordinary philosopher, a stranger to this scene, and to the unsearchable operations of the Supreme Mind, must as-v of on's oso- y.

cribe this constancy to the nature of the things. There is a great resemblance between the expression natural law and grammatical rule. Rule in strict language implies command; but in grammar it expresses merely a generality of fact, whether of flexion or construction. In like manner, a law of nature is to the philosopher nothing but the expression of a generality of fact. A natural or physical law is a generally observed fact; and whenever we treat any subject as a generally observed fact, we treat it physically. It is a physical law of the understanding that argument is accompanied by conviction; it is a physical law of the affection that distress is accompanied by pity; it is a physical law of the material world that impulse is accompanied by motion. And thus we see that the arrangement of events, or the discovery of those general points of resemblance, is in fact the discovery of the laws of nature; and one of the greatest and most important is, that the laws of nature are constant.

O ts of pl sophy.

There is no question that this view of the universe is incomparably more interesting and more important than that which is taken by the natural historian; contemplating everything that is of value to us, and, in short, the whole life and movement of the universe. This study, therefore, has been dignified with the name of Philosophy and of Science; and natural history has been considered as of importance only in as far as it has proved conducive to the successful prosecution of philosophy. But the philosopher claims a superiority on another account. He considers himself as employed in the discovery of causes, saying that philosophy is the study of the objects of the universe as related by causation, and that it is by the discovery of these relations that he communicates to the world such important knowledge. Philosophy, he says, is the science of causes. The vulgar are contented to consider the prior of two inseparably conjoined events as the cause of the other; the stroke on a bell, for instance, as the cause of sound. But it has been clearly shown by the philosopher, that between the blow struck on the bell and the sensation of sound there are interposed a long train of events. The blow sets the bell a trembling; this agitates the air in contact with the bell; this agitates the air immediately beyond it; and thus between the bell and the ear may be interposed a numberless series of events, and as many more between the first impression on the ear and that last impression on the nerve by which the mind is affected. He can no longer therefore follow the nomenclature of the vulgar. Which of the events of this train, therefore, is the cause of the sensation? None of them. It is that something which inseparably connects any two of them, and constitutes their bond of union. These bonds of union or causes he considers as residing in one or both of the connected objects; diversities in this respect must therefore constitute the most important distinctions between them. They are accordingly with great propriety called the qualities, the properties, of these respective subjects.

As the events from which we infer the existence of these qualities of things resemble in many respects such events as are the consequences of the exertion of our own powers, these qualities are frequently denominated powers, forces, energies. Thus, in the instance which has just now been given of the sound of a bell, we infer the powers of impulse, elasticity, nervous irritability, and animal sensibility. In consequence of this inference of a necessary connection between the objects around us, we not only infer the posterior event from the prior, or, in common language, the effect from the cause, but we also infer the prior from the posterior, the cause from the effect. We not only expect that the presence of a magnet will be followed by certain motions in iron filings, but when we observe such motions, we infer the presence and agency of a magnet. Joy is inferred from merriment, poison from death, fire from smoke, and impulse from motion. And thus the appearances of the universe are the indications of the powers of the objects in it. Appearances are the language of nature, informing us of their causes. And as all our knowledge of the sentiments of others is derived from our confidence in their veracity, so all our knowledge of nature is derived from our confidence in the constancy of natural operations. A veracity and credulity necessarily resulting from that law of our mental constitution by which we are capable of speech, conduct us in the one case; and the constancy of nature, and the principle of induction, by which we infer general laws from particular facts, conduct us in the other. As human sentiment is inferred from language, and the existence of external things from sensation, so are the laws of nature, and the powers of natural objects, inferred from the phenomena. It is by the successful study of this language of nature that we derive useful knowledge. The knowledge of the influence of motives on the mind of man enables the statesman to govern kingdoms, and the knowledge of the powers of magnetism enables the mariner to pilot a ship through the pathless ocean.

View of Bacon's Philosophy.

Discoveries of Aristotle and Newton compared.

Such are the lofty pretensions of philosophy. It is to be wished that they should be well founded; for we may be persuaded that a mistake in this particular will be fatal to the advancement of knowledge. An author of great reputation[1] gives us an opportunity of deciding this question in the way of experiment. He says that the ancients were philosophers, employed in the discovery of causes, and that the moderns are only natural historians, contenting themselves with observing the laws of nature, but paying no attention to the causes of things. If he speak of their professed aim, we apprehend that the assertion is pretty just in general. With very few exceptions indeed it may be affirmed of his favourite Aristotle, the philosopher κατ' ἐξοχὴν, and of Sir Isaac Newton. We select these two instances, both because they are set in continual opposition by this author, and because it will be allowed that they were the most eminent students of nature (for we must not yet call them philosophers) in ancient and modern times. Aristotle's professed aim, in his most celebrated writings, is the investigation of causes; and, in the opinion of this author, he has been so successful, that he has hardly left any employment for his successors besides that of commenting upon his works. We must, on the other hand, acknowledge that Newton makes no such pretensions, at least in that work which has immortalized his name, and that his professed aim is merely to investigate the general laws of the planetary motions, and to apply these to the explanation of particular phenomena. Nor will we say that he has left no employment for succeeding inquirers; but, on the contrary, confess that he has only begun the study, has discovered but one law, and has enabled us to explain only the phenomena comprehended in it alone. But he has not been unsuccessful; his investigation has been complete; and he has discovered, beyond all possibility of contradiction, a fact which is observed through the whole extent of the solar system, namely, that every body, nay, that every particle in it, is continually deflected toward every other body, and that every deflection is, in every instance, proportional to the quantity of matter in that body toward which the deflection is directed, and to the reciprocal of the square of the distance from it. He has therefore discovered a physical law of immense extent. Nor has he been in any degree less successful in the explanation of particular phenomena. Of this there cannot be given a better instance

---

[1] Ancient Metaphysics.

View of Bacon's Philosophy.

than the explanation of the lunar motions from the theory of gravity begun by Newton, *Mathesi sua facem præferente*, and now brought to such a degree of perfection, that if the moon's place be computed from it for any moment within the period of two thousand years back, it will not be found to differ from the place on which she was actually observed by one hundredth part of her own breadth.

> Discimus hinc tandem qua causa argentea Phœbe
> Passibus haud æquis eat, et cur, cognita nulli
> Hactenus astronomo, numerorum frena recusat.
> Quæ toties animos veterum torsere sophorum,
> Quæque scholas hodie rauco certamine vexant,
> Obvia conspicimus, nube pellente mathesi;
> Qua superos penetrare domos, et ardua cœli
> Newtoni auspiciis jam dat contingere templa.

We may now perhaps desire the champions of the science of causes to name any one cause which has really been discovered by their great master, whether in the operations of mind or of body. But they must not on this occasion adduce the investigation of any natural law, in which he has sometimes succeeded. With still greater confidence may we challenge them to produce any remarkable instance of the explanation of natural phenomena, either of mind or body. By explanation we mean an account of the production, and an appreciation of all the circumstances, susceptible of a scrupulous comparison with fact, and perfectly consistent with it. It is here that the weakness of this philosopher's pretensions is most conspicuous; and his followers candidly acknowledge, that in the inquiries which proceed by experiment, we have not derived any great assistance from Aristotle's philosophy. But this, say they, does not derogate from the pre-eminence of his philosophy, because he has shown that the particular fields of observation are to be cultivated only by means of experiment. But surely every field of observation is particular. There is no abstract object of philosophical research, the study of which shall terminate in the philosophy of universals. In every kind of inquiry, that cause alone must be supposed to act which we understand so far as to be able to appreciate its effects in particular circumstances, and compare them with fact, and see their perfect coincidence. If we have discovered causes, they are *known* as far as they are discovered. Their genuine effects are known, and therefore the phenomena which result from their agency are understood. When therefore it is acknowledged, as it must be acknowledged, that mankind have made but little advances in the knowledge of nature, notwithstanding the pretended discovery of causes by Aristotle, and the conducting clue of his philosophy, until of late years; and when it is also allowed that *now*, whilst we are every day making great additions to this subordinate knowledge, the causes which Aristotle has discovered are forgotten, and his philosophy is neglected; there is great room for suspecting, to say the least, that either the causes which philosophy pretends to have discovered are not real, or that Aristotle and his followers have not aimed at the discovery of causes, but only at the discovery of natural laws, and have failed in the attempt.

Philosophical causes.

But there seems here to be a previous question: Is it possible to discover a philosophical cause, that something which is neither the prior nor the posterior of the two immediately adjoining events, but their bond of union, and this, too, distinct from the union itself? It is evident that this is an inquiry purely experimental. It is of human knowledge we speak. This must depend upon the nature of the human mind. This is a matter of contingency, known to us only by experiment and observation. By observing all the feelings and operations of the mind, and classing and arranging them like any other object of science, we discover the general laws of human thought and human reasoning; and this is all the knowledge we can ever acqure of it, or of any thing else.

View Baco Philo phy

Much has been written upon this subject. The most acute observation and the soundest judgment have been employed in the study; and we may venture to say that considerable progress has been made in pneumatology. Many laws of human thought have been observed, and very distinctly marked; and philosophers are busily employed, some of them with considerable success, in the distribution of them into subordinate classes, so as to know their comparative extent, and to mark their distinguishing characters, with a precision similar to that which has been attained in botany and other parts of natural history, so that we may hope that this study will advance like others. But in all these researches no phenomena have occurred which look like the perception or contemplation of these separate objects of thought, these philosophical causes, this power *in abstracto*. No philosopher has ever pretended to state such an object of the mind's observation, or attempted to group them into classes.

We may say at once, without entering into any detail, that those causes, those bonds of necessary union between the naturally conjoined events or objects, are not only perceived by means of the events alone, but are perceived solely in the events, and cannot be distinguished from the conjunctions themselves. They are neither the objects of separate observation, nor the productions of memory, nor inferences drawn from reflection on the laws by which the operation of our own minds are regulated; nor can they be derived from other preceptions in the way of argumentative inference. We cannot infer the paroxysm of terror from the appearance of impending destruction, or the fall of a stone when not supported, as we infer the incommensurability of the diagonal and side of a square. This last is implied in the very conception or notion of a square, not as a consequence of its other properties, but as one of its essential attributes; and the contrary proposition is not only false, but incapable of being distinctly conceived. This is not the case with the other phenomenon, or any matter of fact. The proofs which are brought of a mathematical proposition are not the reason of its being true, but the steps by which this truth is brought into our view; and frequently, as in the instance now given, this truth is perceived, not directly, but consequentially, by the inconceivableness of the contrary proposition.

Mr Hu theory *petitio p cipii.*

Mr Hume derives this irresistible expectation of events from the known effect of custom, the association of ideas. The co-related event is brought into the mind by this well-known power of custom, with that vivacity of conception which constitutes belief or expectation. But without insisting on the futility of his theory of belief, it is sufficient to observe, that this explanation begs the very thing to be proved, when it ascribes to custom a power of any kind. It is the origin of this very power which is the subject in dispute. Besides, upon the genuine principles of scepticism, this custom involves an acknowledgment of past events, of a something different from present impressions, which, in this doctrine, if doctrine it can be called, are the only certain existences in nature; and, lastly, it is known that one clear experience is a sufficient foundation for this unshaken confidence and anticipation. General custom can never, upon Mr Hume's principles, give superior vivacity to any particular idea.

Anothe hypoth

This certain nonentity of it as a separate object of observation, and this impossibility to derive the notion of necessary and causal connection between the events of the universe from any source, have induced two of the most acute philosophers of Europe, Leibnitz and Malebranche, to deny that there is any such connection, and to assert that the events of the universe go on in corresponding trains, but without any causal connection, just as a well-regulated clock will keep time with the motions of the heavens, without any kind of dependence upon them. This harmony of events was pre-established by the Author of the universe, in subserviency to the purposes he had in view in its formation; and all those purposes which are cognisable by us may certainly be accomplished by this perfect adjustment. But without insisting on the fantastical wildness of this ingenious whim, it is quite enough to observe, that it also is a begging of the question, because it supposes causation when it ascribes all to the agency of the Deity.

Thus have we searched every quarter, without being able to find a source from which to derive this perception of a necessary connection amongst the events of the universe, or of this confident expectation of the continuance of physical laws; and yet we are certain of the feeling, and of the persuasion, be its origin what it may; for we speak intelligibly on this subject. We speak familiarly of cause, effect, power, energy, necessary connection, motives and their influence, argument and conviction, reasons and persuasion, allurements and emotions, of gravity, magnetism, irritability, &c.; and we carry on conversations on these subjects with much entertainment and seeming instruction. Language is the expression of thought, and every word expresses some notion or conception of the mind; therefore it must be allowed that we have such notions as are expressed by cause, power, energy. But it is here, as in many cases, we perceive a distinction without being able to express it by a definition; and that we do perceive the relation of causation as distinct from all others, and in particular as distinct from the relation of contiguity in time and place, or the relation of agent, action, and patient, must be concluded from the uniformity of language, which never confounds them except on purpose, and when it is perceived. But even here we shall find, that none of the terms used for expressing those powers of substance which are conceived as the causes of their characteristic phenomena, really express any thing different from the phenomena themselves. Let any person try to define the terms gravity, elasticity, sensibility, and the like, and he will find that the definition is nothing but a description of the phenomena itself. The words are all derivatives, most of them verbal derivatives, implying action, gravitation, and so on. As the general resemblances in shape, colour, or otherwise, are expressed by the natural historian by generic terms, so the general resemblances in event are expressed by the philosopher in generic propositions, which, in the progress of cultivation, are also abbreviated into generic terms.

This abundantly explains the consistency of our language on this subject, both with itself and the operations of nature, without, however, affording any argument for the truth of the assumption, that causes are the objects of philosophical research as separate existences; or that this supposed necessary connection is a *necessary truth*, whether supreme or subordinate. But since the perception of it has its foundation in the constitution of the human mind, it seems entitled to the name of a *first principle*. We are hardly allowed to doubt of this, when we consider the importance of it, and the care of nature to secure us, in all things essential to our safety and well-being, from all danger, from inattention, ignorance, or indolence, by an instinct infallible in its information and instantaneous in its decisions. "It would not be like her usual care," says Hume, "if this operation of the mind, by which we infer like effects from like causes, and *vice versa*, were intrusted to the fallacious deduction of our reason, which is slow in its operations, appears not in any degree during the first years of infancy, and in every age and period of human life is extremely liable to error. It is more conformable to her *ordinary caution* to secure so necessary an act of the mind by some instinct, or blind tendency, which may be infallible and rapid in all its operations, may discover itself at the first appearance of life, and may be independent of all the laboured deductions of reason. As she has taught us the use of our limbs, without giving us any knowledge of the nerves and muscles by which they are actuated; so she has implanted in us an instinct, which carries forward the thought in a course conformable to that established among external objects, though we be ignorant of the powers and forces on which this regularity depends."

View of Bacon's Philosophy.

Such a knowledge is quite unnecessary, and therefore causes are no more cognisable by our intellectual powers than colours by a man born blind; nay, whoever will be at the pains to consider this matter agreeably to the received rules and maxims of logic, will find that necessary connection, or the bond of causation, can no more be the subject of philosophical discussion by man than the ultimate nature of truth. It is precisely the same absurdity or incongruity as to propose to examine light with a microscope. Other rational creatures may perceive them as easily as we hear sounds. All that we can say is, that their existence is probable, but by no means certain. Nay, it may be, though we may never know it, that we are not the efficient causes of our own actions, which may be effected by the Deity or by ministering spirits; and this may even be true in the material world. But all this is indifferent to the real occupation of the philosopher, and does not affect either the certainty, the extent, or the utility of the knowledge which he may acquire.

The object of the philosopher the discovery of physical laws.

We are now able to appreciate the high pretensions of the philosopher, and his claim to scientific superiority. We now see that this can neither be founded on any scientific superiority of his object, nor of his employment. His object is not causes, and his discoveries are nothing but the discovery of general facts, the discovery of physical laws; and his employment is the same with that of the descriptive historian. He observes and describes with care and accuracy the events of nature; and then he groups them into classes, in consequence of resembling circumstances, detected in the midst of many others which are dissimilar and occasional. By gradually throwing out more circumstances of resemblance, he renders his classes more extensive; and by carefully marking those circumstances in which the resemblance is observed, he characterizes all the different classes; and by a comparison of these with each other, in respect to the number of resembling circumstances, he distributes his classes according to their generality and subordination; thus exhausting the whole assemblage, and leaving nothing unarranged but accidental varieties. In this procedure it is to be remarked, that every grouping of similar events is, *ipso facto*, discovering a general fact, a physical law; and the expression of this assemblage is the expression of the physical law. And as every observation of this constancy of fact affords an opportunity for exerting the instinctive inference of natural connection between the related subjects, every such observation is the discovery of a power, property, or quality of natural substance. From what has been said, this observation of event is all we know of the connection, all we know of the natural power. And when the philosopher proceeds farther to the arrangement of events, according to their various degrees of complication, he is, *ipso facto*, making an arrangement of all natural powers according to their various degrees of subordinate influence. Thus his occupation is perfectly similar to that of the descriptive historian, namely, classification and arrangement; and this constitutes all the science attainable by both.

Philosophy defined.

Philosophy may therefore be defined the study of the phenomena of the universe, with a view to discover the general laws which indicate the powers of natural substances, to explain subordinate phenomena, and to improve art; or, in compliance with that natural instinct so much spoken of, philosophy is the study of the phenomena of the universe, with a view to discover their causes, to explain subordinate phenomena, and to improve art. The task is undoubtedly

View of Bacon's Philosophy.

difficult, and will exercise our noblest powers. The employment is manly in itself, and the result of it important. It therefore justly merits the appellation of *Philosophy*, although its objects are nowise different from what occupy the attention of other men.

The employment of the philosopher.

The employment of the philosopher, like that of the natural historian, is threefold, viz. *description*, *arrangement*, and *reference*; whilst the objects are not *things*, but *events*. The description, when employed about events, may be more properly termed *history*. A philosophical history of nature consists in a complete or copious enumeration and narration of facts, properly selected, cleared of all unnecessary or extraneous circumstances, and accurately narrated. This constitutes the materials of philosophy. We cannot give a better example of this branch of philosophical occupation than astronomy. From the beginning of the Alexandrian school to this day, astronomers have been at immense pains in observing the heavenly bodies, in order to detect their true motions. This has been a work of prodigious difficulty; for the appearances are such as might have been exhibited although the real motions had been extremely different. Not that our senses give us false information; but we form hasty, and frequently false judgments, from these informations; and call those things deceptions of sense, which are in fact errors of judgment. But the true motions have at last been discovered, and have been described with such accuracy, that the history may be considered as nearly complete. This is to be found in the usual systems of astronomy, where the tables contain a most accurate and synoptical account of the motion, so that we can tell with precision in what point of the heavens a planet has been seen at any instant that can be named.

Phenomenology.

Sir Isaac Newton's Optics is such another perfect model of philosophical history, as far as it goes. This part of philosophy may be called *Phenomenology*. Having in this manner obtained the materials of philosophical description, we must put them into a compendious and perspicuous form, so that a general knowledge of the universe may be easily acquired and firmly retained. This is to be done by classification and arrangement, and this classification must proceed upon resemblances observed in the events; and the subsequent arrangement must be regulated by the distinctions of which those resemblances are still susceptible. This assemblage of events into groups must be expressed. They are facts, therefore the expression must be propositions. These propositions must be what the logicians call general or abstract propositions; for they express, not any individual fact of the assemblage, but that circumstance in which they all resemble. Such propositions are the following: Proof is accompanied by belief; kindness is accompanied by gratitude; impulse is accompanied by motion. These are usually called general facts, but there are none such; every fact is individual. This language, however inaccurate, is very safe from misconstruction, and we may use it without scruple. These propositions are *natural* or *physical laws*, and then the detecting or marking those resemblances in event is the investigation of physical laws; and we may denominate this employment of the philosopher *Investigation*.

In the prosecution of this task, it will be found that the similarities of fact are of various extent. And thus we shall form physical laws of various extent, and we shall also find that some are subordinate to others; for the resemblance of a number of facts in one circumstance does not hinder a part of them from also resembling in another circumstance; and thus we shall find subordinations of fact in the same way as of quiescent qualities. And it is found here, as in natural history, that our assemblage of resembling events will be the more extensive as the number of resembling circumstances is smaller; and thus we shall have kingdoms, classes, orders, genera, and species of phenomena, which are expressed by physical laws of all those different ranks.

View Baco Phil ph

It has already been observed, that this observation of physical laws is always accompanied by a reference of that uniformity of event to a natural bond of union between the concomitant facts which is conceived by us as the cause of this concomitancy; and therefore this procedure of the philosopher is considered as the discovery of those causes, that is, the discovery of those powers of natural substances which constitute their physical relations, and may justly be called their distinguishing qualities or properties. This view of the matter gives rise to a new nomenclature and language. We give to those powers generic names, such as sensibility, intelligence, irritability, gravity, elasticity, fluidity, magnetism, and the like. These terms, without exception, mark resembling circumstances of event; and no other definition can be given of them except a description of these circumstances. In a few cases which have been the subjects of more painful or refined discussion, we have proceeded farther in this abbreviation of language.

Aitiol

We have framed the verb "to gravitate," and also the verbal noun "gravitation," which purely expresses the fact, the phenomenon, but is conceived to express the operation or energy of the cause or natural power. It is of importance to keep in mind this metaphysical remark on these terms; for a want of attention to the pure meaning of the words has frequently occasioned very great mistakes in philosophical science. We may with propriety call this part of the philosopher's employment *Aitiology*.

Kepler' laws a instanc

We shall give an instance of its most successful application to the class of events already adduced as an example of philosophical history or phenomenology. Kepler, a celebrated Prussian astronomer, having maturely considered the phenomena recorded in the tables and observations of his predecessors, discovered, amidst all the varieties of the planetary motions, three circumstances of resemblance, which are now known by the name of Kepler's Laws. 1. All the planets describe ellipses, having the sun in one focus. 2. The elliptical areas described by a planet in the different parts of its orbit are proportional to the times of description. 3. The squares of the periodic times are proportional to the cubes of the mean distances from the sun. By this observation or discovery, the study of the planetary motions was greatly promoted, and the calculation of their appearances was now made with a facility and an accuracy which surpassed all hopes; for the calculation of the place of a planet at any proposed instant was reduced to the geometrical problem of cutting off an area from an ellipse of known dimensions, which should bear the same proportion to the whole area, as the time for the duration of which the motion is required has to the known time of a complete revolution.

These compre hended der the more ge ral law gravitat

Long after this discovery of Kepler, Sir Isaac Newton found that these laws of Kepler were only particular cases of a fact or law still more general. He found that the deflections of the planets from uniform rectilineal motion were all directed to the sun; and that the simultaneous deflections were inversely proportional to the squares of the distances from that body. Thus was established a physical law of vast extent. But further observation showed him, that the motion of every body of the solar system was compounded of an original motion of projection, combined with a deflection towards every other body; and that the simultaneous deflections were proportional to the quantity of matter in the body towards which they were directed, and to the reciprocal of the square of the distance from it. Thus was the law made still more general. But he did not stop here. He compared the deflection of the moon in her orbit with the simultaneous deflection of a stone thrown from the hand, and describing a parabola; and he found that they followed the same law, that is, that the deflection of the moon in a second, was to that of the stone in the same time, as the square of the stone's distance from the centre of the earth to the square of the moon's distance from it. Hence he concluded, that the deflection of a stone from a straight line was just a particular instance of the deflections which took place throughout the whole solar system. The deflection of a stone is one of the indications it gives of its being *gravis* or heavy, whence he calls it *gravitation*. He therefore expresses the physical law which obtains throughout the whole solar system by saying that "every body *gravitates* to every other body; and the gravitations are proportional to the quantity of matter in that other body, and inversely proportional to the square of the distance from it."

Thus we see how the arrangement of the celestial phenomena terminated in the discovery of physical laws; and that the expression of this arrangement is the law itself. Since the fall of a heavy body is one instance of the physical law, and since this fall is considered by all as the effect of its *weight*, and this weight is considered as the cause of the fall, the same cause is assigned for all the deflections observed in the solar system, and all the matter in it is found to be under the influence of this cause, or to be heavy; and thus his doctrine has been denominated the *system of universal gravitation*.

Philosophers have gone farther, and supposed that gravity is a power, property, or quality, residing in all the bodies of the solar system. Sir Isaac Newton does not expressly say so, at least in that work where he gives an account of these discoveries. He contents himself with the immediate consequence of the first axiom in natural philosophy, viz. that every body remains in a state of rest, or of uniform rectilineal motion, unless affected by some moving force. Since the bodies of the solar system are neither in a state of rest, nor of uniform rectilineal motion, they must be considered as so affected; that is, that there operates on every one of them a moving force, directed towards all the others, and having the proportions observed in the deflection.

Other philosophers have endeavoured to show, that this general fact, detected by Sir Isaac Newton, is included in another still more general, viz. that every body moves which is impelled by another body in motion. They assert, that all the bodies of the solar system are continually impelled by means of a fluid which they call *ether*, which is moving in all places, and in all directions, or in circular vortices, and hurries along with it the planets and all heavy bodies. It would seem that the familiarity of motion produced by impulse, at least in those instances in which our own exertions are most employed, has induced philosophers to adopt such notions; perhaps, too, they are influenced by an obscure and indistinct notion affixed to the term action, as applied to changes in the material world, and which has given rise to an axiom, "that a body cannot act at a distance, or where it is not," and thus have thought themselves obliged to look out for an immediate and contiguous agent in all these phenomena.

But the philosophers who profess to be most scrupulous in their adherence to the rules of philosophic discussion deny the legitimacy of this pretended investigation of causes, saying that this doctrine is in direct opposition to the procedure of the mind in acquiring the knowledge of causes. Since the fact of impulse is not really observed in the celestial deflections, nor in the motions of heavy bodies, the law cannot be inferred. They say that it is not even necessary to show that the phenomena of the celestial motions are unlike the phenomena of impulse, although this can be done in the completest manner. It is enough that neither the fluid nor the impulse are observed; and therefore they are in the right when they assert that there is inherent in, or accompanies, all the bodies of the system, a power by which they deflect to one another. The debate is foreign to our present purpose, which is only to show how the observation and arrangement of phenomena terminate in the discovery of their causes, or the discovery of the powers or properties of natural substances. This is a task of great difficulty, as it is of great importance.

Causes of the difficulty of philosophical investigation.

There are two chief causes of this difficulty. 1. In most of the spontaneous phenomena of nature there is a complication of many events, and some of them escape our observation. Attending only to the most obvious or remarkable, we conjoin these only in our imagination, and are apt to think these the concomitant events in nature, the proper indication of the cause, and the subjects of this philosophical relation, and to suppose that they are always conjoined by nature. Thus it was thought that there resided in a vibrating chord a power by which the sensation of sound was excited, or that a chord had a sounding quality. But it appears clearly from observation that there is an inconceivable number of events interposed between the vibration of the chord and the sensitive affection of our ear; and therefore, that sound is not the effect of the vibration of the chord, but of the very last event of this series; and this is completely demonstrated by showing that the vibration and the sound are not necessarily connected, because they are not always connected, but require the interposition of air or of some other elastic body. These observations show the necessity of the most accurate and minute observation of the phenomena, that none of those intermediate events may escape us, and we be thus exposed to the chance of imaginary connections between events which are really far asunder in the procedure of nature. As the study has improved, mistakes of this kind have been corrected; and philosophers have become careful to make their trains of events under one name as short as possible. Thus, in medicine, a drug is no longer considered as a specific remedy for the disease which is sometimes cured when it has been used, but is denominated by its most immediate operation on the animal frame; it is no longer called a febrifuge, but a sudorific.

2. When many natural powers combine their influence in a spontaneous phenomenon of nature, it is frequently very difficult to discover what part of the complicated effect is the effect of each; and to state those circumstances of similarity which are the foundation of a physical law, or entitle us to infer the agency of any natural power. The most likely method for insuring success in such cases is to get rid of this complication of event, by putting the subject into such a situation that the operation of all the known powers of nature shall be suspended, or so modified as that we may perfectly understand their effects. We can thus appreciate the effects of such as we could neither modify nor suspend, or we can discover the existence of a new law, the operation of a new power.

Experimental philosophy.

This, which is called *making an experiment*, is, of all, the most effectual way of advancing in the knowledge of nature, and it has been called *Experimental Philosophy*. It seems, however, at first sight, in direct opposition to the procedure of nature in forming general laws. These are formed by induction from multitudes of individual facts, and must be affirmed to no greater extent than the induction on which they are founded. Yet it is a matter of fact, a physical law of human thought, that one simple, clear, and unequivocal experiment gives us the most complete confidence in the truth of a general conclusion from it to every similar case. Whence this anomaly? It is not an anomaly or contradiction of the general maxim of philosophical investigation, but the most refined application of it. There is no law more general than this, that "Nature is constant in all her operations." The judicious and simple form of our experiment insures us in the complete knowledge of all the circumstances of the event. Upon this supposition, and upon this alone, we consider the experiment as the faithful representative of every possible case of the conjunction. This will be more minutely considered afterwards.

Theory or explanation of subordinate phenomena.

The last branch of philosophical occupation is the explanation of subordinate phenomena. This is nothing more than the referring any particular phenomenon to that class in which it is included; or, in the language of philosophy, it is the pointing out the general law, or that general fact of which the phenomenon is a particular instance. Thus the feeling of the obligations of virtue is thought to be explained when it is shown to be a particular case of that regard which every person has for his dearest interests. The rise of water in pumps is explained when we show it to be a particular case of the pressure of fluids, or of the air. The general law under which we show it to be properly arranged is called the *principle* of the explanation, and the explanation itself is called the *theory* of the phenomenon. Thus Euler's explanation of the lunar irregularities is called a theory of the lunar motions on the principle of gravitation. This may be done either in order to advance our own knowledge of nature, or to communicate it to others. If done with the first view, we must examine the phenomenon minutely, and endeavour to detect every circumstance in it, and thus discover all the known laws of nature which concur in its production; we then appreciate the operation of each, according to the circumstances of its exertion; we then combine all these, and compare the result with the phenomenon. If they are similar, we have explained the phenomenon. We cannot give a better example than Franklin's explanation of the phenomena of thunder and lightning.

If we explain a phenomenon from known principles, we proceed synthetically from the general law already established and known to exert its influence in the present instance. We state this influence both in kind and degree, according to the circumstances of the case; and having combined them, we compare the result with the phenomenon, and show their agreement, and thus it is explained. Thus, because all the bodies of the solar system mutually gravitate, the moon gravitates to the sun as well as to the earth, and is continually, and in a certain determinate manner, deflected from that part which she would describe did she gravitate only to the earth. Her motion round the earth will be retarded during the first and third quarters of her orbit, and accelerated during the second and fourth. Her orbit and her period will be increased during our winter, and diminished during our summer. Her apogee will advance, and her nodes will recede; the inclination of her orbit will be greatest when the nodes are in syzigee, and least when they are in quadrature; and all these variations will be in certain precise degrees. Then we show that all these things actually obtain the lunar motions, and they are considered as explained.

Fundamental proposition of philosophical discussion.

This summary account of the object and employment in all philosophical discussion is sufficient for pointing out its place in the circle of the sciences, and will serve to direct us to the proper methods of prosecuting it with success. Events are its object; and they are considered as connected with each other by causation, which may therefore be called the philosophical relation of things. The following may be adopted as the fundamental proposition on which all philosophical discussion proceeds, and under which every philosophical discussion or discovery may be arranged:—"Every change that we observe in the state or condition of things *is considered by us* as an effect, indicating the agency, characterizing the kind, and determining the degree of its *inferred* cause."

As thus enounced, this proposition is evidently a physical law of human thought. It may be enounced as a necessary and independent truth, by saying that every change in the state and condition of things *is an effect*, &c. And accordingly it has been so enounced by Dr Reid;[1] and its title to this denomination has been abundantly supported by him. But we have no occasion to consider it as possessing this quality. We are speaking of philosophy, which is something contingent, depending on the existence and constitution of an intellectual being such as man; and, in conformity to the view which we have endeavoured to give of human knowledge in the subjects of philosophical relation, it is quite sufficient for our purpose that we maintain its title to the rank of an universal law of human thought. This will make it a first principle, even although it may not be a necessary truth.

All the proof necessary for this purpose is universality of fact; and we believe this to be without exception. We are not to expect that all mankind have made, or will ever make, a formal declaration of their opinion; but we may venture to say that all have made it, and continually do make it, virtually. What have the philosophers of all ages been employed about except the discovery of the causes of those changes that are incessantly going on? "Nil turpius physico," says Cicero, "quam fieri sine causa quidquam dicere." Human curiosity has been directed to nothing so powerfully and so constantly as to this. Many absurd causes have been assigned for the phenomena of the universe; but no set of men have ever said that they happened without a cause. This is so repugnant to all our propensities and instincts, that even the atheistical philosophers, who, of all others, would have profited most by the doctrine, have never thought of advancing it. To avoid so shocking an absurdity, they have rather allowed that chance, and the concourse of atoms, are the causes of the beautiful arrangements of nature. The thoughtless vulgar are no less solicitous than the philosophers to discover the cause of things; and the poet expresses the natural and instinctive passion of all men when he says,

> Felix qui potuit rerum cognoscere causas.

And this anxiety is not to nourish, but to get rid of superstitious fears; for thus

> ...... metus omnes, et inexorabile fatum
> Subjecit pedibus, strepitumque Acherontis avari.

Had men never speculated, their conduct alone gives sufficient evidence of the universality of the opinion. The whole conduct of man is regulated by it, nay, almost wholly proceeds upon it, in the most important matters, and where experience seems to leave us in doubt; and to act otherwise, as if any thing whatever happened without a cause, would be a declaration of insanity. Dr Reid has beautifully illustrated this truth, by observing, that even a child will laugh at you if you try to persuade him that the top, which he misses from the place where he left it, was taken away by nobody. You may persuade him that it was taken away by a fairy or a spirit; but he believes no more about this nobody than the master of the house, when *he* is told that nobody was the author of any piece of theft or mischief. What opinion would be formed, says Dr Reid, of the intellects of the juryman, on a trial for murder by persons unknown, who should say that the fractured skull, the watch and money gone, and other like circumstances, might possibly have no cause? He would be pronounced insane or corrupted.

This ciple trove by M Hum

We believe that Mr Hume is the first author who has ventured to call the truth of this opinion in question; and even he does it only in the way of mere possibility. He acknowledges the generality of the opinion, and he only objects to the foundation of this generality; and he objects to it merely because it does not quadrate with his theory of belief, and therefore it may happen that some men may have no such opinion. But it must be observed on this occasion, that the opinion of a philosopher is of no greater weight in a case like this than that of a ploughboy. If it be a first principle, directing the opinions and actions of all, it must operate on the minds of all. The philosopher is the only person who may chance to be without it; for it requires much labour, and long habits resolutely maintained, to warp our natural sentiments; and experience shows us that they may be warped if we are at sufficient pains. It is also worthy of remark, that this philosopher seems as much under the influence of this law as ordinary mortals. It is only when he is aware of its not tallying with his other doctrines that his scruples appear. Observe how he speaks when off his guard: "As to those impressions which arise from the senses, their ultimate cause is, in my opinion, perfectly inexplicable by human reason; and it will always be impossible to decide with certainty whether they arise immediately from the object, are produced by the creative power of the mind, or are derived from the Author of our being."

---

[1] Essays on the Intellectual Powers of Man.

Amongst these alternatives he never thought of their not being derived from any cause. But it is not enough to show that this is a physical law of the human mind. We have assumed it as a first principle, the foundation of a whole science, and therefore not included in or derived from any thing more general. Mr Hume's endeavours to prove that it is not a necessary truth, show with sufficient evidence that most attempts to derive it in the way of argument are *petitiones principii;* a thing very commonly met with in all attempts to prove first principles. It cannot be proved by induction of facts that every event has a cause, because induction always supposes an observed fact or event. Now in by far the greater number of events the causes are unknown. Perhaps in no event whatever do we know the real cause, or that power or energy which, without any intervention, produces the effect. No man can say that, in the simplest event which he ever observed, he was fully apprised of every circumstance which concurred to its production. We suppose that no event in nature can be adduced more simple than the motion of a suspended glass ball when gently struck by another glass ball; and we imagine that most of our readers will say that they perfectly see every thing which happens in this phenomenon. We believe, too, that most of our readers are of opinion that a body is never put in motion but by the impulse of another, except in the cases of animal motion; and that they are disposed to imagine that magnets put iron in motion, and that an electrified body moves another, by means of an interposed though invisible fluid somehow circulating round them. Now we must inform such readers, that unless the stroke has been very smart, so smart indeed as to shatter the glass balls, the motion of the suspended ball was produced without impulse; that is, the two balls were not in contact during the stroke, and the distance between them was not less than the nine thousandth part of an inch, and probably much greater. We must say farther, that it is not certain that even the violent stroke, such as would shatter them to pieces, is enough to bring them into real contact.

Unless, therefore, our readers are willing to allow that the suspended ball was put in motion by a repulsive force inherent in one or both balls, they must acknowledge that they do not fully know all the circumstances of this so simple phenomenon, or all the train of events which happen in it; and therefore they are reduced to the necessity of supposing, although they do not see it, an intervening fluid or matter, by the immediate action of the adjoining particles of which the motion is produced.

View of Bacon's Philosophy.

This being the case in the simplest phenomenon that we can pitch upon, what shall we say of the numberless multitudes which are incomparably more complex. Must we not acknowledge that the efficient causes, even in the vulgar sense of the word, the immediately preceding events, are unknown, because the conjunctions are not observed; and therefore it cannot be said that it is from experimental induction that this truth gains universal belief. Experience, so far from supporting it as a direct proof, seems rather the strongest argument against it; for we have no experiment of unquestionable authority but the narrow circle of our own power exerted upon our thoughts and actions. And even here there are perhaps cases of change where we cannot say with certainty that we perceive the efficient cause. Nothing seems to remain, therefore, but to allow that this physical law of human judgment is instinctive, a constituent of the human soul, a first principle, and incapable of any other proof than the appeal to the feelings of every man.

Causes not observed, but inferred from the phenomena.

Simply to state, that every change is considered as an effect, is not giving the whole characters of this physical law. The cause is not always, perhaps never, observed, but it is inferred from the phenomena. The inference is therefore in every instance dependent on the phenomenon. The phenomenon is to us the language of nature. It is therefore the sole indication of the cause and of its agency; it is the indication of the very cause, and of no other. The observed change therefore characterizes the cause, and marks its kind. This is confirmed by every word of philosophical language, where, as has already been observed, the names of the inferred powers of nature are nothing but either abbreviated descriptions of the phenomena, or terms which are defined solely by such descriptions. In like manner, the phenomenon determines the cause in a particular degree, and in no other; and we have no immediate measure of the degree of the cause but the phenomenon itself. We take many measures of the cause, it is true; but on examination they will be found not to be immediate measures of the cause, but of the effect. Assuming gravitation as the cause of the planetary deviations from uniform rectilineal motion, we say that the gravitation of the moon is but $\frac{1}{3600}$th part of the gravitation of a stone thrown from the hand; but we say this only from observing that the deflection of the stone is three thousand six hundred times greater than the simultaneous deflection of the moon. In short, our whole knowledge of the cause is not only founded on our knowledge of the phenomenon, but it is the same. This will be found a remark of immense consequence in the prosecution of philosophical researches; and a strict attention to it will not only guard us against a thousand mistakes into which the reasoning pride of man would continually lead us, but will also enable us fully to detect may egregious and fatal blunders made in consequence of this philosophical vanity. Nothing can be more evident than that, whenever we are puzzled, it would be folly to continue groping amongst those obscure beings called causes, when we have their prototypes, the phenomena themselves, in our hands.

Such is the account which may be given of philosophy, the study of the works of God, as related by causation. It is of vast extent, reaching from an atom to the glorious Author of the universe, and contemplating the whole connected chain of intelligent, sensitive, and inanimate beings. The philosopher makes use of the descriptions and arrangements of the natural historian as of mighty use to himself in the beginning of his career, confiding in the uniformity of nature, and expecting that similarity in the quiescent properties of things will be accompanied by some resemblances in those more important properties which constitute their mutual dependencies, linking them together in a great and endlessly-ramified chain of events.

We have endeavoured to ascertain with precision the peculiar province of philosophy, both by means of its object and its mode of procedure. After this it will not require many words to point out the methods for prosecuting the study with expedition and with success. The rules of philosophizing, which Newton premises in his account of the

View of Bacon's Philosophy.

planetary motions, which he so scrupulously followed, and with a success which gives them great authority, are all in strict conformity to the view we have now given of the subject.

The chief rule of philosophizing explained.

The chief rule is, that similar causes are to be assigned to similar phenomena. This is indeed the source of all our knowledge of connected nature; and without it the universe would only present to us an incomprehensible chaos. It is by no means, however, necessary to enjoin this as a maxim for our procedure; it is an instinctive propensity of the human mind. It is absolutely necessary, on the contrary, to caution us in the application of this propensity. We must be extremely confident in the certainty of the resemblance before we venture to make any inference. We are prone to reason from analogy; the very employment is agreeable, and we are ever disposed to embrace opportunities of engaging in it. For this reason we are satisfied with very slight resemblances, and eagerly run over the consequences, as if the resemblance were complete; and our researches frequently terminate in falsehood.

This propensity to analogical reasoning is aided by another equally strong, and equally useful when properly directed; we mean the propensity to form general laws. This is in fact a propensity to discover causes, which is equivalent to the establishing of general laws. It appears in another form, and is called a love of or taste for simplicity; and this is encouraged or justified, as agreeable to the uniformity and simplicity of nature. "Natura semper sibi similis et consona," says Newton. "Frustra fit per plura, quod fieri potest per pauciora," says another. The beautiful, the wise economy of nature, are phrases in every body's mouth; and Newton enjoins us to adopt no more causes than are sufficient to explain the phenomena. All this is very well, and is true in its own degree; but it is too frequently the subterfuge of human vanity and self-love. This inordinate admiration of the economy and simplicity of nature is generally conjoined with a manifest love of system, and with the actual production of some new system, where from one general principle some extensive theory or explanation is deduced and offered to the world. The author sees a sort of resemblance between a certain series of phenomena and the consequences of some principle, and thinks the principle adequate to their explanation. Then, on the authority of the acknowledged simplicity of nature, he roundly excludes all other principles of explanation; because, says he, this principle is sufficient, "et frustra fit per plura," &c. We could point out many instances of this kind in the writings of perhaps the first mathematician and the poorest philosopher of this century; where extensive theories are thus cavalierly exhibited, which a few years' examination have shown to be nothing but analogies, indistinctly observed, and, what is worse, inaccurately applied.

A true cause explained.

To regulate these hazardous propensities, and thus to keep philosophers in the right path, Newton inculcates another rule, or rather gives a modification of this injunction of simplicity. He enjoins that no cause shall be admitted but what is real. His words are, that "no causes shall be admitted but such as are true, and sufficient to account for the phenomena." We apprehend that the meaning of this rule has been mistaken by many philosophers, who imagine that by true he means causes which really exist in nature, and are not mere creatures of the imagination. We have met with some who would boggle at the doctrines of Aristotle respecting the planetary motions, viz. that they are carried along by conducting intelligent minds, because we know of none such in the universe; and who would nevertheless think the doctrine of the Cartesian vortices deserving of at least an examination, because we see such vortices exist, and produce effects which have some resemblance to the planetary motions, and have justly rejected them, solely because this resemblance has been very imperfect. We apprehend Newton's meaning by these words is, that no cause of any event shall be admitted, or even considered, which we do not know to be actually concurring or exerting some influence in that very event. If this be his meaning, he would reject the Cartesian vortices, and the conducting spirits of Aristotle, for one and the same reason; not because they were not adequate to the explanation, nor because such causes do not exist in nature, but because we did not see them anyhow concerned in the phenomenon under consideration. We neither see a spirit nor a vortex, and therefore need not trouble ourselves with inquiring what effects they would produce. Now we know that this was his very conduct, and what has distinguished him from all philosophers who preceded him, though many, by following his example, have also been rewarded by similar success. This has procured to Newton the character of the modest philosopher; and modest his procedure may, for distinction's sake, be called, because the contrary procedure of others did not originate so much from ignorance as from vanity. Newton's conductor in this was not modesty, but sagacity, prudence, caution, and, to say it purely, it was sound judgment.

For the bonds of nature, the supposed philosophical causes are not observed; they are only inferred from the phenomena. When two substances are observed, and only when they are observed to be connected in any series of events, we infer that they are connected by a natural power; but when one of the substances is not seen, but fancied, no law of human thought produces any inference whatever. For this reason alone Newton stopped short at the last fact which he could discover in the solar system, that all bodies were deflected to all other bodies, according to certain regulations of distance and quantity of matter. When told that he had done nothing in philosophy, that he had discovered no cause, and that to merit any praise he must show how this deflection was produced, he said that he knew no more than he had told them; that he saw nothing causing this deflection, and was contented with having discovered it so exactly, that a good mathematician could now make tables of the planetary motions as accurate as he pleased, and with hoping in a few years to have every purpose of navigation and of philosophical curiosity completely answered; and he was not disappointed. And when philosophers on all sides were contriving hypothetical fluids and vortices which would produce these deflections, he contented himself with proving the total inconsistency of these explanations with the mechanical principles acknowledged by their authors; showing that they had transgressed both parts of his rule, their causes neither being real, nor sufficient for explaining the phenomena. A cause is sufficient for explaining a phenomenon only when its legitimate consequences are perfectly agreeable to these phenomena.

This d trine fo ed in re son.

Newton's discoveries remain without any diminution or change; no philosopher has yet advanced a step farther. But let not the authority, nor even the success, of Newton, be our guide. Is his rule founded in reason? It surely is. For if philosophy be the only interpretation of nature's language, the inference of causes from the phenomena, a fancied or hypothetical phenomenon can produce nothing but a fanciful cause, and can make no addition to our knowledge of real nature.

Danger hypoth

All hypotheses therefore must be banished from philosophical discussion as frivolous and useless, administering to vanity alone. As the explanation of any appearance is nothing but the pointing out the general fact, of which this is a particular instance, a hypothesis can give no explanation; knowing nothing of cause and effect but the conjunction of two events, we see nothing of causation where one of the events is hypothetical. Although all the legitimate consequences of a hypothetical principle should be perfectly similar to the phenomenon, it is extremely dangerous to assume this principle as the real cause. It is illogical to make use of the economy of nature as an argument for the truth of any hypothesis; for, if true, it is a physical truth, a matter of fact, and true only to the extent in which it is observed; and we are not entitled to say that it is so one step farther, therefore not in this case till it be observed. But the proposition that nature is so economical, is false; and it is astonishing that it has been so lazily acquiesced in by the readers of hypotheses; for it is not the authors who are deceived by it; they are generally led by their own vanity. Nothing is more observable than the prodigious variety of nature. That the same phenomena may be produced by different means, is well known to the astronomers, who must all grant that the appearances of motion will be precisely the same whether the earth moves round the sun like the other planets, or whether the sun with his attendant planets moves round the earth; and that the demonstration of the first opinion is had from a fact totally unconnected with all the deflections, or even with their causes; for it may be asserted, that Dr Bradley's discovery of the aberration of the fixed stars, in consequence of the progressive motion of light, was the first thing which put the Copernican system beyond question; and even this is still capable of being explained in another way. The Author of nature seems to delight in variety; and there cannot be named a single purpose on which the most inconceivable fertility in resource is not observed. It is the most delightful occupation of the curious mind and the sensible heart to contemplate the various contrivances of nature in accomplishing similar ends.

As a principle, therefore, on which to found any maxim of philosophical procedure, this is not only injudicious, because imprudent and apt to mislead, but as false, and almost sure to mislead. In conformity to this observation, it must be added, that nothing has done so much harm in philosophy as the introduction of hypotheses.

Authors have commonly been satisfied with very slight resemblances, and readers are easily misled by the appearances of reasoning which these resemblances have countenanced. The ancients, and above all Aristotle, were much given to this mode of explanation. and have filled philosophy with absurdities. The slightest resemblances were with them sufficient foundations of theories. It has been by very slow degrees that men have learned caution in this respect; and we are sorry to say that we are not yet cured of the disease of hypothetical systematizing, and to see attempts made by ingenious men to bring the frivolous theories of antiquity again into credit. Nay, modern philosophers, even of the greatest name, are by no means exempted from the reproach of hypothetical theories. Their writings abound in ethers, nervous fluids, animal spirits, vortices, vibrations, and other invisible agents. We may affirm that all these attempts may be shown to be either unintelligible, fruitless, or false. Either the hypothesis has been such that no consequence can be distinctly drawn from it, on account of its obscurity and total want of resemblance to any thing we know; or the just and legitimate consequences of the hypothesis are inconsistent with the phenomena. This is remarkably the case in the hypotheses which have been introduced for the explanation of the mechanical phenomena of the universe. These can be examined by accurate science, and the consequences compared without any mistake; and nothing else but a perfect agreement should induce us even to listen to any hypothesis whatever.

It may be here asked, Whether, in the case of the most perfect agreement, after the most extensive comparison, the hypothesis should be admitted? We believe that this must be left to the feelings of the mind. When the belief is irresistible, we can reason no more. But as there is no impossibility of as perfect an agreement with some other hypothesis, it is evident that it does not convey an irrefragable title to our hypothesis. It is said, that such an agreement authorizes the reception of the hypothetical theory, in the same manner as we must admit that to be the true cipher of a letter which will make perfect sense of it. But this is not true. In deciphering a letter we know the sounds which must be represented by the characters, and that they are really the constituents of speech; but in hypothetical explanations the first principle is not known to exist; nay, it is possible to make two ciphers, each of which shall give a meaning to the letter. Instances of this are to be seen in treatises on the art of deciphering.

We conclude our criticism on hypothetical explanations with this observation, that it is *impossible* that they can make any addition to our knowledge. In every hypothesis we thrust in an intermediate event between the phenomenon and some general law; and this event is not seen, but supposed. Therefore, according to the true maxims of philosophical investigation, we give no explanation; for we are not by this means enabled to assign the general law in which this particular phenomenon is included. Nay, the hypothesis makes no addition whatever to our list of general laws; for our hypotheses must be selected, in order to tally with all the phenomena. The hypothesis therefore is understood only by and in the phenomena, and it must not be made more general than the phenomena themselves. The hypothesis gives no generalization of facts. Its very application is founded on a great coincidence of facts; and the hypothetical fact is thrust in between two which we really observe to be united by nature. The applicability, therefore, of the hypothesis is not more extensive than the similarity of facts which we observe, and the hypothetical law is not more general than the observed law. Let us then throw away entirely the hypothetical law, and insert the observed one in our list of general laws; it will be in different language from the hypothetical law, but it will express the same facts in nature.

On what occasions hypotheses may be useful.

It is in experimental philosophy alone that hypotheses can have any just claim to admission; and here they are not admitted as explanations, but as conjectures serving to direct our line of experiments. Effects only appear; and by their appearance, and the previous information of experience, causes are immediately ascertained by the perfect similarity of the whole train of events to other trains formerly observed. Or they are suggested by more imperfect resemblances of the phenomena; and these suggestions are made with stronger or fainter evidence, according as the resemblance is more or less perfect. These suggestions do not amount to a confidential inference, and only raise a conjecture. Wishing to verify or overturn this conjecture, we have recourse to experiment; and we put the subject under consideration in such a situation that we can say what will be the effect of the conjectural cause if real. If this tallies with the appearance, our conjecture has more probability of truth, and we vary the situation, which will produce a new set of effects of the conjectured cause, and so on. It is evident that the probability of our conjecture will increase with the increase of the conformity of the legitimate effects of the supposed cause with the phenomena, and that it will be entirely destroyed by one disagreement. In this way conjectures have their great use, and are the ordinary means by which experimental philosophy is improved. But conjectural systems are worse than nonsense, filling the mind with false notions of nature, and generally leading us into a course of improper conduct when they become principles of action. This is acknowledged even by the abettors of hypothetical systems themselves when employed in overturning those of their predecessors, and establishing their own; witness the successive maintainers of the many hypothetical systems in medicine,

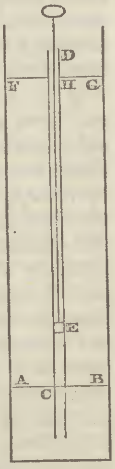
View of Bacon's Philosophy.

which have had their short-lived course within these two last centuries. Let every person, therefore, who calls himself a philosopher, resolutely determine to reject all temptations to this kind of system-making, and let him never consider a composition of this kind as any thing better than the amusement of an idle hour.

True mode of philosophical procedure.

After these observations, it cannot require much discussion to mark the mode of procedure which will insure progress in all philosophical investigations. The sphere of our intuitive knowledge being very limited, we must be indebted for the greatest part of our intellectual attainments to our rational powers, and it must be deductive. In the spontaneous phenomena of nature, whether of mind or body, it seldom happens that the energy of that natural power, which is the principle of explanation, is so immediately connected with the phenomenon that we can see the connection at once. Its exertions are frequently concealed, and in all cases modified, by the joint exertions of other natural powers; hence the particular exertion of each must be considered apart, and their mutual connection traced out. It is only in this way that we can discover the perhaps long train of intermediate operations, and also see in what manner and degree the real principle of explanation concurs in the ostensible process of nature.

In all such cases it is evident that our investigation (and investigation it most strictly is) must proceed by successive steps, conducted by the sure hand of logical method. To take an instance from the material world, let us listen to Galileo whilst he is teaching his friends the cause of the rise of water in a pump. He says that it is owing to the pressure of the air. This is his principle; and he announces it in all its extent. All matter, says he, is heavy, and in particular air is heavy. He then points out the connection of this general principle with the phenomenon. Air being heavy, it must be supported; it must lie and press on what supports it; it must press on the surface AB of the water in the cistern surrounding the pipe CD of the pump; and also on the water C within this pipe. He then takes notice of another general principle which exerts its subordinate influence in this process. Water is a fluid; a fluid is a body the parts of which yield to the smallest impression, and, by yielding, are easily moved amongst themselves; and no little parcel of the fluid can remain at rest unless it be equally pressed in every direction, but will recede from that side where it sustains the greatest pressure. In consequence of this fluidity, known to be a property of water, if any part of it is pressed, the pressure is propagated through the whole; and if not resisted upon every side, the water will move to that side where the propagated pressure is not resisted. All these subordinate or collateral propositions are supposed to be previously demonstrated or allowed. Water, therefore, must yield to the pressure of the air, unless pressed by it upon every side, and must move to that side where it is not withheld by some opposite pressure. He then proceeds to show, from the structure of the pump, that there is no opposing pressure on the water in the inside of the pump. "For," says he, "suppose the piston thrust down till it touches the surface of the water in the pipe; suppose the piston now drawn up by a power sufficient to lift it, and all the air incumbent on it; and suppose it drawn up a foot or fathom, there remains now nothing that I know of to press on the surface of the water. In short," says he, "gentlemen, it appears to me that the water in the pump is in the same situation that it would be in were there no air at all, but water poured into the cistern to a height AF; such, that the column of water FABG presses on the surface AB as much as the air does. Now, in this case, we know that the water at C is pressed upwards with a force equal to the weight of a column of water having the section of the pipe for its base and CH for its height. The water below C, therefore, will be pressed up into the pipe CD, and will rise to G, so that it is on a level with the external water FG; that is, it will rise to H. This is a necessary consequence of the weight and pressure of the incumbent column FABG, and the fluidity of the water in the cistern. Consequences perfectly similar must necessarily follow from the weight and pressure of the air; and therefore, upon drawing up the piston from the surface C of the water with which it was in contact, the water must follow it till it attain that height which will make its own weight a balance for the pressure of the circumambient air. Accordingly, gentlemen, the Italian plumbers inform me that a pump will not raise water quite fifty palms; and from their information I conclude, that a pillar of water fifty palms high is somewhat heavier than a pillar of air of the same base, and reaching to the top of the atmosphere."



View- Bacon Philo- phy.

The syn- thetica metho

Thus is the phenomenon explained. The rise of the water in the pump is shown to be a particular case of the general fact in hydrostatics, that fluids in communicating vessels will stand at heights which are inversely as their densities, or that columns of equal weights are in equilibrio. This way of proceeding is called arguing *a priori*, or the synthetical method. It is founded on just principles; and the great progress which we have made in the mathematical sciences by this mode of reasoning shows to what length it may be carried with irresistible evidence. It has long been considered as the only inlet to true knowledge; and nothing was allowed to be known with certainty which could not be demonstrated in this way to be true. Accordingly logic, or the art of reasoning, which was also called the art of discovering truth, was nothing but a set of rules for successfully conducting this mode of argument.

Under the direction of this infallible guide, it is not surely unreasonable to expect that philosophy should make sure progress towards perfection; and as we know that the brightest geniuses of Athens and of Rome were for ages solely occupied in philosophical researches in every path of human knowledge, it is equally reasonable to suppose that the progress has not only been sure, but great. We have seen that the explanation of an appearance in nature is nothing but the arrangement of it into that general class in which it is comprehended. The class has its distinguishing mark, which, when it is found in the phenomenon under consideration, fixes it in its class, there to remain for ever an addition to our stock of knowledge. Nothing can be lost any other way but by forgetting it; and the doctrines of philosophers must be stable, like the laws of nature.

We have seen, however, that the very reverse of all this is the case; that philosophy has but very lately emerged from worse than total darkness and ignorance; that what passed under the name of philosophy was nothing but systems of errors, if systems they could be called, which were termed doctrines, delivered with the most imposing apparatus of logical demonstration, but belied in almost every instance by experience, and affording us no assistance in the application of the powers of nature to the purposes of life. Nor will this excite much wonder in the mind of the enlightened reader of the present day, who reflects on the use that in this dialectic process was made of the categories, and the method in which those categories were formed. From first principles so vague in themselves, and so gratuitously assumed, ingenious men might deduce many different conclusions, all equally erroneous; and that this was actually done, no surer evidence can be given, than that hardly a lifetime elapsed when the whole system of doctrines which had captivated the minds of the most penetrating was oftener than once exploded and overturned by of n's so- y.

another system, which flourished for a while, and then was supplanted by a third, which shared the same fate. Here was an infallible proof of their error, for instability is incompatible with truth.

It is allowed by all that this has been the case in those branches of study at least which contemplate the philosophical relations of the material world; in astronomy, in mechanical philosophy, in chemistry, in physiology, in medicine, in agriculture. It is also acknowledged, that in the course of less than two centuries we have acquired much knowledge respecting these very subjects, call it philosophy, or by what name you will; so much more conformable to the natural course of things, that the deductions made from it by the same rules of the synthetic method are more conformable to fact, and therefore better fitted to direct our conduct and improve our powers. It is also certain that these bodies of doctrine which go by the name of philosophical systems have much more stability than in ancient times; and though sometimes in part superseded, they are seldom or never wholly exploded.

This cannot perhaps be affirmed with equal confidence respecting those speculations which have our intellect or propensities for their object: And we have not perhaps attained such a representation of human nature as will bear comparison with the original, nor will the legitimate deductions from such doctrines be of much more service to us for directing our conduct than those of ancient times; for whilst we observe this difference between these two general classes of speculations, we may remark, that it is conjoined with a difference in the manner of conducting the study. We have proceeded according to the old Aristotelian method when investigating the nature of mind; yet we see the material philosophers running about, passing much of their time away from books in the shop of the artisan, or in the open fields engaged in observation, labouring with their hands, and busy with experiments. But the speculatist on the intellect and the active powers of the human soul seems unwilling to be indebted to any thing but his own ingenuity, and his labours are confined to the closet. In the first class, we have met with something like success, and we have improved many arts; in the other, it is to be feared that we are not much wiser, or better, or happier, for all our philosophical attainments.

Here, therefore, must surely have been some great and fatal mistake. There has indeed been a material defect in our mode of procedure, in the employment of this method of reasoning as an inlet to truth. The fact is, that philosophers have totally mistaken the road of discovery, and have pretended to set out in their investigation from the very point where this journey should have terminated.

The Aristotelian logic, the syllogistic art, that art so much boasted of as the only inlet to true knowledge, and the only means of discovery, is in direct opposition to the ordinary procedure of nature, by which we every day, and in every action of our lives, acquire knowledge and discover truth. It is not the art of discovering truth; it is the art of communicating knowledge, and of detecting error: it is nothing more than the application of this maxim; "Whatever is true of a whole class of objects, is true of each individual of that class." This is not a just account of the art of discovering truth, nor is it a complete account of the art of reasoning. Reasoning is the producing of belief; and whatever mode of argumentation invariably and irresistibly produces belief, is reasoning. The ancient logic supposes that all the first principles are already known, and that nothing is wanted but the application of them to particular facts. But were this true, the application of them, as we have already observed, can hardly be called a discovery. But it is not true; and the fact is, that the first principles are generally the chief objects of our research, and that they have come into view only now and then, as it were by accident, and never by the labour of the logician. He indeed can tell us whether we have been mistaken; for if our general principle be true' it must influence every particular case. If, therefore, it be false in any one of these, it is not a true principle. And it is here that we discover the source of that fluctuation which is so much complained of in philosophy. The authors of systems give a set of consecutive propositions logically deduced from a first principle, which has been hastily adopted, and has no foundation in nature. This does not hinder the amusement of framing a system from it, nor this system from pleasing by its symmetry; and it takes a run: but when an officious follower thinks of making some use of it, which requires the comparison with experience and observation, they are found totally unlike, and the whole fabric must be abandoned as unsound; and thus the successive systems were continually pushing out their predecessors, and presently met with the same treatment.

View of Bacon's Philosophy.

How was this to be remedied? The ratiocination was seldom egregiously wrong; the syllogistic art had ere now attained a degree of perfection which left little room for improvement, and was so familiarly understood by the philosophical practitioners, that they seldom committed any great blunders. Must we examine the first principles? This was a task quite new in science; and there were hardly any rules in the received systems of logic to direct us to the successful performance of it. Aristotle, the sagacious inventor of those rules, had not totally omitted it; but, in the fervour of philosophical speculation, he had made little use of them. His fertile genius never was at a loss for first principles, which answered the purpose of verbal disquisition, without much risk of being belied on account of its dissimilitude to nature; for there was frequently no prototype with which his systematic doctrine could be compared. His enthusiastic followers found abundant amusement in following his example; and philosophy, being no longer in the hands of men acquainted with the world, conversant in the great book of nature, was now confined almost entirely to recluse monks, equally ignorant of men and of things. But curiosity was awakened, and the men of genius were fretted as well as disgusted with the disquisitions of the schools, which one moment raised expectations by the symmetry of composition, and the next moment blasted them by their inconsistency with experience. They saw that the best way was to begin *de novo;* to throw away the first principles altogether, without exception or examination, and endeavour to find out new ones which should stand the test of logic; or, in other words, should in every case be agreeable to fact.

The method of induction pointed out by nature.

Philosophers began to reflect, that under the unnoticed tuition of kind nature we have acquired much useful knowledge. It is therefore highly probable that her method is the most proper for acquiring knowledge, and that by imitating her manner we shall have the like success. We are too apt to slight the occupations of children, whom we may observe continually busy turning every thing over and over, putting them into every situation, and at every distance. We excuse it, saying that it is an innocent amusement; but we should rather say with an ingenious philosopher (Dr Reid), that they are most seriously and rationally employed; they are acquiring the habits of observation, and, by merely indulging an undetermined curiosity, they are making themselves acquainted with surrounding objects; they are struck by similitudes, and amused with mere classification. If some new effect occurs from any of their little plays, they are eager to repeat it. When a child has for the first time tumbled a spoon from the table, and is pleased with its jingling noise upon the floor, if another lie within its reach, it is sure to share the same fate. If the child be indulged in this diversion, it will repeat it with a greediness that deserves our attention. The very first eager repetition shows a confidence in the constancy of natural operations, which we can hardly ascribe wholly to experience; and its keenness to repeat the experiment shows the interest which it takes in the exercise of this most useful propensity. It is beginning the study of nature; and its occupation is the same with that of a Newton computing the motions of the moon by his sublime theory, and comparing his calculus with observation. The child and the philosopher are equally employed in the contemplation of a similarity of event, and are anxious that this similarity shall return. The child, it is true, thinks not of this abstract object of contemplation, but throws down the spoon again to have the pleasure of hearing it jingle. The philosopher suspects that the conjunction of events is the consequence of a general law of nature, and tries an experiment where this conjunction recurs. The child is happy, and eager to enjoy a pleasure which to us appears highly frivolous; but it has the same foundation with the pleasure of the philosopher, who rejoices in the success of his experiment; and the fact, formerly a trifle to both, now acquires importance. Both go on repeating the experiment, till the fact ceases to be a novelty to either; the child is satisfied, and the philosopher has now established a new law of nature.

Such, says this amiable philosopher, is the education of kind nature, who from the beginning to the end of our lives makes the play of her scholars their most instructive lessons, and has implanted in our mind the curiosity and the inductive propensity by which we are enabled and disposed to learn them. The exercise of this inductive principle, by which nature prompts us to infer general laws from the observation of particular facts, gives us a species of logic new in the schools, but as old as human nature. It is certainly a method of discovery; for by these means general principles, formerly unknown, have come into view.

Induction a just logic.

Induction is a just and rational logic; for it is founded on, and indeed is only the habitual application of, this maxim, that "Whatever is true with respect to every individual of a class of events, is true of the whole class." This is just the inverse of the maxim upon which the Aristotelian logic wholly proceeds, and is of equal authority in the court of reason. Indeed, the expression of the general law is only the abbreviated expression of every particular instance. This new logic, therefore, or the logic of induction, must not be considered as subordinate to the old system, or founded upon it. In fact, the use and legitimacy of the Aristotelian logic is founded on the inductive: All animals are mortal; all men are animals; therefore all men are mortal. This is no argument to any person who chooses to deny the mortality of men; for even although he acknowledges his animal nature, he will deny the major proposition.

It is beside our purpose to show how a point so general, so congenial to man, and so familiar, remained so long unnoticed, although the disquisition is curious and satisfactory. It was not till within these two centuries that the increasing demand for practical knowledge, particularly in the arts, made inquisitive men see how useless and insufficient was the learning of the schools in any road of investigation which was connected with life and business; and observe that society had received useful information chiefly from persons actually engaged in the arts which the speculatists were endeavouring to illustrate; and that this knowledge consisted chiefly of experiments and observations, the only contributions which their authors could make to science.

The *Novum Organum* of Bacon, which points out the true method of forming a body of real and useful knowledge, namely, the study of nature in the way of description, observation, and experiment, is undoubtedly the noblest present that science ever received. It may be considered as the grammar of nature's language, and is a counterpart to the logic of Aristotle; not exploding it, but making it effectual. (B. B. B.)

PHILOSTRATUS, Flavius, was an ancient Greek author. Eusebius calls him an Athenian, because he taught at Athens; but Eunapius and Suidas always speak of him as a Lemnian; and he himself hints, in his Life of Apollonius, that when he was young he used to reside at Lemnos. He frequented the schools of the sophists; and he mentions his having heard Damianus of Ephesus, Proclus Naucratitas, and Hippodromus of Larissa. This seems to prove that he lived in the reign of the Emperor Severus, from 193 to 212, when those sophists flourished. He afterwards became known to Julia Augusta, the wife of Severus, and was one of those learned men whom this philosophical empress had continually about her. It was by her command that he wrote his celebrated Life of Apollonius Tyanensis, as he relates himself in the same place where he informs us of his connections with that learned lady. Philostratus, as Cyril observes, endeavours to represent Apollonius as a wonderful and extraordinary person, rather to be admired and adored as a god, than to be honoured or considered as a mere man. Hence Eunapius, in the preface to his Lives of the Sophists, says that the proper title of that work should have been, The Coming of a God to Men; and Hierocles, in his book against the Christians, called Philalethes, and which was refuted by Eusebius in a work still extant, amongst other things instituted a comparison between Apollonius and Jesus Christ. It has always been supposed that Philostratus composed his work with a view to discredit the miracles and doctrines of our Lord, by setting up other miracles and other doctrines against them; and this supposition may be true: but that Apollonius was really an impostor and magician may not be so certain. He may, for ought we know, have been a wise and excellent person; and it is remarkable that Eusebius, though he had the worst opinion of the history of Philostratus, says nothing unfavourable of Apollonius. He concluded that that history was written to oppose the history of Jesus; and the use which the ancient infidels made of it justifies his opinion: but he draws no information from it with regard to Apollonius. It would have been improper to do so, since the sophistical and affected style of Philostratus, the sources whence he owns that his materials were drawn, and, above all, the absurdities and contradictions with which he abounds, plainly show that his history was nothing but a collection of fables, either invented, or at least embellished, by himself.

The works of Philostratus, however, have engaged the attention of some critics of the first class. Grævius intended to have given a correct edition of them, as appears from the preface of Meric Casaubon to a dissertation upon an intended edition of Homer, printed at London in 1658, 8vo. So also had Bentley, who designed to add a new Latin version of his notes; and Fabricius says that he saw the first sheet of Bentley's edition printed at Leipzig in 1691. Both these designs, however, were dropped. But a very exact and beautiful edition was at length published at Leipzig, 1709, in folio, by Olearius, professor of the Greek and Latin languages in that university; a man who has proved himself perfectly qualified for the work he undertook, and shown all the judgment, learning, and industry, which are required in an excellent editor.

At the end of the Life of Apollonius, there are ninety-five letters which go under his name. They are not, however, believed to be his, the style of them being very affected, and like that of a sophist, whilst they bear in other respects all the marks of a forgery. Philostratus says that he saw a collection of the Letters of Apollonius in Hadrian's library at Antium, but had not inserted them all amongst these. They are short, and have in them little else than moral sentences. The Lives of the Sophists contain many things which are to be met with nowhere else. The Heroics of Philostratus are only a dialogue between a vintner of the Thracian Chersonesus and a Phœnician, in which the former draws characters of Homer's heroes, and represents several things differently from that poet; and this is done upon the faith of Protesilaus's ghost, who had lately visited his farm, not far from the tomb of this hero. Olearius conjectures, with much probability, that Philostratus's design in this dialogue was secretly to criticise some things in Homer, which he durst not do openly, on account of the great veneration then paid to him, and for fear of the odium which Zoilus and others had incurred by censuring him too freely. The images are elegant descriptions and illustrations of some ancient paintings and other particulars relating to the fine arts, to which Olearius has subjoined the description of some statues by Callistratus, for the same reason that he subjoined Eusebius's book against Hierocles to the Life and Letters of Apollonius, namely, because the subjects of these respective works are related to each other. The last piece is a collection of Philostratus's Letters; but some of these, though it is not easy to determine which, were written by a nephew of Philostratus, of the same name, as were also the last eighteen in the book of images. This is the reason why the title runs not *Philostrati*, but *Philostratorum quæ supersunt omnia*. There were many persons of the name of Philostratus amongst the ancients; and there were many other works of the Philostratus here recorded, but no others are extant except those we have mentioned.

PHILOXENUS, a celebrated dithyrambic poet, a native of the island of Cythera, flourished B. C. 398, being contemporary with Timotheus and Telestes, and died at the age of sixty, B. C. 380. He was a son of Euletidas, and, when Cythera was taken by the Lacedæmonians, he was carried off as a slave. He was sold to Hegesylus, and on his death was bought by the poet Melanippides, by whose instruction he seems to have profited. He was devoted to the pleasures of the table, and became a great favourite of the elder Dionysius. Amongst various anecdotes told of him, it is said that Dionysius once repeated some of his own poetry to him, and asked his opinion of it, when the poet boldly told him that it was mere trash. The tyrant ordered him to prison, but at the solicitation of his friends released him the following day, and invited him to supper. He again repeated some poetry; but when Philoxenus was asked his opinion, he simply said, "Order me again to prison;" and arose, in expectation of being led away; but the tyrant was amused at the idea, and forgave him. Philoxenus, however, took an early opportunity of leaving Syracuse, and retired to Tarentum, which no solicitation of the tyrant could induce him to leave. According to another statement, he was so long confined in prison, that he had time to write a poem entitled Cyclops, which is said to have been one of the finest of his productions. Alexander the Great was a great admirer of the dithyrambics of Philoxenus and Telestes.

PHILTER, or PHILTRE (*philtrum*), in *Pharmacy* or *Chemistry*, a strainer. This term is also used for a drug or preparation, which, it is pretended, will excite love. The word is formed from the Greek φιλεω, *I love*, or φιλος, *lover;* because philters were given by the Greeks and Romans to excite love. Many grave authors believe the reality of these philters, and allege various facts in confirmation of their sentiments.

PHILYRA, in fabulous history, was one of the Oceanides, whom Saturn met in Thrace. The god, to escape from the vigilance of Rhea, changed himself into a horse, and by Philyra had a son half a man and half a horse, called Chiron. Philyra was so ashamed of having given birth to such a monster, that she entreated the gods to change her nature; and she was accordingly metamorphosed into a tree, called by her name amongst the Greeks.

PHINEHAS, or, as the Jews pronounce it, PINEHAS, was the son of Eleazar, and the grandson of Aaron. He was the third high priest of the Jews, and discharged this office from the year of the world 2571 till towards the year 2590. He appears in Scripture chiefly as distinguished by pious zeal for the faithful discharge of his duty, and for the divine glory. Two of his actions are commemorated as more particularly worthy of notice in this respect. The former of these events occurred during the high priesthood of his father Eleazar, and whilst he himself was second priest. The circumstances connected with it, and of which a full account is given by Moses (Numb. xxv. 7, ff.), were briefly these: Balaam, a famous soothsayer, having been brought by Balak, king of Moab, to curse the Israelites, but having by a mysterious influence been compelled to bless them, willing nevertheless to please his patron, and to earn "the wages of unrighteousness," suggested to the king the expedient of seducing the Israelites to idolatry, as the most likely mode of withdrawing from them the protection and favour of God. The expedient unhappily proved successful. Attracted by the license that prevailed at the celebration of the heathen festivals, the people of Israel joined in the sacrifices, and indulged in the loose and immoral practices of the Moabites. As an expression of the divine indignation against this conduct, God, in addition to a destroying plague which he sent amongst the people, commanded the judges of Israel to "slay every one his men that were joined to Baal-peor." To this command Phinehas was the first to render obedience. One of the princes of Israel, a man of great influence in the tribe of Simeon, Zimri by name, having audaciously, in this madness of sinful indulgence, conveyed a Moabitish female of high rank through the very midst of the camp of the Israelites, thereby offering outrage to the virtue and piety of those who were lamenting over the transgressions of the people, insulting in the most direct manner the majesty of God, and ostentatiously uttering defiance of the threatened punishment, Phinehas, stirred with a holy indignation, rushed from the midst of those who in horror and consternation had beheld the daring offence, and, following the guilty prince to his tent, transfixed him and his paramour in the midst of their licentious indulgence, and killed them both with one blow. For this act of valour, decision, and zeal, the plague was removed, and Phinehas was rewarded by having renewed to him that "covenant of peace," "the covenant of an everlasting priesthood," which God had on former occasions made with Noah, Abraham, and others distinguished for piety and zeal. Some have erroneously supposed that the blessing conferred upon Phinehas was the perpetuation in his family of the high priesthood of the Jews, and they have been not a little puzzled to account for the fact, that this office nevertheless passed out of his family after the death of Eli, at a period not very far removed from that here referred to. The mistake, however, must be obvious to all who have observed carefully the language of Scripture in regard to what is called God's covenant. By that term is designated the covenant of grace, "the everlasting covenant," which, the apostle tells us, was sealed with the blood of Christ (Heb. xiii. 20). This covenant God made with Adam after the fall; and he renewed it with particular individuals, in token of his approbation of their conduct, from time to time, until it was consummated in Christ; and it was by such a renewal of it with Phinehas that he expressed his commendation of the zeal which that individual showed in the case above related. With this, his occupying the place of high priest had no connection, as to that he succeeded by right of birth on the death of his father.

The other memorable action of Phinehas, in which he showed his zeal for the Lord, is recorded in Josh. xxii. 9–34. This was when the Israelites who were beyond Jordan had raised upon the banks of this river a vast heap of earth in the form of an altar. Those on the other side, fearing that they were going to forsake the Lord, and set up another religion, deputed Phinehas and other chief men amongst them to go and inform themselves of the reason of erecting this monument. But when they had found that it was in commemoration of their union and common original, Phinehas took occasion to praise the Lord, saying, "We perceive that the Lord is among us, because ye have not committed this trespass against the Lord."

We do not exactly know the time of the death of Phinehas. But as he lived after the death of Joshua, and before the first servitude under Chushan-rishathaim, during the time that there were neither kings nor judges in the land, and every one did that which was right in his own eyes (Judges, xvii. 6, xviii. 1, xxi. 24), his death is placed about the year of the world 2590. It was under his pontificate that the story of Micah happened, as also that of the tribe of Dan, when they made a conquest of Laish; and the enormity which was committed upon the wife of the Levite of the mountain of Ephraim (Judges, xx. 28). Phinehas's successor in the high priesthood was Abiezar, or Abishuah.

The Rabbin allow a very long life to Phinehas. There are some who believe that he lived to the time of the high priest Eli, or even to that of Samson. Others will have it that he was the same as Eli, or rather as the prophet Elias, which would still prolong his life for several ages.

PHLEBOTOMY, the opening of a vein with a proper sharp-edged and pointed instrument, to let out a certain quantity of blood, either for the preservation or recovery of a person's health. See SURGERY.

PHLEGON, a Greek historian, was a native of Tralles, in Lydia, and the freedman of the Emperor Hadrian (A. D. 117–138); and he is said to have published under his own name some works which were really the production of the emperor. He was the author of a history or chronicle, in sixteen books, which ended A. D. 141; and the loss of this work is the more to be regretted, as it would have probably furnished us with some curious information respecting the early times of the Christian church. A small fragment, entitled *De Olympiis*, on the origin and institution of the Olympic games, still remains; and in this work he notices the eclipse or wonderful darkness which occurred at the death of our Saviour. We have also two other works; *De Longævis libellus*, in which he mentions a certain Faustus, aged 136, who was presented to the emperor; and *De Rebus Mirabilibus liber*, a collection of popular stories, and prodigies performed at Delphi, which are narrated by those who had been eye-witnesses. These fragments have been frequently published, but the edition of Bast (Halle, 1822, 8vo) includes all the valuable annotations of his predecessors.

PHLOGISTON, a term employed by chemists to denote a principle which was supposed to enter into the composition of various bodies. The bodies which were thought to contain it in the largest quantity are such as are inflammable; and the property which these substances possess of being susceptible of inflammation was thought to depend upon this principle, so that it was sometimes called the Principle of Inflammability. Inflammation, according to this doctrine, was the separation of this principle, or phlogiston, from the other matter which composed the combustible body. As its separation was always attended with the emission of light and heat, some chemists thence concluded that it was light and heat combined with other matter in a peculiar manner, or that it was some highly elastic and very subtile matter, upon certain modifications of which heat and light depended. Another class of bodies which were supposed to contain phlogiston were the metals; and the chemists supposed that the peculiar lustre of the metals depended on this principle. Of this they thought themselves convinced by the evidence of their senses in two ways; first, because by exposing a metal to the action of a long-continued heat, it lost its metallic lustre, and was converted into an earthy-like substance called *calx metallicus*, or oxide; and, secondly, because by mixing this oxide with any inflammable substance whatever, and subjecting the mixture to certain operations, the inflammable matter disappeared, and the metal was restored to its former condition and lustre, without suffering much diminution in quantity, especially if the processes had been conducted with care and attention.

This fact relative to the metals was thought to be a full demonstration of itself, independently of other proofs which were brought to support the doctrine. These were, that a combustible body, by the act of inflammation, that is, by the dissipation of its phlogiston in the form of heat and light, was converted into a body which was no longer combustible, but which might have its property of combustibility restored to it again by mixing the incombustible remains with any kind of inflammable matter, and submitting the mixture to certain processes. In this way the body was restored to its former state of inflammability.

They were also at some pains to prove that the phlogiston, or the principle of inflammability, was the same in all inflammable bodies, and also in the metals. This identity of phlogiston they thought to be evident from the fact, that the calx of a metal might be restored to its metallic state, or that the remains after the combustion of a combustible body might be restored to its original state of combustibility by the addition of any inflammable body whatever, taken either from the animal, the vegetable, or the mineral kingdoms.

These and several other facts were brought to prove, not only the existence of phlogiston, but its effects in mixture with other substances; and the objections which were made against the doctrine were removed with wonderful ingenuity. The chief objection against it was, that if the inflammation of a combustible body, or the conversion of a metal into calx, depends upon the dissipation or extrication of phlogiston, then it must follow, that the remains of a combustible body after inflammation, and the calx of the metal, must be less than the matter from which they were produced. But this is contrary to fact, for when we collect with care all the vapour into which the purest inflammable bodies are converted by combustion, these incombustible remains are much heavier than the inflammable body from which they were produced, and the calx into which a metal is converted by long exposure to the action of heat is heavier than the metal from which it was produced. This consideration made several people doubt of the truth of the doctrine; but the objection was removed by saying, that phlogiston was so subtile, as not only to have no weight, but to possess an absolute levity; and that when it was taken from an absolutely heavy body, that body must, by losing so much absolute levity, become heavier, in the same manner as the algebraists say that a positive quantity is augmented by the subtraction of a negative quantity. This sophism satisfied the minds of most of the chemists, especially those who were algebraists.

The opinion that phlogiston was heat and light somehow combined with other matter, was proved, not only by the fact that heat and light were emitted from a combustible body during its combustion, but from the reduction of certain metallic calces to the original metallic state again, at least in some degree, by simple exposure to heat and light. The white calx of silver, for instance, when exposed in closely-sealed glass vessels to the light and heat of the sun, resumes a black tinge, and is in part restored to its metallic lustre, without any addition whatever; but then this restoration, like the others above mentioned, is attended with a loss of weight.

Besides constituting the principal portion of inflammable bodies and metals, phlogiston was thought to be the cause of colour in all vegetable and animal substances. This was concluded from the fact of plants growing white when defended from the action of the sun's rays, and having their green colour restored by fresh exposure to the light; and so far did the chemists suffer themselves to be deceived, that they actually thought the green colouring matter, which they extracted from fresh plants by certain chemical processes, to be an inflammable substance. But a very material objection was made to this argument. If plants owe their colour to phlogiston imparted by the sun's rays, why do the sun's rays destroy vegetable colours which are exposed to them? We know that the sun's rays are very effectual in diminishing the lustre of cloth dyed with vegetable colours, and in bleaching or taking out various stains from linen and other substances. All this, however, was removed by saying, that the sun's rays possessed different powers on living and on dead vegetable matter, and that the living vegetables had the power of absorbing phlogiston from the sun's rays, which dead vegetable matter had not.

Since the existence of phlogiston, as a chemical principle in the composition of certain bodies, has now been fully proved to be false, we shall not trouble our readers with any further observations on it, except to add, that although the chemists were satisfied with the proofs they gave of its reality, they were never able to exhibit it in a separate state, or show it in a pure form, unmixed with other matter.

From the time of Sir Isaac Newton till the middle of the eighteenth century, no real improvement was made in scientific chemistry; and the progress this science has made since that period is owing to the important discovery of the existence of heat in a state of composition with other matter. Heat thus combined loses its activity, or becomes insensible, just in the same way as any other active substance loses its apparent qualities in composition. Acids, for example, when combined in a certain proportion with substances for which they have strong attraction, as alkalies or absorbent earths, lose all their obvious acid qualities, and the compound turns out mild, and totally conceals the acid which it contains. In a similar manner, heat, when combined in certain proportions with other matter, loses its sensible qualities, and the compound conceals the heat which it contains. Heat, in this combined state, was denominated by its ingenious discoverer, Dr Black, *latent;* and it was found to be very abundant in the atmosphere, which owes its existence as an elastic fluid to the quantity of latent heat that it contains. After this discovery was made, Dr Crawford, considering that air was absorbed by a burning body, concluded that the heat which appears in the combustion of a combustible body, is the heat that had before existed in the air which was consumed by the burning body. M. Lavoisier and others, prosecuting this inquiry, found that the combustible body, whilst it is burning, unites with the basis of the air, and that the heat which the air contained, and which was the cause of the air existing in the state of air, is expelled. This absorption of the basis of the air by the burning body, and the reduction of this basis to a solid form, accounts for the increase of weight which a body acquires by burning; or, in other words, gives a reason why the matter into which a combustible body is converted by combustion, is heavier than the body from which it was produced. The same absorption of air is observable when a metal is converted into a calx, and the additional weight of the calx is found to be precisely equal to the weight of the air absorbed during the calcination. On these principles, therefore, we now explain the phenomena in a much more satisfactory manner than by the supposition of phlogiston, or a principle of inflammability.

PHOCÆA, the most northern of the cities of Ionia, was situated on the coast, about two hundred stadia from Smyrna. It was founded by a colony of Phocians, led by two Athenians, Philogenes and Damon, and was not admitted into the Ionian confederacy till it had received, from Teos and Erythræ, kings of the race of the Codridæ. Its citizens are said to have been the first amongst the Greeks who extended their voyages to great distances; in fact, the Adriatic, Tuscany, and even Tartessus, were visited in pursuit of commercial speculations. After the conquest of Crœsus, Cyrus sent his general Harpagus to reduce the Greek cities of Ionia, and the Phocæans abandoned their city rather than submit to the Persian yoke, B. C. 544. Some of them returned, but the greater part eventually settled in Italy, and founded the city of Velia. Phocæa, however, must still have continued to exist, as it furnished three ships in the Ionian revolt. Livy describes the city as standing at the bottom of a bay, and as being of an oblong shape. It enclosed a space of two miles and a half in length, and then contracted on both sides into a narrow wedge-like form, which place they called Lampter, or the lighthouse. It had two excellent harbours; the one towards the south was called Naustathmos, and the other was situated close to Lampter. It was taken and plundered by the Romans in the war against Antiochus. Phocæa founded Massilia, and Attalia in Corsica. The site is still called *Palaio Fokia.*

PHOCION, a very celebrated Athenian general, was descended from a family which at no time had been particularly distinguished in the political transactions of their country. He was born B. C. 402, and died B. C. 317, at the age of eighty-five. His early years were spent under the direction of Plato and Xenocrates, and his subsequent career showed that he had profited by their instruction. His aspect was forbidding, though his disposition was mild and gentle. It was remarked, that he was never seen to laugh or to weep. He commenced his military career under Chabrias, and gained so much influence with that general that he directed many of his proceedings. The victory at Naxos, B. C. 376, was in a great measure due to his prudence and military talents; nor was he less distinguished as a statesman and orator. He was quick in perception, and ready in debate, so that Demosthenes feared him more than any other orator, and is said to have called him the *Hatchet.* Phocion was aware of the true position of his country, knowing that she could no longer maintain that predominating influence which she had possessed during the last century. Peace was therefore the true policy of Athens, and he at all times advocated such a course of conduct. Yet, though his sense of the true interests of his country led him to be the promoter of peace, he was at all times ready to assist with his military talents. He commanded in the expedition, B. C. 350, against Eubœa, and gained the battle of Jamynæ. When Philip king of Macedonia laid siege to Byzantium, and the cities along the coast, Phocion relieved these cities from all danger, and compelled Philip to retire. At the head of his army he endured all the fatigues of the lowest of his soldiers; and when he appeared more warmly dressed than usual, the soldiers used to consider it the sign of a severe winter. He was a man of the strictest integrity; and, at a time when few of the orators and statesmen of Athens were able to resist the temptation of enriching themselves at the expense of their country, Phocion remained poor, and refused all the offers of the Macedonian kings. He was, of course, opposed to the policy of Demosthenes, and employed all his influence to thwart his measures. In the troubles which followed the death of Alexander, he was favourable to the party of Antipater; and when Polysperchon re-established the popular form of government, Phocion was seized, and being brought before an assembly, Phocis.

composed chiefly of slaves and strangers, he was condemned to die. He was put to death in his eighty-fifth year.

PHOCIS, a country of Greece, contained between Bœotia in the east and Locris in the west, but extending formerly from the *Sinus Corinthiacus* on the south to the Sea of Eubœa on the north, and, according to Dionysius, as far as Thermopylæ; though it was reduced afterwards to narrower dimensions. The *Phocenses* were the people of Phocis, and *Phocicus* was the epithet; thus *Bellum Phocicum* means the sacred war which the Thebans and Philip of Macedonia carried on against them for plundering the temple at Delphi, and by which Philip paved the way to the sovereignty of all Greece. The greatest length of Phocis was from north to south, that is, from 38. 45. to 39. 20., or about thirty-five miles; but it was very narrow from east to west, not extending to thirty miles, that is, from 23. 10. to 23. 40. at the widest, but about twenty-three miles towards the Corinthian bay, and still narrower towards the north. This country is generally allowed to have taken its name from Phocus the son of Ornytion, a native of Corinth; but having been soon afterwards invaded by the Eginetæ, under the conduct of another Phocus, the son of Eacus king of Enopia, the memory of the first insensibly gave way to that of the second.

In Phocis there were several very celebrated mountains, such as Cythæron, Helicon, and Parnassus. Cythæron was consecrated to the muses, as were also the other two, and it was consequently much celebrated by the poets. Both it and Helicon contend with Parnassus for height and magnitude. There were no remarkable rivers in Phocis except the Cephisus, which runs from the foot of Parnassus northwards, and empties itself into the Pindus, which was near the boundary of the kingdom. It had several very considerable cities, such as Cirrha, Crissa, and Antecyra, which, according to Ptolemy, were situated on the sea coasts; and Pythia, Delphi, Daulis, Elatia, Ergosthenia, and Baulia, which were inland towns. Elatia was the largest and richest after Delphi.

Deucalion was king of that part of Phocis which lies near Parnassus, at the time when Cecrops flourished in Attica; but the Phocians afterwards formed themselves into a commonwealth, governed by their general assemblies, the members of which were chosen from amongst themselves, and changed as often as occasion required. Of the history of the Phocians but little is known until the time of the holy war, of which the following account is given in the Ancient Universal History.

"The Phocians having presumed to plough the territories of the city of Cirrha, consecrated to the Delphic god, were summoned by the other Grecian states before the court of the Amphictyons, where a considerable fine was imposed upon them for their sacrilege. They refused to pay it, on pretence that it was too large; and at the next assembly their dominions were adjudged confiscated to the use of the temple. This second sentence exasperated the Phocians still more; who, at the instigation of one Philomelus, or, as he is called by Plutarch, Philomedes, seized upon the temple, plundered it of its treasure, and held the sacred depositum for a considerable time. This second crime occasioned another assembly of the Amphictyons, the result of which was a formal declaration of war against the Phocians. The quarrel being become more general, the several states took part in it, according to their inclinations or interest. Athens, Sparta, and some others of the Peloponnesians, declared for the Phocians; and the Thebans, Thessalians, Locrians, and other neighbouring states, against them. A war was commenced with great fury on both sides, and styled *the holy war*, which lasted ten years; during which the Phocians, having hired a number of foreign troops, made an obstinate defence, and would in all probability have held out much longer had not Philip of Macedon given the finishing stroke to their total defeat and punishment. The war being ended, the grand council assembled again, and imposed an annual fine of sixty talents upon the Phocians, to be paid to the temple, and continued till they had fully repaired the damage it had sustained from them; and, till this reparation should be made, they were excluded from dwelling in walled towns, and from having any vote in the grand assembly. They did not, however, continue long under this heavy sentence. Their known bravery made their assistance so necessary to the rest, that they were glad to remit it; after which remission they continued to behave with their usual courage and resolution, and soon obliterated their former guilt."

Phocyli
||
Phœni

PHOCYLIDES, a Greek poet, was a native of Miletus, in Ionia, and flourished B. C. 544, being the contemporary of Theognis. He was the author of some epic poems and elegies; but, of all his works, only a poem (*Carmen Nutheticon*), of two hundred and seventeen verses, has been preserved. As it is only alluded to by an ancient scholiast on Nicander, there is some doubt if it be really the production of Phocylides, as none of the passages quoted by Plato, Aristotle, Strabo, and other writers, are to be found in any part of this poem. It is published in all the editions of the *Sententiæ* of Theognis; but the most valuable one is that by J. A. Schier, with a Latin translation, and learned annotations, Leipzig, 1751, 8vo.

PHŒBUS, one of the names applied by the ancient mythologists to the Sun, Sol, or Apollo.

PHŒNICIA, or more properly PHŒNICE, the ancient name of a country situated between the thirty-fourth and thirty-sixth degrees of north latitude, being bounded by Syria on the north and east, by Judæa on the south, and by the Mediterranean on the west. How it obtained its name is not certainly known. Some derive it from one Phœnix; and others from the Greek word *phœnix*, signifying a *palm* or *date*, as that tree abounded in the country. Some suppose that Phœnice was originally a translation of the Hebrew word *Edom*, from the Edomites who fled thither in the days of David. By the contraction of the word *Canaan* it was also called *Chna*, and anciently *Rhabbothin* and *Colpitis*. The Jews commonly named it *Canaan;* though some part of it, at least, was known to them by the name of *Syrophœnice*. Bochart tells us, that the most probable etymology is *Phene Anak*, the descendants of Anak. Such were the names peculiar to this small country, though Phœnice was sometimes extended to all the maritime countries of Syria and Judæa, and Canaan to that of the Philistines, and even of the Amalekites. On the contrary, all these names were superseded by those of Palestine and Syria.

There is some disagreement amongst authors respecting the northern limits of this country. Ptolemy states the river Eleutherus as the boundary of Phœnice to the north; but Pliny, Mela, and Stephanus, place it in the island of Aradus, to the northward of that river. Strabo observes, that some considered the river Eleutherus as the boundary of Seleucis, on the side of Phœnice and Cœlesyria. On the coast of Phœnice, and south of the river Eleutherus, stood the cities of Simyra, Orthosia, Tripolis, Botrys, Byblus, Palæbyblus, Berytus, Sidon, Sarepta, Tyrus, and Palætyrus.

According to Ptolemy, Phœnice extended even beyond Mount Carmel; for that geographer places in Phœnice not only Ecdippa and Ptolemais, but Sycaminum and Dæra, which are situated to the southward of that mountain. But these towns, properly speaking, belonged to Palestine. We will not take upon us to mark out the bounds of the midland Phœnice. Ptolemy reckons in it the towns of Arca, Palæbyblus, Gabala, and Cæsaria Paniæ. This province was considerably extended in the early times of Christianity, when, being considered as a province of Syria, it included not only Damascus, but also Palmyra.

The Phœnicians were governed by kings; and their territory, small as it was, included several kingdoms, namely, those of Sidon, Tyre, Aradus, Berytus, and Byblus. In this particular they imitated and adhered to the primitive government of their forefathers, who, like the other Canaanites, were under many petty princes, to whom they allowed the sovereign dignity, reserving to themselves the natural rights and liberties of mankind. Of their civil laws no remnant has been preserved.

With regard to religion, the Phœnicians were the most gross and abominable idolaters. The Baal-berith, Baalzebub, and Baal-samen, mentioned in Scripture, were some of the Phœnician gods; as were Moloch, Ashtaroth, and Thammuz, also mentioned in the sacred writings. The word *Baal*, in itself an appellative, was no doubt applied to the true God, until he rejected it on account of its being so much profaned by the idolaters. The name was not appropriated to any particular deity amongst the idolatrous nations, but was common to many; it was generally imagined, however, that one supreme God presided over all the rest. Amongst the Phœnicians this deity was named *Baal-samen*, but the Hebrews would have called him *Baal-shemim*, or the God of heaven. In all probability this was also the principal Carthaginian deity, although his Punic name is unknown. Many religious rites of the Carthaginians have been handed down to us by the Greek and Roman writers; but they all bestowed the names of their own gods upon those of the Carthaginians, a circumstance which leads us to a knowledge of the correspondence between the characters of the Phœnician and the European deities. The principal deity of Carthage was, according to Diodorus Siculus, Chronos or Saturn; and the sacrifices offered up to him were children of the best families. We also learn, that the Carthaginians had a brazen statue or colossus of this god, the hands of which were extended in the act of receiving, and bent downwards in such a manner that the child laid thereupon immediately fell down into a hollow where there was a fiery furnace. It is added, that this inhuman practice seemed to confirm a tradition handed down to the Greeks from remote antiquity, that Saturn devoured his own children.

The goddess Cœlestis, or Urania, was held in the highest veneration by the Carthaginians. She is supposed to have been the same with the queen of heaven mentioned in Jeremiah, or the Juno Olympia of the Greeks. According to Hesychius, the same word, in the Punic language, was applied both to Juno and Venus; nay, the ancient Greeks frequently confound Juno, Venus, and Diana or the moon, which is to be attributed to the Egyptians and Phœnicians, from whom they received their system of religion, and who in the most ancient times appear to have had but one name for them all. Besides these there were several other deities, who were worshipped amongst the Phœnicians, particularly those of Tyre, and consequently amongst the Carthaginians. These were Jupiter, Apollo, Mars, and Bacchus. Jupiter was worshipped under the name of *Belus* or *Baal;* to him they addressed their oaths; and his name they placed at the head of their treaties. Apollo or the Sun went either by this name simply, or by others of which it formed a part.

The Carthaginian superstition, however, was not confined to these deities alone. They worshipped the fire, the air, and the other elements, and had a multitude of local gods. Nay, they paid divine honours to the spirits of their heroes, and even to men and women whilst yet in life; and in this adoration Hannibal had for some time a share, notwithstanding the infamous conduct which his countrymen showed towards him at last. In order to worship these gods with more convenience, the Carthaginians had a kind of portable temples. These were covered chariots, in which were small images representing their favourite deities, and which were drawn by oxen. They served also as a kind of oracle, and their responses were understood by the motion impressed upon the vehicle. The tabernacle of Moloch is supposed to have been a machine of this kind; and it is not probable that the whole was derived from the tabernacle of the Jews in the wilderness.

Besides all the deities above mentioned, we find another, named the *Dæmon* or *Genius* of Carthage, which is mentioned in the treaty made by Philip of Macedonia and Hannibal. What this deity was we know not; but it may be observed, that the pagan world in general believed in the existence of dæmons, or intelligences who had a kind of middle nature between gods and men, and to whom the administration of the world was in a great measure committed. Hence it is no wonder that they should have received religious honours; for when once mankind were possessed with the opinion that they were the ministers of the gods, and trusted with the dispensation of their favours, as well as the infliction of their punishments, it is natural to suppose that they would be desirous of making their addresses to these beings.

Much has been said of their arts, sciences, and manufactures; but as all that we find concerning them is couched in general terms, we cannot enter into particulars. The Sidonians, under which denomination we comprehend the Phœnicians in general, were a people of most happy genius. They were from the beginning addicted to philosophical exercises of the mind; insomuch that a Sidonian, by name Moschus, taught the doctrine of atoms before the Trojan war, and Abomenus of Tyre puzzled Solomon by the subtilty of his questions. Phœnice continued to be one of the seats of learning, and in later times both Tyre and Sidon produced their respective philosophers; namely, Boethus and Diodatus of Sidon, Antipater of Tyre, and Apollonius of the same place, who gave an account of the writings and disciples of Zeno. As to their manufactures, the glass of Sidon, the purple of Tyre, and the fine linen they wove, were the products of their own country, and their own invention; and for their extraordinary skill in working metals, in hewing timber and stone, and their perfect knowledge of what was solid, great, and ornamental in architecture, we need only remind the reader of the large share which they had in erecting and decorating the temple at Jerusalem under their king Hiram. Their fame for taste, design, and ingenious invention, was such, that whatever was elegant, great, or pleasing, whether in apparel, in vessels, or in toys, was distinguished by way of excellence by the epithet of Sidonian.

The Phœnicians were likewise celebrated merchants, navigators, and planters of colonies in foreign parts. As merchants, they may be said to have engrossed all the commerce of the western world; as navigators, they were the boldest, the most experienced, and the greatest discoverers of ancient times, and for many ages they had no rivals. In planting colonies they exerted themselves so much that, considering their territory was little more than the slip of land situated between Mount Lebanon and the sea, it is surprising how they could furnish such supplies of people, and not wholly depopulate their native country.

It is generally supposed that the Phœnicians were induced to deal in foreign commodities by their neighbourhood to the Syrians, who were perhaps the most ancient of those who carried on a considerable and regular trade with the nations farther to the east. And this conjecture appears at least probable; for their own territory was but small, and little able to afford any considerable exports, if we except manufactures; but that their manufactures were considerable until they began to turn all the channels of trade into their own country, it is difficult to believe. In Syria, which was a large country, they found store of productions of the natural growth of the soil, whilst many choice and useful commodities were imported from the East. Thus, having a safe coast, with convenient harbours on one side, and excellent materials for ship-building on the other; perceiving how acceptable many commodities which Syria furnished would be in foreign parts, and being stimulated by the example of the Syrians; they turned all their thoughts to trade and navigation, and by an uncommon application soon eclipsed their masters in that art.

It were in vain to discourse of the Edomites who fled hither in David's time, or to inquire why Herodotus supposed that the Phœnicians came from the Red Sea. That some of the Edomites fled into this country in the days of David, and that they were a trading people, is very evident; but what improvements they brought with them into Phœnice it is hard to say, and it is not less difficult to ascertain their numbers. In all probability they brought with them a knowledge of the Red Sea, and of the southern parts of Arabia, Egypt, and Ethiopia, and by their information made the Phœnicians acquainted with those coasts; and by these means the latter were enabled to undertake voyages to those parts, for Solomon, and Pharaoh-Necho, king of Egypt.

Their whole thoughts were employed about schemes for advancing their commerce. They affected no empire but that of the sea, and appeared to aim at nothing but the peaceable enjoyment of their trade. This they extended to all the known parts they could reach; to the British Islands, commonly understood by the Cassiterides; to Spain, and other places in the ocean both within and without the Straits of Gibraltar; and, in general, to all the ports of the Mediterranean, the Black Sea, and the Palus Mæotis or Sea of Azof. In all these parts they had founded settlements, whence they drew whatever was useful to themselves, or might prove so to others; and thus they enjoyed the three great branches of trade, as it is commonly divided into importation, exportation, and transportation. Such appears to have been their trade by sea; and as to that which they carried on by land in Syria, Mesopotamia, Assyria, Babylonia, Persia, Arabia, and even in India, it was not less extensive, and may give us an idea of what this people once was, and how deservedly their merchants are mentioned in Scripture as equal to princes. Their country was at that time the great warehouse, where every thing that could administer either to the necessities or luxury of mankind was to be found; and all this they distributed as they judged best for their own interest. The purple of Tyre, the glass of Sidon, and the fine linen made in this country, together with curious pieces of art in metals and wood, appear to have been the chief and almost only commodities of Phœnice itself. Indeed their territory was so small, that it is not to be imagined they could afford to export any products of their own growth.

Having thus spoken in general terms of the trade of the Phœnicians, we shall now touch upon their shipping, and some things remarkable in their navigation. Their larger vessels were of two sorts, being divided into round ships or gauli, and long ships, galleys, or triremes. When they drew up in line of battle, the gauli were disposed at a small distance from each other in the wings, or in the van and the rear; whilst their triremes were contracted together in the centre. If at any time they observed that a stranger kept them company in their voyage, or followed in their track, they were sure to get rid of him if they could, or deceive him if possible; and in this policy they went so far, as to venture the loss of their ships, and even their lives, so jealous were they of foreigners, and so tenaciously bent upon keeping the whole trade to themselves. To discourage other nations from engaging in commerce, they practised piracy, or at least pretended to be at war with such as they met when they thought themselves strongest. This was a natural stroke of policy on the part of a people who grasped at the whole commerce of the then known world. We must not forget to mention here the famous fishery of Tyre, which so remarkably enriched that city. The murex, or purple dye, has been celebrated by all the ancient writers.

PHŒNIX, the great palm or date-tree. There is only one species, viz. the *dactylifera*, or common date-tree, a native of Africa and the eastern countries, where it grows to fifty, sixty, and a hundred feet in height. The trunk is round, upright, and studded with protuberances, which are the vestiges of the decayed leaves. From the top issues forth a cluster of leaves or branches eight or nine feet long, extending all around like an umbrella, and bending a little towards the earth. The lower part produces a number of stalks like those of the middle, but these seldom shoot so high as four or five feet. The stalks, according to Adanson, diffuse the tree very considerably, so that, wherever it grows naturally in forests, it is extremely difficult to open a passage through its prickly leaves. The date-tree was introduced into Jamaica soon after the conquest of that island by the Spaniards. There are, however, but few of them in the island at the present time. The fruit is somewhat in the shape of an acorn. It is composed of a thin, light, and glossy membrane, somewhat pellucid and yellowish, which contains a fine, soft, and pulpy fruit, that is firm, sweet, and somewhat vinous to the taste, esculent, and wholesome; and within this is enclosed a solid, tough, and hard kernel, of a pale gray colour upon the outside, and finely marbled within like the nutmeg. For medicinal use dates are to be chosen large, full, fresh, yellow on the surface, soft and tender, not too much wrinkled; such as have a vinous taste, and do not rattle when shaken. They are produced in many parts of Europe, but never ripen perfectly there. The best are brought from Tunis; they are also very fine and good in Egypt, and in many parts of the East. Those of Spain and France look well; but they are never perfectly ripe, and very subject to decay. They are preserved three different ways; some pressed and dry; others pressed more moderately, and again moistened with their own juice; and others not pressed at all, but moistened with the juice of other dates, as they are packed up, which is done in baskets or skins. Those preserved in this last way are much the best. Dates have always been esteemed moderately strengthening and astringent.

Dates afford wholesome nourishment, and have a very agreeable taste when they are fresh; the Arabs, however, eat them without seasoning. They dry and harden them in the sun to reduce them to a kind of meal, which they lay up in store to supply themselves with food during the long journeys which they often undertake across their deserts. This simple food is sufficient to nourish them for a long time. The inhabitants of the Sahara also procure from their dates a kind of honey, which is exceedingly sweet. For this purpose they choose those which have the softest pulp; and having put them into a large jar with a hole in the bottom, they squeeze them by placing over them a weight of eight or ten pounds. The most fluid part of the substance, which drops through the hole, is what they call the honey of the date. Even the stones, though very hard, are not thrown away, but given to their camels and sheep as food, after they have been bruised or laid to soften in water.

Phœnix, in *Antiquity*, a famous bird, which is generally regarded by the moderns as fabulous. The ancients speak of this bird as single, or the only one of its kind. They describe it as of the size of an eagle, having its head finely crested with a beautiful plumage, its neck covered with feathers of a gold colour, and the rest of its body, except the tail, purple, and the eyes sparkling like stars. They hold that it lives five or six hundred years in the wilderness; that when thus advanced in age, it builds itself a pile of sweet wood and aromatic gums, which it fires with the wafting of its wings, and thus burns itself; and that from its ashes arises a worm, which in time grows up to be a phœnix. Hence the Phœnicians gave the name *phœnix* to the palm-tree, because, when burned down to the root, it rises again fairer than ever.

PHOLIS, an old name for gypsums or plaster-stones. It is derived from φολις, a *scale* or *small flake*, because these stones are composed of particles of that form.

PHONICS, the doctrine or science of sound, otherwise called acoustics. See ACOUSTICS.

PHORMINX, a stringed instrument used by the ancient Greeks, and probably by the Egyptians. Its nature is not known; but it is mentioned by Homer, Euripides, and others.

PHOSPHORUS, a name given to certain substances which shine in the dark without emitting heat. By this circumstance they are distinguished from the *pyrophori*, which, though they take fire on being exposed to the air, are yet entirely destitute of light before such exposure. Phosphori are divided into several kinds, known by the names of Bolognian phosphorus, Mr Canton's phosphorus, Baldwin's phosphorus, phosphorus of urine, and the like. The phosphorus of urine is by far the most remarkable, both with respect to the quantity of light which it emits, and its property of taking fire and burning very fiercely upon being slightly heated or rubbed.

PHOTINIANS, in *Ecclesiastical History*, were a sect of heretics in the fourth century who denied the divinity of our Lord. They derive their name from Photinus their founder, who was bishop of Sirmium, and a disciple of Marcellus. In the year 343 Photinus published his notions respecting the Deity, which were repugnant both to the orthodox and to the Arian systems. He asserted that Jesus Christ was born of the Holy Ghost and the Virgin Mary; that a certain divine emanation, which he called the Word, descended upon him; that, because of the union of the Divine Word with his human nature, he was called the Son of God, and even God himself; and that the Holy Ghost was not a person, but merely a celestial virtue proceeding from the Deity. Both parties condemned the bishop in the councils of Antioch and Milan, held in the years 345 and 347. He was also condemned by the council at Sirmium in 351, and having been degraded from the episcopal dignity, he died in exile in the year 372 or 375. His opinions were afterwards revived by Socinus.

PHOTINX, an ancient wind-instrument of Egypt, said to have been a kind of flute of a curved form. Several modern wind-instruments are curved.

PHOTIUS, patriarch of Constantinople, was one of the most remarkable men of his time, and by his merit raised himself to the patriarchate. When Bardas had driven Ignatius from the see, Photius was consecrated by Asbestus in 859. He condemned Ignatius in a synod, upon which the pope excommunicated him; and, to balance the account, Photius anathematized the pope. Basilius of Macedonia, whom Photius had reproved for the murder of the Emperor Michael, expelled him, and restored Ignatius; but afterwards, upon the death of Ignatius, Photius was re-established in the year 878. At last, being wrongfully accused of a conspiracy against the person of Leo the philosopher, son and successor of Basilius, he was expelled in 886, and is supposed to have died soon afterwards. He wrote a *Bibliotheca*, which contains an examination of two hundred and eighty authors; and we have also two hundred and fifty-three epistles of his, the *Nomocanon* under fourteen titles, and an abridgment of the acts of several councils. This great man was born in Constantinople, and descended from a very illustrious and noble family. His natural abilities were eminent, and he cultivated them with the greatest assiduity. There was no branch of literature, whether sacred or profane, and scarcely any art or science, in which he was not deeply versed. Indeed he appears to have been by far the greatest man of the age in which he lived; and he was so intimately concerned in the chief transactions of it, that ecclesiastical writers have on that account called it *Sæculum Photianum*. He was first raised to the chief dignities of the empire, being made principal secretary of state, captain of the guards, and a senator; and in all these stations he acquitted himself with a distinction suitable to his great abilities, having been an able statesman as well as a profound scholar. His rise to the patriarchate was very rapid; for when he was chosen to that office he was only a layman; but, that he might, as it were, be gradually raised to that dignity, he was made monk the first day, reader the next, and the following days sub-deacon, deacon, and priest, so that in the space of six days he attained to the highest office in the church. On the whole, however, his ardent love of glory and unbounded ambition led him to commit excesses which rendered him a scourge to those around him. Fabricius describes his *Bibliotheca*, or Library, as *non liber, sed insignis thesaurus*, not a book, but an illustrious treasure, in which are contained many curious things relating to authors, and many fragments of works which are nowhere else to be found. It was brought to light by Andreas Scottus, and communicated by him to David Hoeschelius, who caused it to be printed in 1601. Scottus, considering the great utility of this work, translated it into Latin, and printed his translation separately in the year 1606. The Greek text, together with the translation, was afterwards printed at Geneva in 1611.

PHOTOMETER, an instrument for ascertaining the intensity of light. See METEOROLOGY and OPTICS.

PHRASE, in *Grammar*, an elegant turn or manner of expression, peculiarly belonging to this or that occasion, this or that art, this or that language. Thus we say, an Italian *phrase*, an eastern *phrase*, a poetical *phrase*, a rhetorical *phrase*. Phrase is sometimes also used for a short sentence or small circuit of words constructed together. In this sense, Father Buffier divides phrases into complete and incomplete. Phrases are *complete* where there is a noun and a verb, each in its proper function; that is, where the noun expresses a subject, and the verb the thing affirmed of it. *Incomplete* phrases are those where the noun and the verb together only perform the office of a noun, and consist of several words, which, without affirming any thing, might be expressed by a single term. Thus, *that which is true*, is an incomplete phrase, and might be expressed in one word, *truth;* and again, *that which is true satisfies the mind*, might be converted into *truth satisfies the mind*.

PHRASEOLOGY, a collection of the phrases or the elegant expressions in any language.

PHREATIS, or PHREATTIUM, in Grecian antiquity, was a court belonging to the civil government of Athens, situated upon the sea-shore, in the Piræus. The name is commonly derived ἀπο του φρεατος, because it stood in a pit; or, as others suppose, it is formed from the name of the hero *Phreatus*. This court heard such causes as concerned persons who had fled from their own country for murder, or those who had fled for involuntary murder, and had afterwards committed a deliberate and wilful murder. The first who was tried in this place was Teucer, on a groundless suspicion that he had been accessory to the death of Ajax. The accused was not allowed to land, or so much as to cast anchor, but pleaded his cause in his bark, and if found guilty, he was committed to the mercy of the winds and waves, or, as some say, suffered there condign punishment; but if innocent, he was only cleared of the second fact, and, according to custom, underwent a twelvemonth's banishment for the former.

PHRENITIC, a term used to denote those who, without being absolutely mad, are subject to such strong sallies of imagination as in some measure pervert their judgment, and cause them to act in a way different from the more rational part of mankind.

PHRENOLOGY.

Definition.

PHRENOLOGY, derived from φρην, *the mind*, and λογος, *discourse*, is a term which has been recently applied to denote a new doctrine of mental philosophy, founded on a presumed knowledge of the functions of different portions of the brain, obtained by comparing their relative forms and magnitudes in different individuals, with the propensities and intellectual powers which these individuals are found respectively to possess. This term has of late years totally superseded the more unpretending titles of CRANIOLOGY and CRANIOSCOPY, by which this doctrine, in its earlier periods, and before it had aspired at effecting a revolution in psychology, was designated, and which simply implied the study of the external forms of the skull, both in men and animals, with a view to determine the size of the subjacent parts of the brain, and thence to derive indications as to the mental and moral qualities of each individual.

The original propounder of the doctrine which is the basis of phrenology was Dr. Gall, a physician of Vienna, whose system, matured in conjunction with Dr. Spurzheim, has attracted so much attention, and been so keenly discussed, both here and on the Continent, that we think it our duty to present our readers with a general outline of this pretended science.

Physiology of the brain imperfectly known.

Of the several parts which compose the human body, the mechanism of which has been so thoroughly unfolded by the diligence of modern anatomists, there are few whose use in the economy is wholly unknown. The intention and operation of every part of our frame subservient to the mechanical purposes of connexion, of locomotion, and of strength, such as the bones, muscles, and ligaments, are, in general, sufficiently apparent; the functions performed by the abdominal and thoracic viscera are, for the most part, well ascertained; and we are able, in like manner, to discern the adaptation of the organs of sense to receive appropriate impressions from surrounding objects. One organ alone, and an organ of vast importance in the system, connected with every other, and essentially interwoven with our sensitive existence, has baffled all investigation, and still presents a wide blank in this rich and cultivated field of knowledge. The brain, that large mass of pulpy substance, which fills the cavity of the cranium, is, even at the present day, as incomprehensible in its functions, as it is subtle and complex in its anatomy. It appears, indeed, to be sufficiently established, that the brain is, in some unknown way, subservient to sensation and voluntary motion, and is thereby the immediate agent by which the soul and body mutually exert an influence over each other: and it has also been very generally supposed, that this organ is immediately concerned in all our mental operations, besides being the instrument by which we feel and act. But the phenomena comprehended under the operations of the mind are exceedingly various and complicated, and are also of very different kinds; so that before we can reason concerning them, it is necessary that they should be properly distinguished and arranged. Metaphysicians have, accordingly, classed them as referable to our sentient, our intellectual, our active, and our moral powers. Further subdivision again is required; and the intellectual phenomena, for instance, are arranged according as they relate to the faculties of conception, association, memory, abstraction, judgment, imagination, invention, &c. Other phenomena are distributed under the heads of the different active principles, such as the propensities, the instincts, the affections, and the passions, which belong to our nature. Whilst we thus discover a great diversity in the functions of the mind, we observe also as great a complexity of structure in the organs by which they are performed. Shall we rest satisfied with an acquiescence in the general proposition, that the brain is the organ of thought? May we not rather regard it as a congeries of distinct organs, corresponding to the different faculties into which the mind may be analyzed; each organ having its appropriate office, and being immediately subservient to some particular function of the mind? The question has, indeed, presented itself to many physiologists; but few have ventured farther in attempting its solution, than to throw out some vague and general conjectures as to the uses of certain parts, or as to the supposed habitation of the sentient principle. Thus, for a long period it was held, that the cerebrum was the organ of perception, and the cerebellum the organ of memory. The cavities which are met with in the interior of the brain have often been considered as the scene of the intellectual operations. Nemesius, the first bishop of Emesa, under the reign of Theodosius, taught that the sensations had their seat in the anterior ventricles, memory in the middle, and understanding in the posterior ventricles. Albertus Magnus, in the thirteenth century, went so far as actually to delineate upon a head the supposed seat of the different faculties of the mind. He placed common sense in the forehead, or in the first ventricle of the brain, cogitation and judgment in the second, memory and moving power in the third. Peter de Montagnana, in 1491, published the figure of a head, on which were indicated the seat of the *sensus communis*, the *cellula imaginativa*, *cellula æstimativa seu cogitativa*, *cellula memorativa*, and *cellula rationalis*. Ludovico Dolci, Servito, and a great number of other writers, have hazarded similar hypotheses as to the locality of the different faculties. Both Haller and Van Swieten fancied that the internal senses occupy different places in the brain; but they considered its whole organization as too complicated, too intricate, and too difficult, to allow of any hope that the seat of memory, of judgment, or of imagination, could ever be detected.

Histor Dr. Ga speculations.

In the pursuit of this speculation, no one has engaged with more ardour and perseverance than Dr. Gall, who, after many years of patient labour, and much fruitless wandering in search of the truth, conceived that he had at last discovered the clue which was to conduct us through the mazes of this labyrinth, and enable us to arrive at a more accurate knowledge of human nature, and of the means which may conduce to its perfection. The account which he gave of the circumstances that gradually drew his attention to the subject, and of his progress in this new path of discovery, is as follows: Brought up in the midst of a numerous family, and naturally gifted with the talent for observation, he was struck, even when a boy, with the diversities of disposition and of character amongst his brothers and sisters, and the companions with whom he was educated. He remarked, that each excelled in a particular study, or was distinguished by a peculiar turn of mind. One was noted for the beauty of his handwriting; another for his quickness at arithmetic; a third for his aptitude in learning languages; a fourth for remembering everything that he read in history. This diversity was apparent in all that they did; thus the style of composition of the one was remarkable for its flowing and elegant periods; of another for its baldness and dryness; of a third for its condensation and vigour. Many displayed talents for arts which had never been taught them; they excelled, perhaps, in drawing, or in the execution of works of mechanism; some sought for amusement in noisy sports, others preferred cultivating their gardens; a few placed their chief delight in rambling through fields and forests, and in collecting birds, insects, and flowers. One was of a social and affectionate disposition, another was selfish and reserved; a third was fickle, and not to be depended upon. The great facility with which some of his school-fellows could commit their tasks to memory, which to him was a work of immense labour, although in matters of reasoning and judgment he felt himself their superior, often proved a grievous source of mortification, and excited in him a strong desire to know the cause of this difference. He at length remarked, that all the boys gifted with this kind of memory had large and prominent eyes. He afterwards went to the university; and directing his attention to all those among his fellow-students, who presented the same peculiarity of feature, he learned that they were all distinguished by the tenacity of their memories; as, indeed, he soon found to his cost, for they were sure to leave him far behind in every competition, where the exercise of this faculty was essential to success. This observation gave rise to others; it suggested the notion, that other intellectual endowments might also be indicated by the features; and Gall, by degrees, came to imagine that he had discovered a number of external signs, which respectively indicated a decided turn for painting, for music, for mechanical arts, or other objects. He had by this time commenced the study of medicine; and, in the course of his academical instructions, he heard much about the functions of the muscles and viscera; but nothing was taught about those of the brain and its different parts. It then occurred to him, that the differences he had already noticed in the external configuration of the head, as connected with certain dispositions of mind, were occasioned by differences in the form of the brain. Delighted with the prospect which this idea opened to him of discovering the functions of particular parts of this organ, and of obtaining an insight into the connexion between the mind and the body, he formed the resolution of prosecuting the research, till he had either accomplished his object, or satisfied himself that it was not to be attained by that method. Natural history, which had long been his favourite study, furnished ample scope for the extension of these inquiries. He had been in the practice of collecting plants and animals of various kinds, and of arranging them, not according to the artificial methods of classification detailed in books of science, but according to their more obvious resemblances. He now studied the relations between their external forms, and their natural habits and dispositions. Dogs showed him the greatest diversities in their capabilities of being educated. He remarked that some were naturally expert at the chace, while others, of the same breed, could not be trained without the utmost difficulty; that some perpetually lost themselves, while others found their way home from great distances. In birds, he observed that one would listen with attention to a tune which it heard, and immediately learn it; while another of the very same brood would sing nothing but the note that was natural to it. Whence, he would ask himself, can arise this wide diversity among individuals?

The solution of this difficult question was not to be hoped for, unless by means of observations conducted on the largest possible scale. He therefore set about examining all the skulls he could lay hold of, that had belonged to individuals whose history was known. He looked out for all persons in any way distinguished for a particular talent or moral quality. He examined their heads with great attention, and noted the peculiarities in their shape. He also collected observations on other individuals, who were remarkable for the weakness of any faculty, and then compared together the positive and negative indications. On the other hand, when he chanced to meet with a head that presented some singularity in shape, he was at much pains to obtain information as to the moral and intellectual character of the person to whom it belonged. When he had no other resource, he did not scruple, as Dr. Spurzheim informs us, to address his questions directly to the person in whose head he observed any distinct protuberance. We are also told, that he was in the habit of collecting around him the boys he met with in the streets of Vienna, and of inducing them, by petty bribes, to confess their own faults, and betray those of their companions. He excited them, for instance, to fight together, in order to discover which possessed most courage, and thence drew inferences as to the organ which prompted that sentiment. In order to obtain more precise data for his conclusions, he endeavoured to procure models of the more remarkable heads that he met with, and generally got permission from the individuals themselves to take a cast of their heads in plaster of Paris. The Count of Sauran, then minister of police at Vienna, gave him material assistance in effecting these objects; and he was thus in no long time in possession of a very large collection of casts, all bearing more or less upon the several points of his theory. If he happened to hear of the death of any one whose head he had already moulded, he was at great pains to procure his skull, that he might compare the form of its different parts with the shape of the head during life. As it was soon known that the doctor aimed chiefly at those who possessed some remarkable talent, a very general alarm spread itself amongst the inhabitants of Vienna; and not a few were pursued with the terror of being selected as the subjects of cranioscopical investigation, and of their skulls being destined to make a figure in his anatomical cabinet. The aged Mr. Denis, librarian to the emperor, is said to have inserted an express clause in his will, to protect his head from the keen scalpel of Dr. Gall. Notwithstanding these fears and precautions, he contrived to amass an extensive collection of skulls, as well as of heads, in illustration of his doctrines. He next availed himself of the aid of comparative anatomy; and having no family to provide for, spared no expense in procuring skulls of all sorts of animals, with a view of tracing the form and size of corresponding organs throughout the whole series. Being physician to the establishment for the *deaf and dumb* at Vienna, he had opportunities of observing the natural features of uncultivated minds, and the various degrees in which they were susceptible of education. With the same view, he used to call together into his house persons of the lowest class, such as coachmen, and beggars in the street, and excite them to display their characters before him. His professional practice made him acquainted with a great number of families, and afforded him many opportunities of making valuable observations. He neglected no means of instruction that could be derived from the inspection of the heads of patients labouring under different forms of insanity. He was physician to the director of establishments for education, and was allowed to examine every child who excelled, or showed any remarkable disposition. He visited the prisons and houses of correction, as well as the hospitals for idiots and lunatics. He took casts of the heads of criminals, inquired into the offences for which they were confined, and collected the history of their lives; and thus derived from every quarter materials for bringing his theory to perfection.

His Lectures.

As his observations multiplied, he became sensible that he had fallen into many errors in the earlier periods of his inquiries, and was forced to give up many of his favourite opinions, which he found had been too hastily adopted, with regard to the general form of the head, as connected with the character of the individual. He felt the necessity of being in future more on his guard, and resolved to institute a separate examination of the different regions of the skull; and although he was here, also, frequently obliged to shift his ground in assigning the function of each part, his researches were, on the whole, attended with more uniform success. By degrees he acquired greater confidence in the stability of his conclusions, and at length ventured to announce them to the public, by the delivery of lectures on his new science. His doctrines were eagerly received, and much canvassed at Vienna; but their fame had no sooner reached the Austrian court, than a violent outcry was raised against them by the bigoted priests, who controlled all the operations of that weak and misguided government, and who represented these doctrines as tending to materialism and atheism. The consequence of this senseless clamour was, that Gall was interdicted from lecturing. But the number of those to whom he had communicated the principles of his art, and in whom he had infused a strong desire to continue to profit by his instructions, was by this time very considerable, especially among the strangers who happened to be at Vienna. They formed a strong party in his favour, and made such interest at court, principally through the medium of the foreign ambassadors, that the doctor was again permitted to resume his prelections, on condition that he delivered them to foreigners only; as it was wisely considered that their being exposed to the dangers of knowledge, would not be of any material consequence to the state, as long as care was taken that the infection did not spread farther; the emperor kindly preserving the bliss of ignorance for the exclusive enjoyment of his Austrian subjects.

Publications and travels.

It was long before Gall committed himself by writing on the subject that had procured him so much celebrity. He merely announced, in 1798, in a letter addressed to Baron Retzer, which appeared in the *Deutsche Merkur* of Wieland, his design of publishing a large work on the new theory, of which he affords his readers only an imperfect glimpse. A detailed account was afterwards given by M. Froreiss, one of his pupils, in the second volume of Voight's *Magazin Physique;* and an amusing outline appeared from the pen of M. Charles Villers, in a letter addressed to Cuvier. Various surreptitious copies of his lectures were also circulated throughout the protestant states of Germany, where they excited so much curiosity, that Dr. Gall was at length induced to make a tour for the purpose of delivering them himself at the principal universities in the north of Germany. With this view he visited Dresden, Berlin, Hallé, Jena, Weimar, Göttingen, Hamburgh, &c. and every where met with the most flattering reception, being invited to the several courts of the states through which he passed, and treated with the honours due to a distinguished literary character. By frequenting the first societies, and conversing with the best informed persons, he had ample opportunities of extending his observations, and he was attentive to improve these opportunities to the utmost of his power. Dr. Spurzheim, who had at an early period been associated with him in these inquiries, and who had devoted himself particularly to the anatomical researches they comprised, accompanied him in this tour, and participated in all his labours. Dr. Gall at length settled in Paris, where he continued his pursuits and lectures, and united with them the practice of his profession.

Other works on his system.

In 1810 Drs. Gall and Spurzheim published, in conjunction, the first volume, in quarto, of the work they had announced, and which was to contain a full account of their doctrines, under the title of *Anatomie et Physiologie du système nerveux en général, et du cerveau en particulier, avec des observations sur la possibilité de reconnoitre plusieurs dispositions intellectuelles et morales de l'homme et des animaux, par la configuration de leurs têtes.* The first part of the second volume appeared in 1812. This work, together with the one published in 1815, by Dr. Spurzheim, entitled *The Physiognomical System of Drs. Gall and Spurzheim, founded on an anatomical and physiological examination of the nervous system in general, and of the brain in particular, and indicating the dispositions and manifestations of the mind,* contain the most authentic account of their system. Information on the subject may, however, be derived from the following books, besides those of Froreiss and Villers, already mentioned. The best of the foreign works is that of Professor Bischoff, entitled *Darstellung der Gall' schen Gehirnund Schädellehre, nebst Bemerkungen über diese Lehre,* von D. W. Hufeland, Berlin, 1805. At Dresden, in 1806, Bloede published a similar work, viz. *Galls Lehre über die Verrichtungen des Gehirns, nach dessen zu Dresden gehaltenen Vorlesungen;* and at Paris, in the same year, we have, from the pen of Démangeon, *Physiologie intellectuelle, ou dévelopement de la doctrine du Professeur Gall.* A small tract in English, entitled *Some Account of Dr. Gall's new Theory of Physiognomy, founded upon the Anatomy and Physiology of the Brain, and the Form of the Skull,* appeared in London in 1807, and is chiefly taken from Dr. Bischoff's work, including the critical strictures of Dr. Hufeland. Soon after the publication of Dr. Spurzheim's book, a small volume, principally reprinted from a short tract in the *Pamphleteer,* was given to the public by Mr. Thomas Forster, under the title of *Sketch of the New Anatomy and Physiology of the Brain and Nervous System of Drs. Gall and Spurzheim, considered as comprehending a complete system of Zoonomy, with observations on its tendency to the improvement of education, of punishment, and of the treatment of insanity.* Two pamphlets in opposition to these doctrines were published by Professor Walter of Berlin, in 1805, of which, as well as of Bischoff's work, a short account is given in the *Edinburgh Medical and Surgical Journal* for July 1806. Dr. Spurzheim having conceived that he was unfairly attacked in some of the Reviews, thought proper to publish a reply, in a pamphlet which made its appearance at Edinburgh in 1817, entitled *Examination of the Objections made in Britain against the Doctrines of Gall and Spurzheim.* These, together with the lectures delivered in London by Dr. Spurzheim, are the sources which have supplied the materials for the following summary.

The hum faculties innate.

It is laid down both by Gall and Spurzheim as the foundation of their doctrines, that the nature of man, like that of all other created beings, is determinate, and that the faculties with which he is endowed are *innate;* that is, that they are implanted in him at his first formation, and are not the result merely of the external circumstances in which he may afterwards happen to be placed, nor of the wants and necessities to which these circumstances may have given rise. They warn us that this opinion is by no means at variance with that of Locke, who argues only against the innateness of ideas, and not of the faculties or capacities of receiving ideas. Education, doubtless, has a powerful influence in modifying and giving certain directions to these faculties; but the faculties themselves, that is, the capacities of feeling, of intellect, and of action, must have already pre-existed before they could be called into play, and thus produce the various phenomena which diversify the scene of human life. Savages have at different times been found in woods destitute of all the ordinary faculties of rational beings. Their resemblance to brutes has been supposed to be the consequence of their total want of education; but, when we come to examine into their real condition, we shall find that they are wretched beings, with great bodily defects; for the most part deeply tainted with scrofula, and almost always complete idiots. In general, they appear to have been abandoned in their childhood by their parents, to whom they were burdensome. The pretended savage of Aveyron, who was kept in the Institution for the Deaf and Dumb at Paris, was almost completely idiotical. He was quite deaf, and his head and body were incessantly in motion from side to side, even when he was sitting.

ginally erent in indi- al.

In estimating the causes of that diversity which we see prevailing in the characters and faculties of individuals, much has been ascribed to the influence of diet, mode of living, and the impressions received in early infancy, while the organs are yet tender, and highly susceptible of every kind of external influence. But the operation of these causes, as well as the power of education in general, is much too limited to explain the immense differences we observe among different men, and even among different children of the same family. Helvetius and other bold metaphysicians have maintained the paradox, that all men are born originally the same, and are moulded into what they afterwards become solely by the force of external circumstances. Genius, according to this doctrine, is a mere creature of the fancy, and originally belongs no more to one man than to another. Train all men alike, and their powers, their attainments, and their actions, will all be similar. Accident, more than design or premeditation, has fixed the destinies of great men, as well as disposed of those who are unknown to fame. "Demosthenes," say these philosophers, "became eloquent, because he heard an oration of Callistratus, whose eloquence made so deep an impression on his mind, that he aspired only to acquire this talent. Vaucanson excelled in mathematics, because, being obliged, when a child, to stay alone in the waiting room of his mother's confessor, he found there a clock, examined its wheels, and endeavoured, with the help of a bad knife, to make a similar machine of wood. He succeeded; and one step leading on to another, he arrived at the construction of his wonderful automatons. Milton would not have composed his *Paradise Lost*, had he not been deprived of his place of secretary to Cromwell. Shakspeare composed his tragedies because he was an actor, and he became an actor because he was forced to leave his native place on account of some juvenile errors. Corneille fell in love, made verses for the object of his passion, and thence became a great poet. An apple fell from a tree at the feet of Newton, while he was in a contemplative mood: this event, so trivial in itself, led him to the theory of gravitation." Reflections of a similar kind are often met with in the writings of poets and moralists. Those contained in Gray's *Elegy* must be familiar to all our readers. Dr. Johnson considered talents or genius as a thing that, when once existing, might be directed any way. Newton, he thought, might have become a Shakspeare, for, said he, a man who can run fifty miles to the south, can run fifty miles to the north.

Yet these are but the ingenious speculations of the theorist, more calculated to dazzle than to convince, and obviously in contradiction with the daily experience of mankind. Original differences in the constitution of the mind exist as certainly as in that of the body; and doubtless are dependent upon differences in organization. Children often show, from their earliest infancy, the germs of those peculiarities of character which adhere to them through life, which hardly any education can alter, and which no condition of life or variation of circumstances can afterwards affect. It is needless to expatiate on the subject of the diversities of intellectual powers exhibited by different individuals under the very same circumstances of birth and education; diversities which, as we have already seen, first directed the mind of Dr. Gall to his physiognomical researches. Many of these peculiarities are unquestionably derived from the parent, and are observed to prevail in certain families, and to descend through several successive generations.

e mental lties exer- d.

That no sensation, or other affection of the mind, and that no operation of intellect can take place without a certain condition of the nervous system, is a position established by so many direct proofs, that its truth must be generally admitted. The question becomes more difficult when we come to inquire what part of the system it is that exercises these functions. It is quite clear that the sentient principle does not reside in the nerves, or in the part which receives the first impression from the external cause of sensation. The opinion which has been embraced by many physiologists, and particularly Bichât, that while the brain is the organ of the intellectual faculties, the nerves of the great viscera of the abdomen and thorax are the seat of the moral sentiments, is at variance with a multitude of facts in comparative anatomy. There are animals endowed with the faculties ascribed to these nervous plexuses, or ganglions of the great sympathetic nerves, distributed to certain viscera, which have not the viscera in question. On the other hand, most quadrupeds have viscera analogous in their whole structure to those in man, without having the faculties of which in man it is pretended they are the seat. We have a complete series of proofs that the nerves, of themselves, and without an uninterrupted continuity with the brain, can produce neither sensation nor voluntary motion. Compression of the brain, by any cause, produces an entire suspension of all sensation and consciousness, and puts a complete stop to every operation of intellect. All the other parts of the body, on the other hand, may be wounded or destroyed, and even the nervous mass of the spinal marrow may be compressed or injured, at a certain distance from the brain, without the immediate destruction of the feelings and intellectual faculties. In tetanus, produced by a cause remote from the brain, the other nervous systems are affected in the most violent manner, while the functions of the mind continue unimpaired.

Proved by the developement of the brain;

In children, Dr. Spurzheim observes, the brain is yet pulpy, and the faculties imperfect; its growth accompanies their improvement; its maturity marks their greatest degree of vigour. If its developement has been considerable, the manifestations of these powers are energetic; if small, they are comparatively weak. In proportion as the organization of the brain decreases, the strength of the moral sentiments and intellectual faculties decreases also. If the developement of the brain take place too early or too late, the faculties exhibit corresponding variations. Certain faculties are more active in men, and others in women, according to the difference of their cerebral organization; and peculiarities of character are hereditary, according as the corresponding organization of the brain, on which they depend, is propagated from parents to their children.

by injuries and diseases;

Although many facts show that considerable injuries may be sustained by the brain without detriment to the mental faculties, yet as a general principle, it is contended by Dr. Spurzheim, that these faculties are weakened or destroyed in proportion as the brain is mechanically altered. It is, however, certain, that physiologists are by no means agreed as to this point; and that innumerable cases might be quoted in direct contradiction to this principle. These are attempted to be explained away by the general supposition, that most of them are the result of very inaccurate observations, in which the statement of the facts has been distorted and vitiated by ignorance, prejudice, or credulity; and that the rest are inconclusive as to the general question, from the observers not being aware of the real functions of the injured parts, and being inattentive to the circumstance, that almost all the parts of the brain being double, the loss of those on one side would scarcely be felt, as long as the corresponding organs on the other side remained entire. On the other hand, it should be recollected, that a derangement in an organ may occur of such a nature as that our senses cannot enable us to discover it. How often is this exemplified in fatal diseases of the nervous system, such as hydrophobia, tetanus, and atonic gout. Analogy shows us other parts where apparently no proportion is preserved between the injury and the derangement of function. Sometimes large abscesses are met with in the lungs without much disturbance of the function of respiration; and ossification of the heart, without any sensible affection of the circulation. In persons possessed of great irritability, very slight wounds of the brain may produce serious effects, while considerable wounds in others, who are less irritable, shall be attended with no bad consequences. This consideration will go a great way towards explaining the fact, that in many cases of insanity, instead of our discovering any change in the brain, a diseased state has been observed in the liver, the bowels, and other viscera; and may serve as an answer to the assertions and objections of Pinel, who states that the most accurate dissections have not taught us any thing with regard to the seat of mental alienation, and that we have no sufficient data to conclude, from diseases of the brain, that it is exclusively the organ of the intellectual faculties.

by dissections in hydrocephalus;

Those who have opposed the theory of the subserviency of the brain to the operations of mind, have laid great stress upon an argument derived from the phenomena of hydrocephalus. In patients afflicted with this disease, the brain appears to be destroyed and replaced by water; and yet the intellectual and moral faculties have remained perfect to the last. Drs. Gall and Spurzheim conceive, that the facts have been very erroneously represented; and that the only alteration which the brain sustains in these cases, is a displacement of its parts, and not an absorption of its substance. The effused fluid, by accumulating in the ventricles, gradually unfolds the convolutions of the hemispheres of the brain, and expands them to such a degree, that they are reduced to a thin stratum of substance, constituting a sort of bag, within which the fluid is still contained. This stratum of brain is sometimes not more than a line in thickness, and is generally lacerated in attempting the dissection; in which case the water rushes out, the real structure escapes notice, and the fluid is erroneously supposed to have been accumulated between the brain and its membranes.

by monsters, and by direct experiment.

It has been advanced, as another objection to the same theory, that monsters are sometimes born without any brain, who yet suck and perform various movements. Actions of this kind, however, are purely automatic, and appear to be unattended with consciousness; with such actions the brain has no concern whatever. Some have founded their opposition to the theory, on the result of some experiments of Duverney on pigeons, which, it is alleged, continued to perform all their animal functions after the whole of the brain had been removed from the skull. But Dr. Spurzheim, on repeating these experiments on birds and rabbits, found, indeed, that the destruction of the superior parts of the brain does not destroy the functions of the five senses and of voluntary motion, but that it is impossible to take out all the cerebral mass without killing the animal. As soon as the *corpora striata* and optic *thalami* are wounded, convulsions and death ensue; consequently he does not hesitate to pronounce the account given by Duverney to be entirely false. He, in like manner, wholly discredits the stories related by Morgagni, Zacutus, Lusitanus, Bartholine, Haller, Vallisneri, Moreschi, Giro, Dr. Simson, Soëmmerring, and others, concerning petrified or ossified brains being found in individuals, without prejudice to the exercise of their intellectual faculties. He admits it to be doubtful, how far, in perfect animals, the brain may be necessary to the passive consciousness of the external senses; but deems it certain, that the exertions of the will, including voluntary motion and reflection, depend entirely upon the brain; no phenomenon of this kind ever taking place without that organ.

Hypothesis of the plurality of organs.

Concluding, therefore, that the brain is the organ of the sensitive, the intellectual, and the moral faculties, we have next to inquire, whether these faculties are exercised in common by the whole, or any particular portion of the brain, or whether, on the other hand, they are more especially the offices of different parts of that organ. Dr. Gall adopts the latter of these opinions, and upon this view of the subject is the whole of his system founded. The following is the reasoning on which he builds it.

Arguments in its favour derived from there being no assignable censorium commune;

Physiologists, influenced by the metaphysical tenets of the schools, have often maintained, that the soul, being simple, its material residence must be simple also, and that all the nerves must end in one point; or, which amounts to the same, that they can have but one common origin, because each individual has but one soul. Bonnet, Haller, and others, who had extended its seat to the whole substance of the brain, were opposed by these metaphysicians, who did not reflect that a little more or less room could not enable them to explain any better the nature of the soul; nor that, as Van Swieten and Tiedemann remark, a material point, in which all ideas and sensations should centre, is inconceivable, in consequence of the confusion and disorder that would result from such an arrangement. It appears ridiculous, indeed, that the physiologist, to whom all nature is open, should direct his researches and inductions by the guidance of such frivolous speculations. Great pains were, however, taken to determine this central point, or *sensorium commune;* but it is enough to enumerate the various and contradictory opinions that have been held with regard to it, in order to be satisfied of the utter futility of this research. Descartes, in his treatise on the *Passions*, labours to prove that the soul is concentrated in the pineal gland. This hypothesis continued in fashion for some time, till it found an enemy in a follower of Descartes, the Dutch physician Boutekoe, who dislodged the soul from its narrow watch-tower in the pineal gland, and confined it in the more spacious prison of the *corpus callosum.* Lancisi, Maria, and La Peyronie, successively declared themselves in favour of this new opinion; and the latter of these anatomists wrote a memoir in support of it, which was printed by the Academy of Sciences in 1741, and which has since been republished separately. Digby next transferred the soul to the *septum lucidum* in place of the *corpus callosum.* Vieussens allowed it greater latitude, assigning for its boundaries those of the *centrum ovale* of the medullary substance. Willis, again, restricted it to the *corpora striata;* Serveto, to the aqueduct of Sylvius. Wharton and Schellhammer placed it in the commencement of the spinal marrow; Molinetti and Wrisberg in the *pons Varolii;* Crusius and Meig in the origin of the *medulla oblongata;* whilst Drelincourt and others lodged it altogether in the cerebellum. Lastly, Soëmmerring imagined the soul to reside in the serosity which moistens the inner surface of the ventricles, to which he had traced the extremities of many nerves from the organs of sense; and conceives that the different motions or oscillations of this fluid are the immediate material cause of our sensations.

from various analogies;

Discarding the notion that the functions of sense and intellect are concentrated in any particular point or portion of the brain, let us next examine the opinion that all the faculties are exercised by the whole mass of brain considered as one organ. We may, in the first place, remark, that the analogy of other parts of the system is adverse to this hypothesis. Every different secretion has its appropriate gland, the offices of which are never interchanged. The liver never secrets urine, nor the kidneys bile. The five external senses are distinct and independent of one another. Every where do we observe that nature, in order to produce various effects, has varied the material organs. The structure of the brain in its different parts, is far from being simple and uniform; it is composed of two substances; the one soft, pulpy, and ash-coloured; the other white, opaque, and fibrous in its texture. The fibres of the latter run parallel to each other, having, at the same time, various collateral connexions, but by no means uniting in any one central part which can be considered as their common origin or termination. The parts of the brain are numerous, and distinct from one another, bearing evidence of a very complex and artificial construction. They are constant in their general arrangement in different subjects, shewing in this respect a striking contrast with the distribution of blood-vessels, or even the disposition of the muscles and viscera, in which it is so common to meet with variations. Comparative, as well as human anatomy, furnishes strong analogical arguments in favour of a plurality of the cerebral organs, corresponding to the plurality of faculties. However defective may be our knowledge of the structure of these organs in the lower animals, still a general comparison of their faculties, as we ascend in the scale of being, shows us that the number of these faculties increases in proportion as the cerebral parts are multiplied. The immense augmentation of the powers of intellect which we behold in man, when compared with the limited instincts of animals, is neither in proportion to the increased size of the five external senses, nor of any other part of the body, but to the increase of the cerebral organs only. It is the great size of the hemispheres of the brain, more especially, that characterizes this organ in man, and establishes its superiority, as an instrument of intellect, over that of all other animals. Man unites in himself all the organs which are variously scattered and distributed among the brute creation; but he has also organs in his brain, which no other animal besides himself possesses; and these are the seats of faculties of a higher order, peculiar to him alone.

f n the d rsity of c acters a ngst n.

Considerations arising from the differences in the proportional energy with which the faculties manifest themselves in different individuals, are also in favour of the plurality and independence of the organs. If the brain were one simple organ of mind, and alike instrumental in all its faculties and operations, wherever we met with any one faculty in a state of high energy, we must suppose the whole organ adapted to produce this degree of energy, and ought to expect its other operations to be equally energetic. Yet we may find the same individual remarkably deficient in other faculties, which are equally dependent on this organ. One person shall excel in verbal memory, while he cannot combine two ideas philosophically; another is a great painter, but a bad musician, or a wretched poet; another is a good poet, but a bad general. If the brain be a single instrument, it cannot be at once both weak and strong; it cannot exhibit one faculty in its perfection, and another in a very limited extent. But all difficulty vanishes if we admit it to be an assemblage of many organs; for the combinations of these organs may be as infinitely diversified as the actions and powers of man. The argument derives additional force from the readiness with which this theory may be applied to explain the diversity of character we meet with in the brute creation, and especially to the varieties of disposition observable among some of our domestic animals, which, under the same circumstances of education, exhibit such different qualities. In like manner, the diversity of character in the same individual, at different periods of his life, are most readily explicable on the supposition of distinct organs, which have their respective periods of growth, maturity, and decline. The analogy of the external senses is also strongly in favour of the same doctrine. Thus the taste and smell appear earlier than the senses of seeing and hearing, because their respective organs are earlier developed. This reasoning will be confirmed when it is found, as will afterwards be shown, that the proportional size of the different parts of the brain is very different in different individuals. Is it not, therefore, reasonable to suppose, that the different energies of the several functions of the mind are connected with these differences in the structure of the organs which respectively produce them?

fro na- logy

The faculties of animal life are incapable of long continued exertion; rest is necessary for the renovation of their powers. Fatigue is the consequence of the prolonged action of the muscles of voluntary motion; but when one set of muscles are fatigued, the power of others is still unimpaired, and they are ready to be employed in a different action, without any additional fatigue. When we have been long sitting, we are relieved by standing; and even the bed-ridden find ease from a change of posture. Our eyes, in like manner, may be fatigued by looking at pictures; but we can then listen to music, because there is one organ for seeing, and another for hearing. It is well known that study, long protracted, produces fatigue; but we can continue to study, provided we change the object of attention. If the brain were a single organ, the whole of which is employed in performing all the functions of mind, a new form of study should increase instead of relieving the sense of fatigue. Thus the analogy is complete between the phenomena of mental and bodily exertion. Are we not, then, justified in extending it to the instruments by which these operations of mind and body are effected?

from the phenomena of sleep, dreaming, and somnambulism:

The phenomena of sleep are also readily accounted for on this hypothesis. During this state all the organs do not remain inactive; but sometimes a particular organ enters into action, and this constitutes dreaming. The state of vigilance is that in which the will can put in action the organs of intellectual faculties, of the five senses, and of voluntary motion; but it is incorrect to define it as the state in which all these organs are active, for it is impossible that all the faculties should be active at the same moment. Somnambulism may be regarded as a state of still more incomplete sleep, or one in which several organs are watching. If, during sleep, the action of the brain is partial and is propagated to the muscles, locomotion takes place; if to the vocal organs, the sleeping person speaks. All this may take place in different degrees. Some persons dream and speak in their sleep; others dream, speak, hear, and answer; others, besides dreaming, rise, walk, and do various things. This latter state is called somnambulism; that is, the state of walking during sleep. Now as the ear can hear, so the eyes may see, while the other organs sleep; and there are undoubted facts which prove that several persons in the state of somnambulism have seen; but it has always been with the eyes open. There are also convulsive fits in which the patients see without hearing, or *vice versa*. Some somnambulists do things of which they are not capable in a state of watching; and dreaming persons reason sometimes better than they do when awake. This phenomenon is not astonishing. If we wish to reflect upon any subject, we avoid noise, and all external impressions; we cover the eyes with our hands, and we put to rest a great number of organs, in order to concentrate all vital power in one, or in a few. In the state of dreaming and somnambulism this naturally happens; consequently the manifestations of the active organs are then more perfect and more energetic; the sensations are more lively, and the reflections deeper than in a state of watching.

from states of disease;

States of disease are also adduced as proving the plurality of the cerebral organs. In many cases of insanity we find only one faculty deranged, whilst all the rest are in a perfectly sound state. Lunatics, on the other hand, are met with, who are reasonable only while pursuing some particular train of thought. There was a chemist, for instance, who was insane on every subject except chemistry. An embroiderer, during her paroxyms of insanity, while uttering the greatest absurdities, calculated correctly how much stuff was necessary to such or such a piece of work. The effects of blows, or other injuries on the head, supply facts of a similar kind, which afford still more convincing proofs that the brain is susceptible of being very partially affected. Some persons lose from this cause the memory of proper names, while they preserve the memory of words which indicate the qualities of objects. One Lereard of Marseilles, after having received a blow from a foil in the orbit, lost entirely the memory of names; sometimes he did not recollect those of his intimate friends, or even of his father. Cuvier, in his historical eulogium on Broussonet, states that this celebrated botanist, after having recoverd from an apoplectic fit, never could recollect proper names nor substantives, though he had recovered his prodigious memory with respect to other objects. He knew plants, their figure, leaves, and colours; he recollected the adjectives, but could never recover the generic substantives by which they were designated. These and similar instances of partial affections of the faculties support the supposition of their being owing to different conditions of various parts of the brain subservient to these faculties.

and from authorities.

Lastly, the doctrine that different portions of the brain exercise different mental functions, is countenanced by numerous authorities in former as well as in modern times. It is expressly stated in the writings of Boerhaave, Van Swieten, Haller, Prochaska, Soëmmerring, &c.; and the Academy of Dijon long ago proposed it as a prize-question, to determine the situation of these different cerebral organs. Charles Bonnet, indeed, went the length of maintaining that each fibre of the brain is a particular organ of the soul.

Charge of materialism unfounded.

It seems hardly necessary to expose the absurdity of the accusation that these doctrines tend particularly to materialism, although the dread of such a consequence has been sanctioned by royal edicts. There are two opinions only, which, in respect to this question, stand opposed to each other; namely, that which asserts perception to take place by the intervention of a material organ, and that which asserts it to take place immediately by the energies of the mind itself, or at least without the intervention of the body. The doctrines of Gall are unquestionably incompatible with this last opinion, that is, with pure immaterialism, which may in fact be regarded as denying the existence of matter altogether. This sceptical spiritualism can be avoided only by the admission of the necessity of a material organ; and if this be admitted, any modification of such opinion, that does not exclude mind as the ultimate percipient, must be equally remote from absolute materialism. The immaterialist believes that it is the soul which sees and the soul which hears, as much as that it is the soul which judges and the soul which imagines; and since he does not condemn, as impious, the allotment of different organs of sight and hearing, what greater heresy is there in the allotment of different parts of the sensorium, as the organs of judgment and imagination? If, indeed, any one were to say, that the affections of these parts are themselves judgment and imagination, he would be a materialist; but he would be as much a materialist, if he should say, that the affections of the organs of sight and hearing are themselves the ideas of colour and sound.

Determination of the functions of the cerebral organs, by their relative size.

Supposing it, then, established that each function of the mind is exercised by a separate portion of the brain, let us next inquire whether observation can furnish us with any means of determining the precise nature of the function, to which each particular organ is subservient. Although it is clear that the adaptation of each organ to the performance of its office, must be wholly dependent on its particular organization, yet it is equally evident that no consideration of its general structure as shewn to us by anatomy, can teach us *a priori* what such function really is, and still less what may be its degree of energy, or its peculiar quality and modifications. The energy of the function must in all cases depend on certain conditions of the organ, such as the perfection of its original constitution, its elaborate texture, its relative size, and the degree of exercise it has received; and will also be regulated by the influence which other faculties may exert on its operations. The only one among these conditions, which is open to observation, is the relative size of the organ. In general, we find that the properties of bodies act with an energy proportionate to their size. A large loadstone attracts a greater mass of iron than a small loadstone. A large muscle, in like manner, is stronger than a small one. If the nerves of the external senses be larger on one side of the body, the functions on that side are also stronger. Comparative physiology shews us that the olfactory, optic, and auditory nerves of those animals which are distinguished for the excellence of their smell, sight, or hearing, are marked by being numerous and large, evincing a more elaborate developement. The coincidence is so uniform as to justify the general inference, that wherever any organ is met with in a higher state of developement, we may there expect to find the power dependent on it increased in energy in the same proportion. May not this analogy be fairly extended to the organs which compose the brain? Our present object, it must be recollected, is not to determine every degree of activity existing in a cerebral part, but merely the *nature* of its function; and for this purpose the indication afforded by its comparative size, in different cases, will suffice.

Process fo conducting the inquiry

We may observe in different individuals a considerable variation in the proportional developement of different parts of the brain. It is reasonable to suppose, that the functions which are more developed in one person than in others, will be more active, and manifest themselves with more energy, than those which are less developed. Those which are comparatively small we may expect to be less active, and their powers more feebly exerted. Let us then select as the subjects of observation such persons as are marked by strong peculiarities of mind or character, and especially such as are endowed with a partial genius, as it is called; that is, who manifest in a very high degree any particular faculty of mind: let us note the peculiarities in the form of their heads, and observe what organs in them are of an unusually large size. By repeated comparisons we shall arrive at the knowledge of the particular organ in which that faculty resides. The converse method, on the other hand, must be pursued with those who betray a singular deficiency of power in any faculty. With such persons we must endeavour to discover what particular part of the brain exhibits an imperfect developement. The results of both these modes of determining the functions of each organ, when compared together, will correct, and, if just, will ultimately corroborate each other. Experience, multiplied and extended, will finally confirm and establish our conclusions, and complete the system in all its parts.

Correspodence in shape between the skull and brain.

But the living brain can never be exposed to observation, and, from the nature of its substance, loses much of its form and texture soon after death. It may appear impossible to discover the form or size of particular parts of the brain during life, since the whole mass is inclosed in the bony case of the skull, of which the thickness varies in different parts; and since the skull itself cannot be immediately inspected, being covered by muscles and integuments, which, by contributing to smooth all the inequalities of its surface, must preclude us from forming an exact estimate of its real shape. This obvious objection to the proposed inquiry, Drs. Gall and Spurzheim labour to remove by the following considerations. If we attend to the successive stages of the growth of the skull, we find that its ossification begins at different points; and the bony processes extend in divergent lines, adapting themselves exactly to the form and size of the cerebral parts they are destined to inclose and protect. Whatever violence may be done to the bones of the skull during birth, they soon return to their natural state, partly from their elasticity, and partly from the inherent powers of the brain, which tend constantly to restore its original shape. The compression of the brain is besides of too transient a nature to produce any permanent change in the primitive forms either of the skull or of the brain. If it ever amounted to what could irrecoverably derange the organization, and hinder its future developement, the necessary consequence of such a degree of violence would be death or idiocy.

In the progress of its growth, the increasing dimensions of the skull keep pace with those of the brain. All the cerebral parts do not increase simultaneously; and this partial developement is equally observable in the skull. The forehead, for instance, which at birth is narrow and flat, grows wider and more prominent from the age of three months to that of eight or ten years. After this period, the middle part of the forehead is less developed in proportion to the other parts. The neck of the child is very small, because the cerebellum, which is situated at the inferior occipital *fossæ*, is not yet developed; but in proportion as this organ increases in size, the skull grows prominent at that part. The same happens with all the other cerebral parts which increase progressively. The shape of the skull cannot be in any degree influenced by external causes, such as occasional pressure in one direction, as happens in carrying burdens on the head, or artificial modelling of the heads of infants, as is asserted to be practised among the Caribs and other savage nations. In other parts of the body we may remark, that whatever soft parts are inclosed in bones, the shape of the latter is adapted to the dimensions of the former, and is regulated by the changes they undergo; the ribs, and even the spine, yield to the pressure of an abscess, or the enlargement of an aneurism; and the bones of the face, in like manner, make way for the increase of tumours, and adapt themselves to the new form these render necessary. By experience in feeling the living head, we may readily learn to distinguish the form of the bones which lie beneath the integuments. The observation of the shape of the skull, or of the head, is therefore capable of giving us exact information as to the relative size and shape of the different parts of the brain, and on the knowledge thus obtained is founded the art of CRANIOSCOPY.

Practical cautions.

In practising this method, however, it is necessary to guard against several sources of error. We must take into account several protuberances, which belong to the natural state of the skull, and which had some particular destinations foreign to the immediate functions of the brain; such as the mastoid processes behind the ears, the crucial spine of the occiput, the zygomatic processes, and the frontal sinuses. The cerebral parts, situated behind the orbits, indeed, require some exercise on the part of the organoscope, in order to be exactly determined. The developement may be perceived by the configuration and position of the eyes, and by the circumference of the orbits. It is therefore necessary to examine whether the eyeball is prominent or hidden in the orbit, whether it is depressed or pushed sideward, inward, or outward. According to this position of the eyeball, we may judge that such or such parts of the brain, which is situated against such or such part of the orbit, is more or less developed. The functions of those organs, which lie wholly at the basis of the brain, can be ascertained only by examination after death.

It may be objected, that the organs are not confined to the surface, or convolutions of the brain; but although this be the case, and although they really extend from the surface to the basis of the brain, or *medulla oblongata*, yet the degree in which they are expanded at the surface, where they form the convolutions, will indicate, in general, the relative magnitude of the whole organ. The analogy of the five senses, of which the peripheric expansions indicate the developement of their respective nerves, shews the reasonableness of this supposition. From a large eye, implying a large retina, or peripheric expansion of the optic nerve, we naturally infer that the nerve itself is of considerable magnitude: may we not draw the same conclusion with regard to the organs of the moral sentiments and intellectual faculties, whenever we find that the convolutions, which are their peripheric expansions, are much developed?

In feeling for the organ, Dr. Gall recommends the use, not of the fingers, but of the middle of the palm of the hand; and declares that habit, as well as a certain natural delicacy of tact, is necessary to qualify a person to make these observations with certainty of success. We are warned, also, to confine our observations to young and grown-up persons in the flower of their age; for at an advanced period of life the brain diminishing by degrees, and retiring from the skull, leads to the recession of its inner table, and consequent inequality in its thickness, which renders it impossible to judge exactly of the size or shape of brain from that of the head. Analogous changes occur in the skulls of some lunatics, and occasion similar difficulties in applying the rules of cranioscopy. It is also to be considered, that our aim is to distinguish the size, and not the mere prominence of each organ. If one organ be much developed and the neighbouring organ very little, the developed organ presents an elevation or protuberance, but if the neighbouring organs be developed in proportion, no protuberance can be perceived, and the surface is smooth.

We have already stated the mode in which Dr. Gall proceeded to apply and to verify these principles; it is now time that we should present our readers with the result of his labours.

Classification of faculties.

He arranges the faculties of the mind, with their corresponding organs, according as they relate to the feelings and to the intellect: the first class comprehending the *propensities*, all which are common to men and animals, and the *sentiments*, which constitute what the French denominate *l'ame*, and the Germans *gemüth;* and the second class comprising the faculties by which we acquire knowledge, or the *knowing faculties*, as he terms them; and also the *reflecting faculties*, which last compose what the French call *l'esprit*, the Germans *gheist*, and what we should generally understand by the term *intellect*. He finds that the organs of those faculties which men possess in common with animals, are situated towards the basis and back part of the brain; while those of the superior faculties, which are peculiar to man, are placed somewhat higher; and the organs subservient to the intellectual faculties occupy exclusively the forehead. The total number of special faculties is thirty-three, as may be seen by the following enumeration.

Organs of, 1. Amativeness.

1. Of the faculties common to men and animals, the first is that physical propensity which has for its final purpose the continuance of the species. The cerebellum, a part which occupies the lowest situation in the encephalon, is affirmed to be the organ, the actions of which give rise to this propensity. Accident led Dr. Gall to this discovery, by his noticing the size of the back of the neck in a lady whose character, in respect to this passion, was not equivocal: and subsequent observation on an extensive scale, both in the human subject and in the lower animals, have abundantly confirmed him in his opinion. The following are the leading arguments on which he has rested it. First, the great size of the organ indicates the importance of the function to which it is subservient, and there is no cause, except the existence of such an organ in the brain, that is adequate to account for this propensity. The function of copulation takes place only in those animals which have a nervous mass or cerebellum. Throughout the whole class of quadrupeds, the neck of the male is thicker than that of the female, as may be observed particularly in the bull, the ram, and the stallion. It is also remarked that vigorous pigeons are distinguished by the size of their necks.

The developement of the cerebellum is simultaneous with that of the genital organs at the period of puberty, and early castration prevents its developement, as well as that of the beard, and the organs of the voice. Wounds of the neck have been observed by Hippocrates to be sometimes followed by impotency. In other cases, however, they produce erotic excitement. Apollonius Rhodius, in speaking of the love of Medea, represents her as suffering a violent pain in the back of her neck. A case occurred to Professor Reinhold, at Leipsig, in which an excitement of the genital organs succeeded the introduction of a seton in the neck, in a boy who laboured under ophthalmia. Spirituous frictions on the neck in hysterical fits are very useful. Lastly, the position of the cerebellum is supposed to prove its destination. After hunger and thirst, no function is more necessary than that of propagating the species. This function is the most common in animals after nutrition, and the cerebellum is in the inferior part of the head. Hence it is probable, that it is destined to the propensity of propagating, or that it is, as Dr. Spurzheim expresses it, the organ of *amativeness*.

2. Philoprogenitiveness.

2. *Philoprogenitiveness*, or the love of progeny, the στοργη of the Greeks, has its seat in those convolutions of the brain situated immediately above the hind part of the tentorium, and corresponding, therefore, on the outside of the skull with the crucial spine of the occiput. Dr. Gall had observed a distinct protuberance on this part of the head in women, and comparing the skulls in his collection, found a similar elevation on the skulls of children, and on those of monkies. During five years he was in search of a faculty that was common to all the subjects of those observations, and was in the habit of suggesting this difficulty to his auditors. At length a clergyman who attended, observed that monkies have much attachment to their progeny. The Doctor pursued this idea, and found that it applied perfectly to the observed appearances, as the developement of this part coincided always with the energy of this propensity. In animals it is generally larger in the females than in the males of the same species. This rule holds good in the human subject, although it is liable to occasional exceptions; for there are men who manifest the strongest propensity to associate with children, and in whom we accordingly find this organ larger than in the generality of women. In negroes we find this organ more prominent than in Europeans. In the cuckoo, the crocodile, and other animals to whom nature has not appointed the office of rearing their progeny, this organ is extremely defective. The crime of infanticide is more likely to be perpetrated by mothers in whom this organ is deficient in size; and accordingly out of 29 women who were guilty of this crime, Dr. Gall found 25 who had this organ extremely small. On the other hand, a female, who, being seized with delirium during child-birth, imagined that she was pregnant with five children, was found to have this organ unusually large. It must, no doubt, have been of gigantic dimensions in the lady, who, stricken by the curse of the gipsey whom she had refused to relieve, was impressed with the belief that she was about to give birth to as many children as there are days in the year.

3. Inhabitiveness, or Concentrativeness.

3. The organ of *Inhabitiveness*, or the propensity which some animals, such as the chamois and the wild-goat, have to inhabit high situations, is placed still higher in the occiput than the former, in a line proceeding towards the top of the head. In animals of the same species which live in low countries, we do not meet with an equal degree of protuberance in this part of the brain, as is observable in those which prefer living in elevated and mountainous districts. This is seen even in the rat, some varieties of which choose for their dwelling corn-lofts or the higher parts of a house, while others prefer living in the cellars. This faculty is not very active in man; but Dr. Gall conceived that it was in him allied to pride and haughtiness. Dr. Spurzheim, however, disclaims this doctrine; as he thinks it impossible to confound the "instinct of physical height" with the moral sentiment of self love and pride. Mr. Combe, conceiving that this organ has a more extensive sphere of action, and that it confers the power of being conscious of every thing going on in the mind, and of concentrating the attention, terms this power *Concentrativeness*.

4. Adh
siveness.

4. The organ of *Adhesiveness*, or the propensity to attach ourselves to persons, animals, or other objects, is situated on each side of the former, immediately under the *lambdoidal suture*, and gives a fullness to the lateral and posterior part of the head. This organ is the source of friendship, moral love, society, marriage, and attachment of all kinds. Dogs have it in an eminent degree, especially those races whose fidelity and constancy are characteristic, as the terrier, spaniel, and lap-dog. It is less prominent in the butcher's dog, greyhound, and mastiff. It was very large in a notorious highwayman at Vienna, distinguished equally as a robber and a friend, and who chose rather to die than to betray his confederates.

5. Com
tivenes

5. *Combativeness*, or the propensity to fight, results from the operation of an organ, situated immediately behind the ears on each side, at a part corresponding to the posterior inferior angle of the parietal bone, and behind the mastoid process. It is the seat of anger, as well as of pugnacity; and its locality is fully established, in Dr. Gall's estimation, by an extensive series of facts. His first discovery of the seat of this faculty, was from his observation of the head ot the Austrian General Wurmser; and it was subsequently confirmed by the experiments we have already mentioned which he made on boys he had collected from the street. The breadth of the occiput is a criterion of the spirit and courage of horses, dogs, &c. The bull-dog and pug-dog are in this respect superior to the mastiff. The hyæna is strongly contrasted with the hare, and the guinea-hen with the robin red-breast.

6. Destr
tiveness.

6. *Destructiveness*, or the propensity to destroy in general, but more especially to destroy life, has its seat just above the ears; the prominence of which part will account for the strange pleasure which some people take in killing or tormenting animals, in seeing executions, and for their inclination to commit murder. Among animals, this instinct for blood is strongly marked in the carnivorous tribes, especially in the lion, tiger, and others of the feline tribe; and the breadth of their skulls in this part shows us the great size of this organ, compared with that of their victims, the sheep, the goat, or the hare. The heads of murderers have in general been found to possess a visible prominence at this place. When the band of ferocious robbers and assassins, who so long infested the left banks of the Rhine, under Schinderhanns, had been caught, and a number of them executed, Dr. Gall found this organ strikingly developed in the heads of these banditti. This propensity is frequently strong in children, in idiots, and in madmen. Its object, in the lower animals, is evidently to procure the food on which nature destined they should live; yet some animals kill more than is necessary for their nourishment. In man this propensity presents different degrees of activity, from a mere indifference to the pain of animals, to the pleasure of seeing them killed or tortured, or even the most imperious desire to kill. Dr. Gall called this faculty *murder;* but Dr. Spurzheim thinks it produces the propensity to destroy in general, without determining the object to be destroyed, or the manner of destroying it. "It gives," says he, "the propensity to pinch, scratch, bite, cut, break, pierce, devastate, demolish, ravage, burn, massacre, strangle, butcher, suffocate, drown, kill, poison, murder, and assassinate." It would seem, therefore, that this organ has a great deal to answer for.

7. Const
tivenes

7. *Constructiveness*, the propensity to build, or the disposition to the mechanical arts, is indicated by the developement of the brain at the temples. Dr. Gall found this to be the case in great mechanicians, architects, sculptors,

and designers; and also in the skulls of the beaver, marmot, field-mouse, and rabbit, which construct habitations. Hares, on the contrary, which lie in the fields, have this organ defective, although in general they resemble rabbits. He possesses the skull of a milliner of Vienna, who had a good taste, and understood perfectly the art of changing the forms of her merchandises; in this skull the organ in question is prominent. It is by means of this faculty that birds build nests, savages huts, and kings palaces. It produces also fortifications, ships, engines of war, manufactures of all kinds, furniture, clothes, toys, &c. There was a lady at Paris, who, every time she was pregnant, felt the greatest propensity to build. The excessive size of this organ may lead a man to ruin his family by building, or to coin false money.

8. *Covetiveness*, or the propensity to covet, gather, and acquire, without determining the object to be acquired, or the manner of acquiring it, has its organ situated at the temples, on the anterior inferior angle of the parietal bone. This faculty gives a desire for all that pleases; money, property, animals, servants, land, cattle, or any thing upon earth. It produces egotism and selfishness, and may, when abused, lead to usury, plagiarism, fraud, or theft. The instinct of stealing, it is asserted, is not always the effect of bad education, of poverty, idleness, or the want of religion and moral sentiment. This truth, says Dr. Spurzheim, is so generally felt, that every one winks at a little theft committed by rich persons, who in other respects conduct themselves well. Mr. Combe terms this faculty *Acquisitiveness.*

9. The organ of *Secretiveness*, or the propensity to conceal, or to be clandestine in general, is situated in the middle of the side of the head, above the organ of the propensity to destroy. Dr. Gall first observed this organ in a person who had many debts, but who had the address to conceal his real situation, so that the creditors could have no knowledge of each other. He ascribes to this faculty cunning, prudence, the *savoir faire*, the capacity of finding means necessary to succeed, hypocrisy, lies, intrigues, dissimulation, duplicity, falsehood; in poets, the talent of finding out interesting plots for romances and dramatic pieces; and finally, the quality of slyness in animals, as in the fox and the cat, who conceal their intentions, and are clever in hiding themselves.

To the second genus of the order of feelings, namely, Sentiments, belong the following faculties:—

10. *Self-love, or self-esteem.* Dr. Gall first noticed this organ, which lies in the middle of the upper posterior point of the head, in a beggar, who stated that he was reduced to his present condition by his pride, which made him neglect his business. The animals endowed with this organ are the turkey-cock, peacock, horse, &c. Dr. Gall thought this organ is the same as that of the faculty which makes certain animals dwell upon mountains; but Dr. Spurzheim, as we have already observed, draws a line of distinction between them. The two great activity of this faculty is the cause of various abuses, as pride, haughtiness, disdain, contempt, presumption, arrogance, and insolence. The want of it disposes to humility. It is said to be more active in women than in men, and that its excess is sometimes the cause of madness.

11. *Love of Approbation.* Persons fond of the good opinion of others, have the upper posterior and lateral part of the head much developed. This may be called the organ of ambition or vanity, according to the object, which may be of various kinds. A coachman endowed with this faculty is pleased if his manner of conducting horses be approved; and a general is elated if he be applauded by his nation for leading his army to victory. This faculty is more active in women than in men, and even in certain nations more than in others. More women become mad from this cause than men.

12. Organ of *Cautiousness.* Two persons at Vienna were known to be remarkable for their extreme irresolution. One day, in a public place, Dr. Gall stood behind them, and observed their heads. He found them extremely large on the upper posterior part of both sides of the head. Hence he derived the first idea of this organ. Circumspect animals also, as the stag, roe, pole-cat, otter and mole, and those which place sentinels to warn them of approaching danger, as the chamois, cranes, starlings, and bustards, have this cerebral part much developed. This faculty produces precaution, doubts, demurs; and, in general, exclaims continually "*take care.*" It considers consequences, and produces all the hesitations expressed by the word *but.* When excessive, it produces uncertainty, irresolution, unquietness, anxiety, fear, melancholy, hypochondriasis, and suicide. Dr. Gall finds this organ more strongly marked in children than in grown persons.

13. Benevolence.

13. The organ of *Benevolence* in man, or of *meekness* in animals, is situated on the superior middle part of the forehead. In most animals it is restrained to a passive goodness; but in man its sphere of activity is very considerable, producing all the social virtues, or in one word, *Christian charity.*

14. Veneration.

14. The organ of *Veneration*, or of *Theosophy*, occupies the centre of the uppermost part of the *os frontis*. Dr. Gall had observed in churches, that those who prayed with the greatest fervour were bald; and that their heads were much elevated. The pictures of saints show the very configuration which he had thus noticed in pious men; and the head of our Saviour, also, is generally represented of this shape. It is by this faculty that man adores God, or venerates saints, and persons and things deemed sacred.

15. Hope.

15. The organ of *Hope* is situated on the side of that of veneration. Dr. Spurzheim considers the sentiment of hope as proper to man, and as a sentiment necessary in almost every situation; it gives hope in the present, as well as of a future life. In religion it is called faith. Its excessive developement produces *credulity.*

16. Ideality.

16. *Ideality*, or the poetical disposition. The heads of great poets are enlarged above the temples, in an arched direction. The sentiment inspired by this organ is the opposite of circumspection; it renders us enthusiasts, while circumspection stops our career by saying "take care." If the part of the head above this organ, and a little backward from it, be very much developed, the person is disposed to have visions, to see ghosts, and to believe in astrology, magic, and sorcery.

17. Righteousness, or Conscientiousness.

17. The faculty of *Righteousness*, or *Conscientiousness*, which produces the sentiment of just and unjust, right and wrong, has its organ situated a little more forward than the organ of approbation. It produces the sentiment of duty, and constitutes what is called conscience or remorse. Dr. Spurzheim admits farther an organ of *justice*, which he seeks for on the side of the following organ.

18. Determinateness, or Firmness.

18. *Determinateness*, or *Firmness.* Dr. Gall observed that persons of a firm and constant character have the top of the brain much developed. Lavater had made the same observation. This faculty contributes to maintain the activity of the other faculties by giving constancy and perseverance. Its too great activity produces infatuation, stubbornness, obstinacy, and disobedience. Its deficiency engenders fickleness and inconstancy.

To the order called Intellect, and the first genus of that order, viz. the *knowing faculties*, belong the following species:

19. Individuality.

19. *Individuality*, or the faculty which procures us the knowledge of external beings, after we have received impressions from them by the external senses, occupies the middle of the lower part of the forehead. Dr. Gall found this part very prominent, indicating a great developement of the anterior and inferior part of the brain, in all persons, who, from their extensive, but superficial knowledge in the

arts and sciences, were capable of shining and taking a lead in conversation. It has been not unaptly, though satirically characterized as the *blue-stocking* faculty. Tame animals have the forehead more developed than wild ones, and are more or less tameable in proportion as the forehead is more or less developed; Dr. Gall, therefore, calls this organ that of *educability*. Dr. Spurzheim, however, objects to this term, and has substituted that of individuality; he also remarks that the organ is early developed in children, because they are obliged to acquire a knowledge of the external world.

20. Form. 20. The organ of *Form* leads us to take cognizance of the forms of objects, with the existence of which the preceding faculty had made us acquainted. Persons endowed with it in a high degree, have a great facility of distinguishing and recollecting persons; they are fond of seeing pictures, and if they make collections, they collect portraits. Crystallography is the result of this faculty. The conception of smoothness and roughness also belongs to it. This organ is placed in the internal angle of the orbit, and, if much developed, it pushes the eyeball toward the external angle, that is, a little outward and downward. The Chinese appear to have it in perfection.

21. Size. 21. *Size.* After the existence and figure of any body, the mind considers its dimensions or size, for there is an essential difference between the idea of size and that of form. The organ must therefore be different; it is probably however in the neighbourhood of the former.

22. Weight. 22. *Weight.* The ideas of weight and resistance, density, softness and hardness, cannot be attributed to the sense of feeling, and require, therefore, a particular faculty for their conception. Its organ must be situated in the vicinity of the two last.

23. Colour. 23. *Colour.* The faculty of conceiving colour is, in like manner, totally distinct from the sense of vision, or the faculty of perceiving light. Its organ is placed in the midst of the arch of the eye-brows, giving them, when expanded, a vaulted and rounded arch. This configuration is characteristic of painters, and is strikingly displayed in the Chinese, who are well known to be very fond of colours. This faculty is generally more active in women than in men.

24. Space, or locality. 24. *Space*, or *Locality*. The faculty of local memory, by which we recollect localities, and find our way to places where we have been before, is much stronger in some persons than in others. Animals are also endowed with it, and it enables them to return to their dwellings and their progeny, when obliged to leave them in search of food. It is conspicuous in some dogs; while others are very deficient in this respect. The migration of birds is the result of this faculty. The pictures and busts of great astronomers, navigators, and geographers, as of Newton, Cook, Columbus, &c. present a great developement of this organ, which is situated under, but extends a little beyond, the frontal sinuses. The swallow, the stork, and the carrier-pigeon, have all this organ. This faculty conceives the places occupied by the external bodies, and makes space not only known to us, but inspires a fondness for this kind of knowledge. It makes the traveller, geographer, and landscape painter; it recollects localities, judges of symmetry, measures space and distance, and gives notions of perspective.

25. Order. 25. *Order.* This faculty enables us to conceive order. It gives method and order in arranging objects as they are physically related. Its organ is probably situated outward, but not far from the organs of size and space.

26. Time. 26. *Time.* Ideas of time are the result of a distinct faculty; for they may exist without those of order and number. They seem to be higher in the scale, and their organ, accordingly, occupies a higher place in the brain.

27. Number. 27. *Number.* All the ideas that are concerned about unity or plurality, that is, about number, belong to a faculty whose organ is situated in a part of the brain near the external angle of the orbit. The object of this faculty is calculation in general. When much developed, the arch of the eye-brows is considerably depressed, or is elevated at the outer extremity. This conformation is apparent in the portraits and busts of great calculators, as Newton, Euler, Kaestner, Jedediah Buxton, and Pitt. The heads of negroes are very narrow at this part; and, in general, they do not excel in this faculty.

28. Tu 28. *Tune.* The perception of musical tone is distinct from that of sound, and implies a different faculty from that of hearing. Its organ is placed on the lateral parts of the forehead. Its form varies according to the direction and form of its convolutions. In Gluck and Hadyn, it has a pyramidal form; in Mozart, Viotti, Zumsteg, Dusseck, and Crescentini, the external corners of the forehead are enlarged but rounded.

The heads and skulls of singing birds, especially the males, exhibit this organ fully developed. Monkeys are absolutely destitute of it.

29. Lan guage. 29. *Language.* The organ of the faculty of learning the artificial signs for the operations of the mind, of perceiving their connection with the thing signified, and of remembering them, and judging of their relations, occupies a transverse situation in the midst of the knowing faculties, and presses upon the basis of the orbit of the eye, so as to project the eye forwards when much developed. This produces what is commonly called a goggle-eye, denoting strong verbal memory. Sometimes the eyes are not only prominent, but also depressed downward, so that the under eyelid presents a sort of roll, or appears swollen. Such persons are fond of philology, that is, they like to study the spirit of different languages.

The second genus of the order Intellect, viz. the reflecting faculties, contains the following species:—

30. Co parison. 30. *Comparison.* This faculty compares the sensations and ideas of all the other faculties; and points out their difference, analogy, similitude, or identity. Dr. Gall observed various persons, who, in every conversation, had recourse to examples, similitudes, and analogies, in order to convince others; and seldom to reasoning and philosophical arguments. In them he found, in the midst of the superior part of the forehead, an elevation which presented the form of a reversed pyramid, and he named this organ, according to its functions, the organ of analogy. Nations who have this faculty in a high degree are fond of figurative language.

31. Ca lity. 31. *Causality.* This faculty examines causes, considers the relations between cause and effect, and always prompts men to ask, *Why?* Persons fond of metaphysics have the superior part of the forehead much developed and prominent in a hemispherical form, as Mendelsohn, Kant, Fichte, and others. The ancient artists have given to Jupiter Capitolinus a forehead more prominent than to any other antique head.

32. W 32. *Wit.* Persons who have this faculty, who write like Sterne, Voltaire, Piron, &c. have the superior external parts of the forehead elevated. The essence of this faculty consists in its peculiar manner of comparing, which always excites gaiety and laughter. Jest, raillery, mockery, ridicule, irony, &c. are its offsprings.

33. In tion. 33. *Imitation.* Persons who have a considerable elevation of a semi-globular form at the superior part of the forehead, have the faculty of imitating, with great precision, the gestures, voice, manners, and, in general, all the natural manifestations of men and animals. They have a disposition to be actors, and are prone to gesticulation. This organ is, in general, more developed in children than in adult persons.

To the above catalogue of the organs enumerated by Dr. Spurzheim, Mr. Combe has since added the two following, namely, 3 Won- de

34. The organ of *Wonder*, (situated immediately above *Ideality*, in the lateral parts of the anterior regions of the vertex,) which occasions the belief in the reality of ghosts, and other mysterious apparitions and visitations, and inspires a love for all that is marvellous and supernatural, and also a taste for novelty and fashion. When largely developed, it excites young men, born and bred in inland situations, to choose the sea as a profession.[1]

35 ventu- al

35. The organ of *Eventuality*, which, when large, gives prominence or a rounded fulness to the middle of the forehead. "The function of this faculty is to take cognizance of changes, events, or active phenomena, indicated by active verbs. In such expressions as the ROCK *falls*, the HORSE *gallops*, the BATTLE is *fought*, the substantive springs from Individuality, and the verb from Eventuality. It prompts to investigation by experiment, while Individuality leads to observation of existing things. Individuality gives the tendency to personify abstract ideas, such as Ignorance and Wisdom; and Eventuality to represent them as acting. An author in whom Individuality is large, and Eventuality small, will narrate actions, but deal little in physical description."[2]

Two other primary faculties are mentioned by Mr. Combe; one, which he terms *Alimentiveness*, or the desire of eating and drinking; and another, which had been called by Spurzheim *Vitativeness*, or the *Love of Life*; but the seat of these powers has not been exactly determined.

A lica- tic of the dc ine.

Excepting in the case of idiots, all the thirty-five organs above described are possessed by every person, but they exist in greater or less perfection in different individuals. Peculiarity of character is the result of irregularity in the original structure, or inequality in the relative developement of the several organs; circumstances which, according as they are diversified, lay the foundation of every excellence, as well as constitute the fatal sources of vice and depravity. These doctrines should, however, by no means be understood as lending their sanction to the latter; for crimes are considered as flowing from the abuse of certain faculties, and as still requiring for their prevention the counteracting influence of morality, and the salutary coercion of law. It must be of importance to every individual to know, if such knowledge be attainable, what is the degree of energy of the propensities and other faculties with which he may have been naturally and originally endowed; because every organ and corresponding faculty may be invigorated by proper exercise. The business of education will accordingly consist in exciting or restraining their developement, according to their natural deficiency or exuberance. Phrenology, by pointing out what are the strongest faculties in a child, will enable us to adopt the best plan of intellectual, as well as moral discipline; will assist us in regulating his passions, and maintaining a due balance between all his moral sentiments; and guide us in the choice of a profession for our pupil, conformable to the particular bent of his genius. "What benefit would arise to society," says Mr. Forster, the zealous advocate of these doctrines, "should we be enabled to make a just election of objects in youth, to be placed in situations capable of ripening their naturally energetic faculties. Phrenology will lead to important considerations regarding criminal punishment, particularly in houses of correction. It will enable us to distinguish, not only between those who have naturally strong evil propensities, from those whom distress or other contingencies may have hurried on to crime, but will point out the particular nature of the evil propensities to be corrected." It will also tend, he conceives, to establish important distinctions between different kinds of insanity, and enable us to discover the treatment appropriate for the cure of each. Lastly, it may prepare the way to a radical improvement of the human race, by pointing out those conformations of the head which it is desirable to eradicate or to perpetuate, and which should therefore be avoided or preferred in the choice of marriages. "It is certainly a pity," says Dr. Spurzheim, "that, in this respect, we take more care of the races of our sheep, pigs, dogs, and horses, than of our own offspring."

Objections to this system.

Such is the body of doctrines, and such the reasonings in their support, which have emanated from the school of Gall and Spurzheim, and which they have dignified with the appellation of a new science. A host of opponents, as might be expected, have arisen against a system so much at variance with common notions, leading to conclusions so remote from vulgar apprehension, and admitting so easily of being held up to ridicule by partial or exaggerated statements. We have already noticed the objection founded upon its supposed tendency to favour materialism, and shall pass over others of a similar nature, which proceed upon the presumption of a greater knowledge of the laws of the creation than we really possess, or which are derived from imperfect or mistaken views of the theory itself. We shall also refrain from employing the weapons of ridicule against a system so vulnerable to its attacks, and which would have been so capable of affording Swift a new incident for the history of the philosophers of Laputa. The simple exposition of the sandy foundation on which it has been built, of the flimsy materials of which it has been composed, and the loose mode in which they have been put together, will suffice to enable our readers to form their own conclusions as to the soundness and solidity of the edifice.

No particular part of the brain necessary.

It is, in the first place, obvious, that nothing like direct proof has been given that the presence of any particular part of the brain is essentially necessary to the carrying on of the operations of the mind. The truth is, that there is not a single part of the encephalon, which has not, in one case or other, been impaired, destroyed, or found defective, without any apparent change in the sensitive, intellectual, or moral faculties. Haller has given us a copious collection of cases, which bear upon this point; and a similar catalogue has been made by Dr. Ferriar, who, in a paper in the fourth volume of the *Manchester Transactions*, has selected many of Haller's cases, with considerable additions from other authors. The evidence afforded from this mass of facts, taken conjointly, appears to us to be sufficient to overturn their fundamental proposition. This evidence is not impeached by the feeble attempts of Dr. Spurzheim to evade its force, by a general and vague imputation of inaccuracy against the observers, or by having recourse to the principle of the duplicity of each of the cerebral organs; a principle of very dubious application, on a subject of so much uncertainty as the physiology of the brain. Poor, indeed, must be his resources, when we find him resorting to the following argument, in proof that the brain is the organ of thought, namely, that "every one feels that he thinks by means of his brain." We doubt much if any one has naturally that feeling.

Analogical arguments combated.

It requires, also, but a slight attention to perceive, that the very ground-work on which the whole of the subsequent reasoning proceeds, namely, that the different faculties of the mind are exercised respectively by different portions of the brain, is in no respect whatever established. The only arguments in its favour which bear the least plausibility, are derived from analogy. Now, analogy, in reasoning concerning the unknown operations of nature, is, at best, but slippery ground; and when unsupported by any other kind of evidence, cannot lead to certain knowledge, far less constitute the basis of an extensive system. The utility of analogical deductions as to what takes place in one department of nature, from our knowledge of what occurs in another, consists chiefly in their affording indications of what may possibly happen, and thus directing and stimulating our inquiries to the discovery of truth by the legitimate road of observation and experiment. But to assume the existence of any such analogy as equivalent to a positive proof, resulting from the evidence of direct observation, is a gross violation of logic. Yet it is upon assumptions of this kind that Drs. Gall and Spurzheim have ventured to found all the leading propositions of their doctrine. In the secretions of the body, they observe, the preparation of different fluids is consigned to different glands, having different appropriate structures; and they consider this analogy as a demonstrative proof of what happens in the operations of thought, and the phenomena of the passions, which, because they differ as much in their nature as milk does from gall, must, accordingly, be the result of actions in different portions of the brain; which portions are, therefore, to be regarded as so many different organs, rather than as parts of one organ. Even in a case where all the analogies are favourable to one side of a question, such a loose mode of reasoning would be entitled to little confidence; but how fallacious must it not prove, when analogies can be pointed out which apply in the opposite direction? It requires no extensive knowledge of the animal economy to perceive, that modifications of functions equally diversified with those of the intellect, are, in many cases, the result of actions taking place in the same organ. Does not the same stomach digest very different and even opposite kinds of aliment? Yet we do not find that one portion of that organ is destined for the digestion of meat, and another for the digestion of vegetable matter; although the operations required for the conversion of such different ingredients into the same chyle, cannot possibly be the same. Nerves perform the double office of volition and sensation; but the different bundles of fibres which convey each impression, the one to the muscles, the other to the sensorium, are wrapped up in the same sheath, and are so intimately intermixed during their course as to constitute a single cord. The same organ serves for the hearing of acute and of grave sounds. The whole retina, and not merely different portions of its surface, receives the impression of different kinds of colour; there is not one organ for the perception of blue and another for the perception of red rays. Guided by such analogies as these, might we not be equally justified in concluding, that the same part of the brain may serve for the memory of words, as for the memory of things; and that the same portion of that organ which enables us to conceive the idea of figure, may also suggest to us that of size?

---

[1] *System of Phrenology*, fourth edition, p. 381.

[2] *Ibid.* p. 518.

The same doctrine of the plurality of cerebral organs, is endeavoured to be supported by another analogy, equally vague and loose with the former, namely, that the sense of fatigue from long continued muscular exertion, resembles, in its circumstances, the effects of long continued study on the mind, and is equally relieved, in both cases, by a change of action. To us, however, it appears, that this analogy might, with equal justice, have been adduced, as favouring the opposite view of the subject; for we can just as readily conceive the sense of fatigue to take place from the exercise of the whole organ in a particular mode, as from that of any part of the organ; and relief must equally, in both cases, be experienced from the ceasing of that action, or from the substitution of one of a different kind. The muscles admit only of one kind of action; and the energy which each derives from the nerves, when once exhausted, is not so readily replaced from the general stock belonging to the system. In the finer textures of the body, which approach more to that of the brain, the analogy not only fails of giving support to the doctrine, but has an opposite tendency. The same retina, when fatigued by the continued impression of a particular colour, is still as ready as before to receive the impression of another colour. The circumstance of partial fatigue with regard to one set of actions, may, therefore, exist, without implying the necessity of a separate organ for the performance of these actions. Indeed, if the brain have any laws similar to those of muscular motion, it must have a much greater number peculiar to itself, and all such distant analogies as those we have been considering, must be perfectly inconclusive. Similar observations will apply to the explanation of the phenomena of sleep, of dreams, of somnambulism, of partial losses of memory, and of insanity. It is equally conceivable, that they should result from the imperfect or differently modified actions of one organ, as from the separate activity of different parts of that organ, whilst the other parts are inactive. Analogies may be equally adduced in support of both sides of the question, and can certainly prove nothing on either.

Futility of anatomical proofs.

Drs. Gall and Spurzheim appeal with great confidence to anatomy, and particularly to their own anatomical discoveries, as affording a solid support to their doctrines. "We never," say they, "separate anatomy from physiology, for physiology without anatomy is unfounded; while anatomy without physiology is useless. A physiological system of the brain would necessarily be false, were it in contradiction with its anatomical structure." This conclusion, which at best is but a negative one, is totally inapplicable to the theories in question. The anatomy of the brain is so complex, and so void of apparent adaptation to any purpose we can understand, that it will suit any physiological system nearly equally well; at least it can never be adduced in contradiction of any hypothesis, however wild, that can be framed as to the mutual operation of soul and body. All that these anatomists have done, in this respect, is to show that there is no appearance of a common centre of departure or of a collection of nervous filaments. The separation of the parts of the brain and their diversity of shape, can no more be evidence of a diversity in their functions, than the multitude of distinct and separate lobules which compose the kidneys of birds, and of a great number of quadrupeds, are indications that each part performs a different office. Comparative anatomy, indeed upon which so much is made to hinge, is of all guides the most fallible in questions of this nature; since we behold, in numberless instances, a great variety of ways in which nature accomplishes the same function and the same purpose, in different departments of the animal creation. But on a comparison of animals with each other, it may even be doubted, whether there is any connexion or proportion observable between their intellect or inclinations and the number of parts in their brains.

The possibility of discovering the size and the shape of the different parts of the brain from the external examination of the head, is also discountenanced by anatomy. There are often considerable impressions on the interior of the skull, where the corresponding exterior surface does not exhibit the slightest appearance of projection, and is sometimes even depressed; and there are frequently large prominences without, where there are no corresponding concavities within; so that when the outer surface of the bony case is compared with a mould in plaster or wax of the cavity itself, they exhibit considerable differences, and, from the great variation which may take place in the thickness of the bones, this difference is not the same in degree in any two skulls.

Size of organs no criterion of energy.

Hollow as are the foundations of this theory, the materials which compose the superstructure will prove, on examination, to be still more frail and unsound. The whole fabric rests upon the validity of a single proposition, which in itself is extremely questionable, namely, that the size of an organ is in general a criterion of the energy with which its function is performed. If any doubt should remain as to its truth, the whole of the pretended discoveries relative to the functions of the several parts of the brain are shaken, and the fantastical edifice has no auxiliary prop to arrest its fall. So essentially, indeed, does the whole of this system depend upon the truth of a number of independent propositions, that if any one of them should turn out to be incorrect, the whole fabric must give way. The evidence in its favour, instead of being cumulative, is disjunctive. Where each proposition must be sustained by a separate series of proofs, as is the case here, it is evident that the chances of error must be multiplied in proportion to the number of steps we must ascend before we can arrive at the last conclusions. Let us, for example, examine the logic by which the above fundamental principle is deduced. "A large muscle," say they, "is stronger than a small one; and a large loadstone is more powerful in its attraction than a smaller one. Why should it not be the same with regard to the brain?" Thus again do they confide in a loose analogy, derived from another and a totally different part of the economy; and as if the organization and functions of the animal body were not sufficiently remote from the nature and operations of the human mind, the inanimate world is ransacked for the shadows of an analogy, which, when viewed through such a distance of intervening mist, may wear the semblance of reality. But the phantom must immediately vanish upon a near inspection. For the perfection of a refined and delicate instrument, such as must be that which is subservient to the operations of the intellect, innumerable conditions must concur; amongst which that of size, it is reasonable to suppose, is the least important. Delicacy of texture, fineness of organization, and harmony of adjustment between the several parts of its complex structure, must contribute infinitely more towards rendering it capable of performing its office, than superior magnitude; a circumstance which in itself is quite as likely to prove a source of imperfection, as to impart additional facility. Increase of size in the viscera of the body is often the indication of a diseased, instead of a healthy state. Small eyes, Professor Hufeland observes, see with more strength, and last longer than large eyes. Why may not this be also the case with the organs of the brain? But really, in our present state of ignorance as to the mode of operation by which they are subservient to the processes of intellect and sensation, all such reasonings *a priori* on their functions, as connected with their size, must be completely illusory.

P tical di ulties.

Even were we to admit so questionable a doctrine as that the energies of the parts of the brain are proportional to their magnitude, insuperable difficulties would still be opposed to the determination of their relative size in the living head; crowded as all these organs are in a narrow compass, and completely hid from our view by an irregular bony case which protects them from injury, and which is itself covered by a thick and variable layer of muscle and integument. Let us, however, for the sake of argument, suppose that the form of each organ within the skull can really be ascertained by external examination of the head; shall we allow it to be an easy task to determine the real character of the individual who is the subject of observation? Are we always able to discriminate between real and affected sentiment; or to mark with certainty the operation of all the various motives which constitute the springs of action? Is the transient glance of a passing observer sufficient for unravelling the complex web of our affections, or unveiling the secret and tortuous recesses of the human heart, so as to assign to each principle its precise sphere of agency? Can the most profound moralist, or acute metaphysician, pronounce with confidence what are the natural dispositions of any human being, knowing as we do, that these dispositions must have been changed or modified, exalted or subdued, perverted or refined, by the force of habit, education, example, and a multitude of other powerful causes, which, in his progress through life, have moulded his intellectual and moral constitution? Can he trace them through the guise of falsehood, artifice, and dissimulation, which so commonly hide his real character from the world, and which occasionally deceive the eye of the closest and most vigilant observer? Is it to the behaviour of a person who knows that he is watched; is it to the partial report of his friends; is it to the testimony of the individual himself, the most fallible of all, that the phrenologist is to trust for his knowledge of human character? Such, however, is the kind of *experience*, from which it appears that all the doctrines relative to the functions of the different parts of the brain have been derived; and it is in this experience, as in an impregnable fortress, that the adherents of the system make their last and most resolute stand. Quitting the airy region of theory, they fancy themselves posted upon a rock, secure against the insidious minings of scepticism, and bidding defiance to the rude assaults of argument. The appeal to the evidence of induction, as to the supreme authority in the court of philosophy, is made with confidence; and all the wild effusions of a bewildered fancy are presumed to be sanctioned by a supposed conformity with experience. You may speculate or reason, they exclaim, as you please; observation shows that such and such forms of the head, are the invariable concomitants of such and such predominant dispositions and faculties. Who will dare to set up his opinion in opposition to ascertained facts? We venture only to express strong doubts as to the reality of these facts, on which so much is made to depend, possessing the character of *general facts*, that is, of being the results of legitimate induction; and to suggest the expediency, previously to any admission of their truth, of inquiring not only into the manner in which the knowledge of these pretended facts has been obtained, and in which inductions from them have been made, but also into the talents and qualifications of the observer upon whose testimony we receive them for the exercise of this philosophical process. We should know in what spirit he conducted the inquiry; with what previous dispositions he examined the objects of his contemplation; what motives led him to these researches; and what interest he may have in the event. Experience, we should recollect, leads to very different results, according to the sagacity and good faith of the person who acquires it. Minds already prejudiced collect from it only a confirmation of their errors, and become, by its means, only the more obstinately wedded to their opinions. The sailor, steadfast in his belief that his whistling to the sea will raise a wind, or conjure up a storm, instead of being undeceived by experience, is only the more strengthened in his faith by the observations which it furnishes to him. In what a multitude of instances do we not find men deceiving themselves as grossly, when they draw inferences from what they see, if prepossessed with the expectation of meeting with a certain coincidence, or succession of events. How disposed are we all to disregard the exceptions to a preconceived rule, and to allow undue weight to every example that conforms to it. How willingly we repel the evidence that opposes, and how eagerly we catch at whatever corroborates our previous notions, especially when those notions have originated with ourselves, and are viewed as the darling offsprings of our own lucubrations.

Nature of the logic employed.

The discerning reader may already have perceived strong indications of this bias in the framers of the phrenological system, from the account we have already given of its origin and history, and of the kind of evidence on which they pretend to establish its doctrines. In order, however, to enable him to form a correct idea of the species of logic which they have been in the habit of employing and which they deem conclusive, and of the tone of mind with which they prosecute the investigation of subjects where nothing but the exercise of consummate prudence can secure from error, we shall conclude by offering one or two specimens of their mode of reasoning. We shall pass over the numerous stories, each more ridiculous than the preceding, of irresistible natural inclinations to wander from place to place, to commit murder, theft, infanticide, and other crimes, without any assignable object. We shall refrain from criticising the wonderful accounts of people who were insane on one side of the head only, and observed their insanity with the other side, and of others who heard angels sing, and devils roar, only on one side; nor shall we stop to investigate the curious case of the woman who declared in a court of justice, when accused of having destroyed her infant, that her sole motive for becoming pregnant was that she might enjoy the exquisite pleasure of killing her own child. Neither shall we venture to involve ourselves in that metaphysical labyrinth of the *thirty-five special faculties* into which they pretend to have analyzed the human soul; but content ourselves with examining, what in fact alone deserves examination, the sort of evidence brought forward to establish the relation between each faculty and a particular defined portion of the brain. We shall take, for this purpose, the following passage, which may be esteemed a fair specimen of the whole.

"Dr. Gall examined the head of a woman at Vienna who was known as a model of friendship. She suffered different changes of fortune; she became alternately rich and poor; but was attached to her former friends. Gall found the part of her head situated upward and outward from the organ of philoprogenitiveness, very prominent, and called it the organ of friendship. Our observations are not multiplied enough to enable us to decide positively on this organ; yet its seat appears to be more than probable. It *must* be inferiorly, because this faculty exists in the lower animals, and is a propensity. *For this reason* it belongs to their region of the head; and according to its mimical signs, and the motions of the head when it is active, it lies laterally and backward." Dr. Spurzheim, it is obvious, here reasons in a circle; for he assumes as true the thing to be proved, namely, that faculties of a certain class reside in a certain department of the head, and then applies it to establish the very proof on which the proposition itself ought to have rested. In order to render intelligible the latter part of his argument, the reader should be informed that Drs. Gall and Spurzheim believe, that, when any faculty of the mind is strongly excited, the action of the corresponding organ in the brain tends to raise that part of the head in which it is situated; so that the person has a propensity to lay his finger upon the nearest external part of the head, or sometimes to apply his hand to it, either to cool it when too hot, or to warm it when too cold, and that he is occasionally prompted to rub it in order to excite it when too sluggish. Thus, when we endeavour to recollect a name or a word, we unconsciously slap our foreheads, or rub the skin a little above the eyes, or perhaps higher still, just where the appropriate organ of memory is situated, that it may awake and exercise its peculiar faculty. When embarrassed by any difficulty, we gently stimulate in like manner, the organ of contrivance, by scratching the head at the part under which is the seat of *constructiveness*. The timid man scratches his head on the organ of courage behind his ear, as if he tried to rouse the feeble organ into activity. A proud man holds his head erect upon his shoulders, and raises himself upon his toes, for no other reason than because the organ of the sentiment lies at the very top of the head, and is therefore elevated by the action. A sense of danger, or the necessity of *circumspection*, leads all animals, man not excepted, to stretch their necks forwards horizontally, thus presenting the broad extent of that organ, as it were, in front. Devotion raises the head gently; and our adorations are all directed upwards, not because we regard the Deity as above, but because the organ of adoration is situated in the centre of the upper part of the head. When busied in deep contemplation, we cover the whole forehead with our hands, as it is there that the reflecting faculties are lodged; and, accordingly, when we reproach any one for his want of reflection, we put our hand to this part of the head; and exclaim, "he wants it here." If we try to recollect a date, we put into action the organ of time, which being situated over the eyebrows, and a little to one side, occasions an involuntary movement of the eyes upwards and towards the temples. In beating time to a musical air, we make the head oscillate from side to side, because the organs of tone as well as of time, being situated on each side, and being alternately in action, occasion these gesticulations. Sterne excelled in wit: and we find him represented in all his portraits with his head leaning on his hand, the fore-finger of which is placed on a particular part of the forehead. Dr. Spurzheim considers this as one of the proofs that the organ of wit occupies that very spot.

With minds capable of allowing any weight to such observations and imbued with such notions of the nature of philosophical induction, as are implied by the grave admission of such frivolous arguments as these, the investigation of the laws of nature must be an easy and a delightful task. With the abundant and all-powerful resources, which their indulgent method of reasoning is ever ready to supply, all difficulties may be smoothed away, all chasms immediately filled up, and all obstacles made to vanish the moment they arise. We need not be under any embarrassment at meeting with a skull exhibiting a particular prominence, although the faculty which should correspond to it be deficient. Doubtless the individual must have been strongly gifted by nature with this faculty, but education has long ago taught him to disguise or suppress its manifestations. It exists, perhaps, unknown to the person himself, and wants only a proper occasion for its being exhibited; or more probably the other faculties, having received a greater proportional developement, have overpowered and prevented it from appearing. If we find, on the contrary, a strongly marked faculty, without the corresponding shape of the head, we may still conclude that the organ exists notwithstanding; for the neighbouring organs, having received a greater extension, may have pushed it from its true place, or have grown up around it, and have concealed it from vulgar observation. Its not having been recognised is only a proof of want of skill in the observer; no doubt, it would easily have been discovered by the eye or hand of a true believer, and experienced cranioscopist; for it should be recollected that the differences are often very minute, and require the *tactus eruditus* for their detection. Besides, how can we be certain that the excellence of the faculty in question is not of an artificial or relative kind, and that it results from education, or the weakness of opposite faculties, rather than from nature? If all these expedients should fail us, we have nothing to do but to plunge into the depths of metaphysics, to refine and make subtle distinctions, or loosen the signification of a few words, till we have entangled ourselves in a wood, and lost sight of the real difficulty that had perplexed us. Thus will the theory be freed from all exceptions, and the induction be rendered complete. With such a convenient logic, and accommodating principles of philosophizing, it would be easy to prove any thing. We suspect, however, that on that very account, they will be rejected as having proved nothing.

Reply to criticisms

We have here re-printed the Essay on this subject which appeared under the head of Cranioscopy, in the Supplement to the last edition of the present work. We have done so because we have not seen any reason to alter our views. Since the year 1818, when that essay was written, replies have been attempted to some of our strictures; particularly by Mr. George Combe, in his "*Essays on Phrenology, and on the objections* *made against it,*" Edinburgh, 1819; and by Dr. Andrew Combe, in the *Phrenological Journal.* Although the conductors of this Journal have admitted that our Article was "regarded in the South as the most formidable attack Phrenology ever had to sustain,"[1] and have in so far paid us a compliment, we deem it unnecessary to answer, otherwise than very generally, their comments on the reasonings contained in it; because most of those comments are founded on a misconception of the scope of our arguments. When, for instance, we attempted to show, that, in establishing a philosophical principle, mere analogies ought not to be esteemed as equivalent to proofs, and when we maintained that they are still less to be relied on, when other analogies, of a contrary tendency, can be adduced on the other side of the question, we are represented by Dr. Combe as building our arguments on analogy, the very principle of which we were pointing out the fallacy, and repudiating the authority; and we are even charged with being guilty of the strange inconsistency of endeavouring to "refute direct inductive evidence, by that drawn from analogy."[2] Any reader who had paid the least attention to the train of reasoning we employed, must have perceived that our reasoning was diametrically the reverse of that which is imputed to us; and that we had even guarded against the possibility of mistake by the sentence concluding with the words, "all such reasonings *a priori* ...... must be completely illusory."

Arguments from human anatomy.

By the help of a mis-quotation, in which the qualifying adverb "nearly" is omitted, we are represented as having asserted, that the anatomy of the brain "will suit any physiological system equally well."[3] All the notions we can form of the nature of mental operations are so completely and essentially different from any of the affections of which we can conceive matter to be capable, that it is utterly impossible for us to understand the mode in which a connexion has been established between them; or to imagine any physical structure whatsoever, which shall, in the remotest manner, correspond with the metaphysical constitution of the soul. This, however, we may confidently assert, that amongst all the hypotheses which have been propounded respecting the correspondence between the corporeal instruments of the mind, and the mental faculties themselves, the one which is the least in accordance with the actual structure of the brain, is that devised by the phrenologists. Let a person, unacquainted with the anatomy of that organ, be shown the phrenological map of the cerebral regions, and let him be told, that to each corresponding subjacent portion of the brain is ascribed, as to a separate organ, a certain special mental function; one set of these organs being appropriated to the establishment of certain definite propensities, whilst another set gives rise respectively to various sentiments, and a third confers each its peculiar intellectual power; with what immeasurable surprise, on lifting up the bony covering which had concealed this expected assemblage of well defined organs, would he behold a uniform mass of pulpy substance, divided by furrows only, into serpentine but continuous convolutions, bearing no conformity or even similitude to the notions which his previous instructions had led him to form of distinct masses, divided from each other in accordance with their phrenological functions. Each of these pretended organs, far from being isolated in its structure, as its alleged isolated functions would imply, from the neighbouring parts, is seen to pass on, without visible boundary, to the next, by a continuity of cerebral substance. Turning round upon his instructor, would he not complain of being misled by him; and would he not require him to explain what intermediate function he can ascribe to those portions of the same convolution which occupy an intermediate place between two organs, to which he has already assigned functions utterly heterogeneous with one another? What lucid ideas can he convey of a function intermediate between *benevolence* and *imitation*, between *ideality* and *acquisitiveness*, between *cautiousness* and *adhesiveness*, or between *self-esteem* and *concentrativeness* or *inhabitiveness*, of which the respective organs are not merely contiguous, but pass insensibly into one another; and what is the curious and hitherto nondescript office that he will assign to those portions of the brain which occupy the central space at the junction of quintuple groups of organs, such as those of *ideality, acquisitiveness, constructiveness, tune,* and *wit,* all of which, though separated by the fancy of the phrenologist, have been by nature amalgamated into one continuous mass, undistinguishable by any visible lines of demarcation?

From comparative anatomy.

Not content with expressing his dissatisfaction at our failing to perceive the accordance between the structure of the human brain and the doctrines of phrenology, Dr. Combe extends his censure to our objection as to the evidence which observations on lower animals are supposed to afford in their favour; and to our assertion, that in the construction of their system "much was made to hinge" on facts derived from comparative anatomy. That the founders of the system placed great reliance on this kind of evidence, is a proposition sufficiently borne out by the testimony of Sir George Mackenzie, who, when speaking of inhabitiveness, remarks, "it is chiefly from observation on the lower animals that Dr. Spurzheim seems *to consider it as certain*, that there is such a faculty in man."[4] The fallacy of the reasoning by which comparative anatomy has been pressed into the service of phrenology, has been so ably exposed by Dr. Prichard, in his Treatise on Insanity, that we shall beg leave to borrow from that work the following judicious remarks. "The chief peculiarity," observes Dr. Prichard, "of Dr. Gall's psychological theory, was the attempt to draw a parallel between the animal qualities displayed by the lower animals and the individual varieties discovered among men." He proceeded "on the principle, that the innate or original faculties are common to man and the lower tribes of animals, to those at least which bear to man a general analogy in their organization, and especially in the structure of their nervous system; and sought for analogies in physical phenomena between the brute tribes, tracing in them the rudiments of those properties which, taken collectively, and in their highest degree of developement, form the human character, and which, in lower degrees and various relations, constitute the distinctive nature of each of the inferior kinds. The attempt was ingenious, and seemed to hold out the prospect of discovering curious and interesting relations; but it is necessary, before embarking in the inquiry, to determine whether the analogies are real or apparent; for it has been tacitly assumed that the supposed distinction between instinct and reason is unreal, and that the active principles are of the same kind in the higher and lower beings of the creation." "Perhaps metaphysical writers have been mistaken in laying down so broad a line of difference as they have established. We must, then, either elevate the brutes, or lower the superiority of mankind. Shall we say, after tracing the operations of a constructive instinct so wonderfully displayed by the beaver, or in the cells in which the bee lays up his honey, that an impulse to action precisely similar gave origin to the pyramids of Egypt, or to the building of Constantinople? Shall we venture to affirm that the tunnel under the Thames owes its existence to a burrowing propensity resembling that of the rabbit or the mole? Shall we conclude that Parry and Franklin sought the regions of the north, impelled by the instinct of the migratory rat; and that Magellan and De Gama traversed the Southern Oceans directed by an influence analogous to that which moves the flight of swallows? Or may we, with greater probability, determine that the lower tribes act under the guidance, not of blind instinct, but of enlightened reason; that metaphysicians were mistaken when they laid down the principle, 'Deus est anima brutorum,' that the birds of passage have some acquaintance with physical geography, and know the quarter where tropical warmth exists and genial breezes blow; that the bee has studied the exact sciences, and knows by calculation the form most advisable for its cells? In short, that there is a real analogy and correspondence between the mental faculties of man and the physical endowments of those creatures whom he conceitedly regards as his inferiors? If either of these positions can be maintained, there will be a sound foundation for the comparative pyschology of Dr. Gall and his followers; but if they should be rejected as improbable, we must admit that the analogies pointed out are remote, the things compared are different in kind, they agree only in external appearances; and we shall be brought to the conclusion that it has pleased the Author of nature to bring about corresponding results in the rational and irrational departments of the creation, by very different means."

[2] *Ib.* i. 168, 169.

[3] *Ib.* i. 166.

[4] *Illustrations of Phrenology,* p. 92.

"If the evidence," continues Dr. Prichard, "brought in support of the organological system depends so entirely on universal coincidence between psychical properties and corresponding varieties in the structure of the nervous fabric, it must be important to determine whether there are any departments of the animal kingdom in which instincts and motive habitudes, and an entire psychical nature are displayed analogous to those of vertebrated animals, while yet in these departments there is no structure which can be said to bear resemblance to the complicated cerebral system of the so termed higher animals. In all the vertebrated kinds, the organization of the nervous fabric is in one principle, and the same fundamental type, with different degrees of developement, is traced in man and all other mammifers, in birds, reptiles, and fishes; but here the resemblance terminates, and the nervous system of molluscous animals and insects presented but few and remote analogies to that which belongs to the first great branch of the animal creation. It is, indeed, to be presumed that the nervous system, taken as a whole, fulfils, in the tribes last mentioned, the same offices as in those animals who have it enclosed in a bony case. Still, nothing exists at all resembling the complicated formation of a brain, with its lobes and convolutions. It is so much the more surprising to find the higher instincts, which had almost disappeared in fishes, display themselves with new splendour and variety in the brainless insects; creatures which, in the wonderful imitations of intelligence that govern their motive habits, rival, if they do not even exceed, the sagacity of the animals which most approximate to man."

"Now, if it should be established, that all those properties of animal life, approximating to intelligence, or bearing analogies so striking to the manifestations of mind, which, in one great division of the animal kingdom are assumed to be essentially connected with, and depending on, a particular system of organization, exist in another department, and display themselves in all the same various profusion, while the creatures belonging to this latter department are yet destitute of that system of organization, and of any thing that bears the resemblance to it, the advocates of Phrenology will be obliged to abandon that broad ground on which they have attempted to fortify their position. Within the more confined field which the vertebrated tribes alone present, it will be more easy to maintain such an assumed connexion of physical properties with a peculiar structure; or, rather, it is more difficult to disprove it when assumed. The general analogy which prevails throughout these tribes in the organization of their cerebral and nervous system, affords no room for so decisive a contradiction to the relation which the phrenologists would establish. Yet even within this field great and striking facts display themselves which are adverse to the hypothesis. Birds and reptiles, as Jacobi has observed, are nearly, if not wholly destitute of many cerebral parts, which in mammifers are held as of high importance for the manifestation of psychical properties, and yet they display psychical phenomena similar to those of mammifers. Whenever an undoubted and tangible fact can be laid hold of in the different proportional developement of cerebral parts, which can be brought into comparison with the relative differences of animal instinct, or of psychical properties in general, there is, if I am not mistaken, a manifest failure of correspondence between the two series of observations. This has been shown by Rudolphi in a striking manner, with respect to the cerebellum. The cerebellum, as this writer has observed, is found to lessen in its proportional developement as we descend in the scale of organized beings, without any corresponding diminution, and even with an increase of the propensity which Gall connects with it. How remarkably powerful is this instinct in birds; and yet how small is the cerebellum in the feathered tribes compared with its size in mammifers, and even in the latter, when we consider the magnitude which it attains in the human species? We observe those tribes in which the cerebellum nearly or entirely ceases to exist, obeying, nevertheless, the impulsion of instinct as blindly or devotedly as other kinds which have the organ in question remarkably developed. When we consider the great amplitude which the cerebellum attains in man, in comparison with its size in lower animals, we are obliged, if we really attach any importance to such a system of correspondence, to acknowledge some relation between this circumstance and the transcendant superiority of the human intellect, compared with the psychical powers of brutes."

"The facts which suggest themselves as we follow these trains of reflection, are scarcely to be reconciled with the phrenological theory: they seem, in the first place, to show, that the relations which in it are assumed to prevail through all nature are subject to vast exceptions; and as one great proof of the doctrine is the assumed universality of such relations, or the endowment of psychical properties in coextension with certain peculiarities of structure in cerebral parts, the exceptions endanger at least the outworks of the whole doctrine. When, in a more limited survey, we confine our observation to the sphere of vertebrated animals, and discover that variations in psychical phenomena take place without any evidence of corresponding changes in the structure of cerebral parts, and that these changes, on the other hand, occur without such alterations as we are led to anticipate in psychical properties, the system of organology seems to be shaken to its very centre."[1]

The ind tion imp fect.

Whilst the defenders of phrenology have, on the one hand, misrepresented the minor points of our argument, they have, on the other, disguised from their readers that it is on the insufficiency of the evidence adduced in support of their doctrine, that we rest our main objection to its credibility. We maintain, that they have taken only a one-sided view of what nature presents to our observation; that they have paid attention to those facts alone, which are confirmatory of phrenology, and shut their eyes to those which oppose it. In order to establish what they consider as the rule, they have collected together all the instances in its favour, and have passed over or suppressed all the exceptions. What we assert is, that more enlarged inquiry, conducted with a more entire devotion to the cause of truth, and a scrupulous rejection of error, would have shewn the latter to be at least equal, if not superior in number to the former. Our own observations, as far as we have pursued them, have led us to this conclusion; and it was on the result of these observations that our scepticism was principally founded. So frequent, indeed, are the exceptions, that even the founders of the system, Drs. Gall and Spurzheim themselves, on applying it practically, committed, as is well known, very glaring mistakes; giving frequently the most false judgments of the characters of various individuals. Have these mistakes, we may ask, been any where recorded by the phrenologists, and candidly set off against the instances in confirmation of their sagacity? What avails their collections of thousands of examples of coincidences, when the perhaps equally numerous instances of discordance are excluded from the catalogue? The fact, that the brain of Cuvier was of unusual magnitude, has been triumphantly proclaimed in all the publications on phrenology; but we are not aware that any phrenologist has brought forward the equally well-certified fact, that the brain of Sir Walter Scott was found on examination to be "not large."[1]

---

[1] *Treatise on Insanity*, p. 465 to 474.

In like manner, a long catalogue of persons avowing their belief in phrenology, including many men of eminent talents and extensive knowledge, has been paraded before the public; but we have not yet seen any counter list of unbelievers prepared with the view of ascertaining, in a science professedly of pure observation, on which side the weight of authorities preponderates. The class of men who, from the nature of their pursuits, are perhaps best qualified to form a correct judgment in matters of this nature, are the members of the medical profession; yet how inconsiderable, compared with the total number, is the proportion of those belonging to that profession who, according to Mr. Combe's catalogue, have given in their adhesion. Sculptors, again, compose another class of men whose studies lead them more especially to the most minute and accurate knowledge of the external form of the human head; yet amongst the many who are at present engaged in the active exercise of their noble art, Mr. Combe has been able to bring forward the name of only one solitary individual as lending a countenance to phrenology.

Te mony adv e to phr ology.

"It is not enough," as Dr. Prichard very justly observes, "to have a few chosen coincidences brought forward by zealous partizans, who go about in search of facts to support their doctrine, and pass by, or really cannot perceive the evidence that ought to be placed in the opposite scale. The principles of the system ought to be applicable in every instance. The phrenologists, however, aware of numerous and striking exceptions, elude their evidence by asserting, that when a certain portion of the cranium and of the brain is greatly developed, while the faculty there lodged has never been remarkably distinguished, it nevertheless existed naturally, though the innate talent, for want of proper cultivation, has never been displayed; the predominant organic power was never discovered by the owner, though, according to the principles of the doctrine, with this organic power a proportional impulse to exertion, or an instinctive energy is combined, which communicates of itself a strong and irresistible tendency to particular pursuits. When, again, a strongly marked propensity, or a decided talent has been manifested without any corresponding amplitude of structure, it is in like manner pleaded, that by sedulous exercise and culture, a natural deficiency has been overcome. Thus the phrenologist avails himself of a double method of elusion; his position, like the cave of Philoctetes, affords him an escape on either side; and in one direction or another he contrives to baffle all the address of his opponents.

"If, however, the testimony of facts in a great scale should be found adverse to the alleged coincidences, or to the correspondence of given mental equalities with certain conditions of the brain, phrenology will not continue to make proselytes, and it will be ultimately discarded as an hypothesis without foundation. At present, most inquisitive persons seem to be in doubt on this subject, and to be looking out for evidence. I have taken every opportunity that has occurred to me for many years of making inquiries of persons who had a great field of observation within their reach, what had been the result of their experience on this subject. Many of the persons have been physicians, who were superintendants of extensive lunatic establishments. Some of them had been men who had addicted themselves to the study of phrenology, and were predisposed to imbibe the opinions of its authors; some have been persons distinguished by their researches in the anatomy and physiology of the brain and nervous system. Among these I do not remember to have found one who could say that his own observation had afforded any evidence favourable to the doctrine. Yet we should imagine, that a man who lives amidst hundreds of monomaniacs must have constantly before his eyes facts so obvious that he could not be mistaken in their bearing. Some hundreds, and even thousands of such persons have passed a part of their lives under the inspection of M. Esquirol, who possesses most extensive resources for elucidating almost every subject connected with the history of mental diseases, and has neglected no inquiry which could further the attainment of that object. The result of his observations will be allowed to be of some weight on the decision of this question, in which the appeal is principally to facts of the precise description of those with which he has been chiefly conversant. At his establishment at Ivry he has a large assemblage of crania and casts from the heads of lunatics, collected by him during the long course of his attendance at the Salpêtrière, and at the Royal Hospital at Charenton, which is under his superintendance. While inspecting this collection, I was assured by M. Esquirol, that the testimony of his experience is entirely adverse to the doctrine of the phrenologists; it has convinced him that there is no foundation whatever in facts for the system of correspondences which they lay down between given measurements of the head and the existence of particular mental endowments. This observation of M. Esquirol was made in the presence of M. Mitivié, physician to the Salpêtrière, and received his assent and confirmation. M. Foville, physician to the extensive lunatic asylum at St. Yon, gave me a similar assurance. There are few individuals in Europe whose sphere of observation has been so extensive as that of M. Esquirol and M. Foville, and certainly there are none whose science and habits of observation better qualify them to be witnesses in such a subject of inquiry; but testimonies to the same result may be collected from unbiassed witnesses, whose evidence taken collectively may have nearly equal weight. Among these there are men unscientific, though capable of correct and unprejudiced observation, as well as anatomists and physiologists. In the number of the latter is Rudolphi, who declares that he has examined many hundreds of brains without finding any thing that appeared to him favourable to the phrenological theory."[2]

Evaded by the phrenologists.

The mode in which Dr. Combe evades the force of the strong testimony here adduced, is quite characteristic of the disposition to be found amongst confirmed phrenologists, of resolutely rejecting all evidence that militates against the system they have adopted. Thus, he says, in reference to the passage we have just quoted, "If Dr. Prichard believes that the intelligent and benevolent Esquirol, is that person," (namely, one "competent to form a judgment on the subject,") and if his collection of crania and casts be the hostile evidence which is relied on, this only proves, in a forcible manner, that Dr. Prichard is himself not competent to judge, or that he has not taken time either to examine the collection of crania, or to ascertain the competency of Esquirol and Metivié, to decide on the merits of the question on which they volunteered an opinion."[1] We cannot help remarking here, that, on another occasion, when criticising the suggestion we threw out, in the Essay on Cranioscopy, of the propriety of inquiring into the talents and qualifications of observers before admitting the truth of the facts received on their testimony, a very different language was held. "When they" (the advocates of phrenology) "affirm that the subjects of observation are patent to the whole world, who have eyes to see, and understandings to comprehend; and when they say, compare manifestations with cerebral developement, and you are at the bottom of the problem yourself; what need for inquiry into their talents and qualifications to observe?" "When Gay Lussac hears that Sir Humphry Davy has made a discovery in chemistry, and reads Sir Humphry's statement of the way in which it was made, does he begin by inquiring first, whether it be possible to make the discovery at all, seeing natural substances are 'so changed and modified, exalted and subdued' by a multitude of powerful causes? And, after settling this point, does he, in the second place, proceed to inquire into Sir Humphry Davy's talents and qualifications as a chemist, and into his capacity to make the discovery, and then believe it, or not, according to the result of this investigation? No man who knows the first rudiments of philosophy would follow so absurd and preposterous a course. What should we think of Gay Lussac's refutation of Sir Humphry's discovery, founded on a metaphysical inquiry into the possibility of making it, and into the 'talents and qualifications' of the discoverer? We should pity him for his ignorance of the rudiments of philosophy."[2]

[1] *Life of Sir Walter Scott*, by Lockhart, vol. vii. p. 395, note.

[2] *Treatise on Insanity*, pp. 476, 477.

This happy talent, possessed by the champions of phrenology, of shaping their course either one way or the opposite, according as it may suit the convenience of the occasion, enables them, at one time, to proclaim, that the evidences of their science are palpable and demonstrative, that the field of nature is open to all inquirers, that "every one who has eyes may see" and judge for himself; and at another, when such judgment is against them, they can turn round, and allege that in order to arrive at the truth a peculiar discretion and tact, acquired by long experience and careful appreciation of minute and hair-breadth differences of size is necessary. They can then declare that the observer who has not arrived at the same conclusions as themselves, is doubtless incompetent to the task he has attempted; and that his testimony, being of no value, ought to be wholly set aside.

Process of verification.

Let it be borne in mind, then, by the practical inquirer into the truth of phrenology, that he will not be esteemed qualified to verify its doctrines, unless he be previously deeply versed in the new system of psychology, can assign to each of the thirty-five special and primary faculties of the soul its sphere of operation, and has acquired a readiness in unravelling their multifarious combinations, so as to analyze, by this subtile metaphysical chemistry, all human qualities into their proximate and ultimate elements, refer all actions to their proper innate impulses, and assign the proportions of the various ingredients which are mixed up in the formation of the character of each individual. No one is competent to excel in this new branch of philosophy who doubts the possibility of appreciating the intensities of moral or intellectual qualities by geometrical measurements, on scales divided into tenths and hundredths of inches. The young and ardent phrenologist, who after having applied his callipers to the skull subjected to his examination, and taken a note of the dimensions of each of the thirty-five organs, proceeds to verify his observations by comparing them with the character of the possessor of those organs, will never fail to meet with *wonderful coincidences*, sufficient to give him the greatest satisfaction, and confirm him in the persuasion that he possesses the real key to the secrets of nature in the hitherto recondite science of mental philosophy. A moderate share of dexterity in reconciling apparent discrepancies will suffice to ensure a preponderance of favourable evidence; since, fortunately, there have been provided in the brain different organs, sometimes of similar and sometimes of opposite properties, capable, by a little adjustment of *plus* or *minus* on either side of the equation, of furnishing the requisite degrees of the mental quality sought for, and of thus solving every psychological problem. We shall suppose, for instance, that he is inspecting the head of a person known to have given credit to the prophecies of a weather almanack; he finds, on reference to the "system of phrenology," that a belief in astrology is the offspring of No. 16, that is, *ideality;* so that if this organ happen to be sufficiently large, the phenomenon is at once accounted for. But if it be not, our phrenologist will have another chance; for he will probably discover it to arise from the dimensions of No. 15, which inspires *hope*, the source of the *propensity to credulity*. Habitual *irresolution* may result either from the magnitude of No. 12, or the diminutiveness of No. 18; thus affording very great convenience for making our observations of the character square with those of the dimensions of the organs, and *vice versa*. If, again, the magnitude of the organ of *combativeness* accord with the manifestations of pugnacity given by the individual, it is well, and we need inquire no farther, but set it down at once as an irrefragable proof of the accuracy of phrenological determinations. Should the correspondence, however, not prove satisfactory, the organ being large for instance, and the manifestation small, we have then further to examine the dimensions of the organ of *caution*, the influence of which is to moderate and check the operation of the former; and we shall perhaps find this organ sufficiently large to account for the phenomenon. Both these organs may be large, or both small, or the first may be small and the second large, or the converse; and other modifications of action may result if either one or both be only of moderate size, allowing great latitude of choice in the assignment of motives. Should we be so unfortunate as to exhaust all the combinations without meeting with the success we desire, there is still an abundance of auxiliary faculties of which we may avail ourselves with advantage. If we were to explain the fact of the individual in question having accepted a challenge, he might have been inspired by *combativeness*, whose voice was "still for war," or goaded on by *destructiveness*, to fight that he might destroy; *firmness* may have urged him to persevere by the consideration that he had previously resolved it, and *concentrativeness*, by rivetting his attention to the subject, may have screwed his courage to the sticking place; or he may have been prompted by *imitation* to follow the example, or by *approbation* to gain the applause of his friends. We have also to take into the account the countervailing influence of faculties which are pulling in the opposite direction, and qualifying the combined powers of the former incentives: And should *cautiousness* not be in sufficient force, we are to consider the power of *conscientiousness*, which preaches forbearance, meekness, and forgiveness; of *veneration* which appeals to the high authority of religion and of law; of *benevolence* restraining the hand from inflicting pain and death; of *approbation*, who qualifies her sanction by raising other voices condemnatory of the deed; and last, though not least, the *love of life* which recoils with instinctive dread from the possible catastrophe. Drawing, then, a diagram of all these component moral forces, in their proper directions, and suitable proportions, it will not be very difficult to obtain by this artificial dynamico-phrenological process, the exact resultant which corresponds with the actual fact to be explained.

---

[1] *Phrenological Journal*, viii. p. 654.

[2] *Essays on Phrenology*, p. 71.

Lest it should be imagined that the above description is a caricature of the new method of philosophizing, so admirably calculated to establish the truths of phrenology, we shall beg to quote the following passage from Sir George Mackenzie's *Illustrations* as an example of this satisfactory process of ratiocination.

"In discussing the conjectured faculty of inhabitiveness with Mr. Combe, he had the goodness to make us acquainted with a case, in which *locality* and *inhabitiveness* were both very moderate in developement, but the *propensity to wander*, as he informed us, very powerful. Dr. Spurzheim mentions this propensity as belonging to *locality*, and he states several remarkable cases in which the organ was much developed, and the propensity strong. The case referred to by Mr. Combe was, on this account, interesting; and we will state the result of our inquiries into the particulars, for the purpose of giving an example of the caution with which we ought to receive the description of any case brought in opposition, since it sometimes appears to be necessary even among friends.

"The young man to whose case we refer, had a very strong desire to adopt a seafaring life, contrary to the wishes of his friends. It occurred to them, that a voyage up the Baltic, during the stormy months of October and November, might have the effect of giving him a disgust to the profession for which he showed so ardent a desire. He suffered so many privations and hardships, that he yielded to the wishes of his friends, although the desire to go to sea continued as strong as ever. On proposing a few questions, we found that the propensity was confined to *being at sea;* that this propensity did not originate in a desire to wander; for neither travelling on land, nor mere change of place, would have gratified the propensity. At the same time, the person referred to declared, that regular voyages to the same place would not have satisfied him. The propensity had haunted him as long as he could remember any thing. Being anxious himself to contribute to the unravelling of what appeared mysterious and irreconcilable to the system, he stated that he used to go once or twice a-day to examine the mechanism and rigging of ships in Leith harbour, an employment of which he was passionately fond; and long before he commenced his trial voyage, he had become familiar with the names and uses of every part of a ship, and of the rigging. He was fond of machinery, and has often amused himself by making models of ships; and his mechanical turn was so strong, that he had constructed a model of machinery, by which a ship's motion may be applied to work the pumps. This mechanical propensity, and his early attachment to naval machines, together with *firmness*, appear to us to have given rise to his desire for a sea-faring life. *Courage* might also have prompted his wish to enter the navy. Thus the supposed propensity to wander appeared not to exist; and it was found that a mechanical genius, an early attachment[1] to the mechanism of a ship, *perseverance, courage*, and probably also love of *approbation*, or ambition, and *ideality*, all of which were well developed in the individual referred to, combined to inspire the desire to enter the navy." *(Illustrations of Phrenology*, p. 170.)

It is to be lamented that, at the period when this elaborate investigation was undertaken, the organ of *wonder* had not yet been made; for as one of the functions of this organ, according to Mr. Combe, is to "incite young men to chuse the sea as a profession," much light would have been thrown upon the object of the inquiry by a critical examination of its dimensions compared with those of all the other organs which were taken into consideration as combining their influence in producing the result.

There is this very remarkable peculiarity in the pursuit of phrenology, that the student is perplexed, not with the difficulties, but with the facilities it affords for explaining every phenomenon. The pliability of its doctrines is exemplified, not merely in the analysis of motives, but likewise in the influence which we are allowed to ascribe to the habitual exercise, or education of the faculties. The observed magnitudes of the respective organs indicate, not the acquired, but the natural powers, sentiments, and propensities. Now, the character of the individual is the joint result of the force of natural endowments, and of the amount of moral and intellectual cultivation which has been bestowed upon them. But can we ever know enough of the minute history of the progress of the mind of any individual to enable us to form a correct estimate of the relative power of these two elements, which have, in the formation of each respective faculty, combined their operations? If it be true that an organ may be the seat of a faculty varying in its activity according to the occasions which call it forth, by what physical criterion can we distinguish the active from the dormant conditions of that organ? Unless we can draw, with precision, these distinctions, it is evident that the ground of all cranioscopical observation is cut from under us.

It may be indeed alleged, that at all periods of life, and even after the bones of the skull are consolidated, the organs increase or diminish in size according to the exercise or disuse of the faculty associated with it, whether such change may have been brought about by voluntary training, or by the discipline of circumstances; and certainly, if such were the fact, our experience would repose on a much surer basis, than if the form of the organs merely retained the stamp originally impressed upon them by nature. But the hypothesis that the cerebral organs acquire additional size by the exercise of their powers was positively rejected as untenable by Dr. Spurzheim, as we have heard him publicly declare; and it is, we believe, repudiated by the generality of phrenologists.

Progress of phrenology accounted for.

We do not think it difficult to account for the progress which phrenology has made amongst the very numerous class of persons who find in it a source of agreeable occupation, giving exercise to their ingenuity in discovering striking coincidences, and gratifying their self-complacency by inspiring them with the fancy that they are penetrating far into the mystic regions of psychology. For the last twenty or thirty years, various popular writers, and lecturers without number, have been displaying their powers of elocution, exercising their skill in the critical examination of developements, and expounding the doctrines of the new philosophy to wondering and admiring audiences. With all these advantages and appliances to boot, the wonder seems to be, not that phrenology has met with the success of which so much boast is made, but that it has not speedily gained the universal assent; for had it been a real science, like that of Chemistry and other branches of Natural Philosophy, founded on uniform and unquestionable evidence, it could not have failed, by this time, of being generally recognised as true.

When we consider that the present age is not one in which there is any lack of credulity, or in which a doctrine is likely to be repudiated on the score of its novelty or its extravagance, we cannot but smile at the complaints of persecution uttered by the votaries of the system of Dr. Gall, and at the attempts they make to set up a parallel between its reception in this country, in these times, and that which, two centuries ago, attended the speculations of Galileo, and subjected him to the tyrannous cognisance of the Inquisition; or to establish an analogy between the dogmas of phrenology and the discoveries of the circulation of the blood, and of the analysis of light, which have immortalized the names of Harvey and of Newton.

(Y.)

---

[1] "Dr. Spurzheim has shown, that the faculty of attachment extends its influence to inanimate things, as well as to animate beings."

Phrygia.

PHRYGIA, a country in Asia. The origin of the name is uncertain; but some say that it was derived from the river Phryx, now Sarabat, which divides Phrygia from Caria, and empties itself into the Hermus; whilst others think that it was so called from Phrygia, the daughter of Asopus and Europa. The Greek writers inform us that the country took its name from the inhabitants, and these from the town of Brygium in Macedonia, whence they first passed into Asia, and gave the name of *Brygia* or *Phrygia* to the country where they settled. Bochart is of opinion that this tract was called Phrygia from the Greek verb φρυγειν, *to burn* or *parch*, which, according to him, is a translation of its Hebrew name, derived from a verb of the same signification.

Nor are the opinions of authors less various as to the ancient boundaries of this country; an uncertainty which gave rise to an observation of Strabo, that the Phrygians and Mysians had distinct boundaries, but that it was scarcely possible to ascertain them. The same writer adds, that the Trojans, Mysians, and Lydians, are, by the poets, all blended under the common name of Phrygians, which Claudian extends to the Pisidians, Bithynians, and Ionians. Phrygia proper was, according to Ptolemy, bounded on the north by Pontus and Bithynia; on the west by Mysia, Troas, the Ægean Sea, Lydia, Mæonia, and Caria; on the south by Lycia; and on the east by Pamphylia and Galatia. It lies between the 37th and 41st degrees of north latitude, and extends in longitude from 56 to 62 degrees. The inhabitants of this country, mentioned by Ptolemy, are the Lycaones and Anthemisenii towards Lycia, and Moccadelis or Moccadine; the Cyddeses or Cydisses towards Bithynia; and the Peltini or Speltini, the Moxiani, Phylacenses, and Hierapolitæ, between these. To the latter may be added the Berecyntes, mentioned by Strabo.

Phrygia is commonly divided into the Greater and Lesser, called also Troas. But this division did not take place till Troas had been subdued by the Phrygians; and hence it is rather considered by some Roman writers as a part of Phrygia, than Bithynia, Cappadocia, or any other of the adjacent provinces. In after ages the Greater Phrygia was divided into two districts or governments; one called Phrygia Pacatiana, from Pacatianus, who, under Constantine, was the *præfectus prætorio* of the East; and the other Phrygia Salutaris, from some miraculous cures supposed to have been performed there by the archangel Michael.

This country, and indeed all Asia Minor, was in ancient times greatly celebrated for its fertility. It abounded in all sorts of grain, being, for the most part, a champaign country covered with a deep and rich soil, and plentifully watered by small rivers. In some parts it produced bitumen and other combustible substances. The plains were also well stocked with cattle and pasture grounds. The air was anciently deemed pure and wholesome, although it is now in some parts thought extremely bad, great part of the country lying uncultivated.

Phrygia Major anciently contained several cities of great celebrity, such as Apamea, Laodicea, Hierapolis, Gordium, &c. There were also in it some famous rivers, such as the Marsyas, the Mæander, &c. The Mæander is now named Madre or Mindre, and was much celebrated by the ancients for its windings and turnings; whence all such windings and turnings have been denominated meanders.

The Phrygians accounted themselves the most ancient people in the world. Their origin, however, is extremely uncertain. Josephus and St Jerome say that they were descended from Togarmah, one of Gomer's sons; and that they were known to the Hebrews under the name of Tigrammanes. The heathen authors derive them from the Brygians, a people of Macedonia. But this is a mere conjecture, being totally unsupported, except by the similarity of names. Bochart thinks that the Phrygians were the offspring of Gomer the eldest son of Japhet, the word Phrygia being the Greek translation of his name. Josephus makes Gomer the father of the Galatians; but by the Galatians he must necessarily mean the Phrygians inhabiting that part of Phrygia which the Galatians had made themselves masters of; the descendants of Gomer having been placed by Ezekiel to the northward of Judæa, near Togarmah (which Bochart takes to be Cappadocia), long before the Gauls passed over into Asia. We are willing to let Gomer enjoy the fine country which Bochart has been pleased to assign him, and concede to him the honour of being the progenitor of the Phrygians, since we know no other person upon whom it can be conferred with any degree of probability.

The ancient Phrygians are described as superstitious, voluptuous, and effeminate, without any prudence or foresight, and of such a servile temper that nothing but stripes and ill usage could make them perform their duty; a character which gave rise to several trite and well-known proverbs. They are also said to have been the inventors of divination by the singing, flying, and feeding of birds. Their music, commonly called the *Phrygian mood*, is alleged by some as a proof of their effeminacy.

The government of this country was certainly monarchical; for during the reigns of some kings, Phrygia was subject to one prince. Ninnacus, Midas, Manis, Gordius and his descendants, were undoubtedly sovereigns of all Phrygia. But some time before the Trojan war we find this country divided into several petty kingdoms, and different princes reigning at the same time. Apollodorus mentions a king of Phrygia as contemporary with Ilus king of Troy. Cedrenus and others speak of one Teuthrans, a king of a small country in Phrygia, whose territories were ravaged by Ajax, whilst he himself was slain in single combat, his royal seat laid in ashes, and his daughter, named Tecmessa, carried away captive by the conqueror. Homer makes mention of Phorcys and Ascanius, both princes and leaders of the Phrygian auxiliaries who came to the relief of Troy. Tantalus, a prince no less famous for his great wealth, than infamous for his covetousness and other detestable vices, was only king of Sipylus and its adjacent district. That Phrygia was subdued either by Ninus, as Diodorus Siculus informs us, or by the Amazons, as we read in Suidas, is not sufficiently established. Most authors who speak of Gordius tell us, that the Phrygians, having sent to consult an oracle in order to learn how they might put an end to the intestine broils which divided their country into many factions and parties, received for answer, that the most effectual means to deliver themselves and their country from the calamities under which they groaned, was to commit the government to a king; an advice which they followed accordingly, and placed Gordius on the throne.

Apamea was the chief emporium of all Asia Minor. Thither resorted merchants and traders from all parts of Greece, Italy, and the neighbouring islands. Besides, we know from Syncellus, that the Phrygians were for some time masters of the sea; and none but trading nations ever prevailed on that element. The country produced many choice and useful commodities, which afforded considerable exports. They had a safe coast, convenient harbours, and whatever may incline us to think that they carried on a considerable trade. But as most of the Phrygian records are lost, we will not dwell on conjectures so difficult to be ascertained.

We have no remains of the Phrygian laws; and in regard to their learning, as we are informed that for some time they enjoyed the sovereignty of the sea, we may at least allow them a competent skill in geography, geometry, and astronomy, besides their reputed knowledge of music. Some have been of opinion that the Phrygian language bore a great resemblance to the Greek; but the contrary is manifest from the few Phrygian words which have been transmitted to us, and carefully collected by Bochart and Rudbechius. To these we may add the authority of Strabo, who, after attempting to derive the name of a Phrygian city from the Greek, concludes that it is a difficult matter to discover any similitude between the barbarous words of the Phrygian language and the Greek. The Phrygian tongue, after the experiment made by Psammetichus, king of Egypt, was looked upon by the Egyptians as the most ancient language of the world. But other nations, particularly the Scythians, refused to submit to their opinion, as founded on an argument of no real weight. "As the two children," say they, "had never heard the voice of any human creature, the word *bec*, or *bekkos*, the first they uttered, was only an imitation of the goats that had suckled them, and happened to be a Phrygian word signifying *bread*."

As the Phrygians were superstitious, their idols were consequently numerous. The chief of these was Cybele, who went by a variety of names. They also worshipped Bacchus under the name of Sabazios, and called his priests Saboi.

The history of their kings is dark and uncertain, and the dates of their several reigns and actions cannot now be fixed. We refer such of our readers, therefore, as wish to know what is certain respecting them, to the Ancient Universal History.

PHRYGIANS, a Christian sect. See CATAPHRYGIANS and MONTANISTS.

PHRYNE was a celebrated courtezan, who flourished at Athens about 328 years before the Christian era. She was mistress to Praxiteles, who drew her picture, which was one of his best pieces, and placed in the temple of Apollo at Delphi. We are told that Apelles painted his Venus Anadyomene after he had seen Phryne on the sea-shore naked, and with dishevelled hair. Phryne became so very rich by the liberality of her lovers, that she offered to rebuild, at her own expense, Thebes, which Alexander had destroyed, provided this inscription were placed on the walls, *Alexander diruit, sed meretrix Phryne refecit;* but her offer was rejected.

PHRYNICHUS, a tragic poet of Athens, was the son of Polyphradmon or Phradmon, and the disciple of the celebrated Thespis, being a little earlier than Æschylus. He gained the tragic prize, B. C. 511, and is said to have introduced several improvements into the dramatic art, bringing on the stage female characters, and making the actors adopt the use of masks instead of disfiguring their faces with the lees of wine. Suidas mentions the names of nine of his tragedies, and ascribes to another Phrynichus, son of Melanthes, a tragedy entitled *The Sack of Miletus*, which recalled so forcibly to the Athenians the melancholy fate of that Greek city, that they punished the poet by a fine of a thousand Attic drachmæ, or, according to Ælian, banished him from Athens. As the son of Phradmon is said to have died in Sicily, probably at the court of Hiero, where Æschylus also took refuge, it is not unlikely that this tragedy may have been his production.

PHRYNICHUS, one of the last writers of the old comedy at Athens, flourished B. C. 435, and was the contemporary of Eupolis, Euripides, and Aristophanes. He obtained the second prize, B. C. 405, the year before Athens was taken by the Spartans. Plutarch states, that in one of his plays he defended Alcibiades when he was accused of having mutilated the statues of Hermes. Aristophanes ridicules Phrynichus for introducing too frequently on the stage characters in low life. The fragments of Phrynichus have been collected by Morel, *Ex Veterum Comicorum Fabulis quæ integra non extant*, Par. 1553; by Hertelius, *Vetustissimorum Comicorum Sententiæ*, Bâle, 1560; and by Grotius, *Excerpta ex Tragœdiis et Comœdiis, Gr. Lat.* Par. 1626.

PHRYNICHUS ARRHABIUS, a Greek grammarian, was a native of Bithynia, and flourished about the middle of the second century, in the reigns of Marcus Aurelius and of Commodus. He had devoted much time to the study of the Greek language, which he pretended to speak and write in the utmost purity. He made a collection of all the words used in the Attic dialect, of which an abridgment has been preserved under the title *Eclogæ Nominum et Verborum Atticorum.* He rejected every word which could not be found in some work of Plato, Thucydides, or Demosthenes, and was particularly severe on the style of Menander. This little work, published first by Calliergi, Rome, 1517, was reprinted at Venice, 1524; but the best edition is that of C. A. Lobeck, with learned annotations, Leipzig, 1820, 8vo. Phrynichus had also collected examples of every different kind of style, in the form of a dictionary, divided into thirty-five books, which he dedicated to the Emperor Commodus. This compilation, entitled *Apparatus Rhetoricus sive Sophisticus*, was still extant in the time of Photius. Some fragments remain, which have been published by Montfaucon in the *Bibliotheca Coisliniana*, p. 465–69.

PHRYXUS, in fabulous history, was a son of Athamas, king of Thebes, by Nephele. When his mother was repudiated, he was persecuted with the most inveterate fury by his stepmother Ino, because he was to sit on the throne of Athamas, in preference to the children of a second wife. His mother, or, according to others, his preceptor, apprised him of Ino's intentions upon his life; and, the better to make his escape, he secured part of his father's treasures, and privately left Bœotia with his sister Helle, to proceed to the court of Æetes, king of Colchis. They embarked on board a ship, or, as we are informed by the poets and mythologists, they mounted on the back of a ram, whose fleece was of gold, and proceeded on their journey through the air. The height to which they were carried rendered Helle giddy, and she fell into the sea. Phryxus gave his sister a decent burial on the sea-shore, and after he had called the place *Hellespont*, from her name, he continued his flight, and arrived safely in the kingdom of Æetes, where he offered the ram on the altar of Mars. The king received him with great tenderness, and gave him in marriage Chalciope, his daughter, by whom he had Phrontis Melas and Argos Cylindrus, whom some call Cytorus. He was afterwards murdered by his father-in-law, who envied him the possession of the golden fleece; and Chalciope, to prevent her children from sharing their father's fate, sent them privately from Colchis to Bœotia, the jealousy or resentment of Ino, who was then dead, being no longer to be dreaded. The fable of the flight of Phryxus to Colchis on a ram has been explained by some, who observe, that the ship in which he embarked was either called by that name, or carried on her prow a figure of that animal. The fleece of gold is accounted for by observing that Phryxus carried away immense treasures from Thebes. Phryxus was placed after death amongst the constellations of heaven. The ram which carried him to Asia is said to have been the fruit of Neptune's amour with Theophane the daughter of Altis. This ram the gods had given to Athamas to reward his piety and religious life; and Nephele procured it for her children, just as they were going to be sacrificed to the jealousy of Ino. The murder of Phryxus was some time afterwards amply revenged by the Greeks, having occasioned the famous expedition under Jason and many of the princes of Greece, which had for its object the recovery of the golden fleece, and the punishment of the king of Colchis for his cruelty to the son of Athamas.

PHUGWANA, a large walled town of Hindustan, in the province of Lahore, belonging to the Sikhs. It is situated between the Beyah and the Sutelege Rivers, south-east from Jallinder, in a fertile and well-cultivated plain, which produces wheat and other grains, and also the sugar-cane.

PHYLACTERY, in general, was a name given by the ancients to all kinds of charms, spells, or characters, which

Phylactery
||
Physic.

they wore as amulets, to preserve them from danger or disease.

Phylactery particularly denoted a slip of parchment, on which was written some text of Scripture, generally of the decalogue, which the more devout people amongst the Jews wore on the forehead, the breast, or the neck, as a mark of their religion. The primitive Christians also gave the name of *phylacteries* to the cases in which they enclosed the relics of their dead. Phylacteries are often mentioned in the New Testament, and appear to have been very common amongst the Pharisees in our Lord's time.

PHYLLIS, in fabulous history, was a daughter of Sithon, or, according to others, of Lycurgus, king of Thrace, by whom Demophoon, the son of Theseus, at his return from the Trojan war, was received and hospitably entertained. Phyllis became enamoured of him, and did not find him insensible to her passion. After some months of mutual tenderness and affection, Demophoon sailed for Athens, whither his domestic affairs recalled him. He promised faithfully to return before a month had expired; but either a dislike for Phyllis, or the irreparable situation of his affairs, obliged him to violate his engagement; and the queen, growing desperate on account of his absence, hanged herself, or, according to others, threw herself from a precipice into the sea and perished. Her friends raised a tomb over her body, where there sprung up certain trees, the leaves of which at a particular season of the year suddenly became wet, as if shedding tears for the death of Phyllis. According to an old tradition mentioned by Servius, Phyllis was changed by the gods into an almond-tree. Some days after this metamorphosis, Demophoon revisited Thrace; and when he learned the fate of Phyllis, he ran and clasped the tree, which suddenly shot forth, and blossomed, as if still sensible of tenderness and love.

PHYSHARMONICA, a musical instrument, in which the immediate sonorous bodies are springs of steel or of brass, thrown into vibration by a current of air impelled against them. It was invented by Hackel, at Vienna, and is an instrument of the same kind as the æolodicon, or æoline, which was previously invented by Eschenbach, a Bavarian. The same sort of instrument was reproduced in England a few years ago. On the Continent it has been introduced into organs as a very efficient stop. See the article Music for some notices of similar instruments.

PHYSIC, PRACTICE OF.

We feel that it would be unsuitable to occupy the pages of a work like this with an epitome of the Practice of Physic, composed either on such a scientific plan as would adapt it to members of the medical profession, or in such a more popular style as would be requisite were it addressed to general readers. But there are some topics connected with the study and exercise of the medical profession, from a discussion of which general readers may derive, we conceive, both interesting and useful information. In particular, it seems extremely desirable that the public should entertain more accurate notions than generally prevail, as to the nature and extent of the *difficulties* medical men have to encounter in the exercise of their profession;—difficulties that are in part, no doubt, common to medicine with all other practical sciences; but which must also be attributed in a great measure to the peculiar character of the subject itself. By being better informed with regard to the nature and sources of these difficulties, the public would be better able to judge of the qualifications they ought to look for in those to whom they intrust their health; more reasonable in the expectations they form of the benefits to be derived from medical assistance; and less easily estranged than they are too apt to be, from a just reliance on persons of judgment and skill, by the boastful pretensions of ignorant and possibly uneducated empirics.

When the physician is called to a patient, there are two objects to which his attention is successively directed; *first*, to ascertain with what disease his patient is affected; and, *second*, to determine the method of treatment best suited for its cure or alleviation. In the following article we purpose to consider what are the means that the practitioner employs for effecting the first of these objects—for determining in practice what the disease is with which he has to contend; and, in particular, to take a general view of the difficulties he has to encounter in endeavouring to arrive at a correct judgment on this subject.

A knowledge of the disease with which his patient is affected, the medical practitioner can hope to attain only by an accurate observation of the morbid phenomena or symptoms that manifest themselves, combined with or followed up by a careful consideration of the pathological conditions from which his own experience and that of others has shown that the particular group of symptoms under his observation, or a group closely resembling it, may possibly originate. We had occasion in the article Medicine, in adverting to the attempts which have recently been made to undervalue the study of symptoms as compared with that of proximate causes, to point out the necessary connections and dependencies of these two subjects of medical inquiry; and to show that as, on the one hand, a more accurate observation of symptoms leads to greater precision in establishing the proximate causes of diseases, so, on the other hand, a more correct acquaintance with proximate causes leads to the more accurate noting and the more due appreciation of symptoms. But in considering the relations of symptoms and proximate causes, it is necessary to keep in remembrance, that there is a wide diversity in the degree of directness with which different symptoms indicate the morbid condition upon which they ultimately depend. Thus, if the lining membrane of the air-passages be inflamed, or, in other words, if a person be affected with catarrh, or bronchial inflammation, amongst the principal symptoms that will arise will be fever, cough, and expectoration. Now the *fever* is immediately an affection of the nervous and circulatory systems, liable to occur in a great variety of diseases besides bronchial inflammation. Its occurrence, therefore, warns us of derangement in some part of the economy, but does not lead us to the respiratory organs as the primary seat of this derangement. The *cough* depends on a preternatural action of certain of the respiratory muscles, and is liable to be excited by a number of different causes capable of calling these muscles into play. It serves in some degree, therefore, to guide us to the primary seat of disease. The altered secretion, again, of which the *expectoration* consists, is the immediate result of that state of inflammation of the lining membrane of the air-passages, which constitutes the proximate cause of the disease, and serves very materially to guide us to a knowledge both of its locality and of its nature.

In attempting to ascertain, from a consideration of the symptoms that present themselves, what the disease is with which his patient is affected, the conduct of the practitioner will vary according to the more or less inquisitive character of his mind. The empirical practitioner will content himself with endeavouring to determine what name the particular group of morbid phenomena or symptoms under his observation bears in systems of nosology; whilst the rational practitioner will aim at forming a judgment, from the consideration of these symptoms, as to the nature of the disease, or, in other words, as to the proximate cause on which it depends, and its immediate seat. Thus, if a patient presents the symptoms of yellowness of the skin and of the conjunctiva of the eye, the alvine evacuations being whitish or clay-coloured, and the urinary of a yellowish red or saffron hue, the empirical practitioner will be satisfied with knowing that he has to do with a case of jaundice, as distinguished from all other *nosological diseases;* whilst the rational practitioner or dogmatist will push his inquiries with the view of determining, if possible, whether the jaundice, in this particular case, is referrible to some morbid alteration of the structure of the liver itself, to the presence of gall-stones in the gall-ducts, or to the existence of spasm in these canals (morbid conditions or *pathological diseases* which may all separately or conjointly produce the symptoms that have been enumerated), or, in short, with the view of ascertaining what particular form of jaundice he has to subject to treatment. Both these practitioners must depend upon their observation of the symptoms that present themselves, for attaining the knowledge which they respectively desire. But the rational practitioner, whose object it is to arrive at a knowledge of the particular form of jaundice under consideration, must investigate these symptoms more accurately and minutely than is requisite for him who is content with the general knowledge of the fact, that the disease with which his patient is affected is that which has been termed jaundice. In the investigation of the rationalist, it is obvious, the differences between the objects to be distinguished, viz. the different forms of jaundice, are less apparent, the resemblances of these objects are closer, and their analogies are more striking, than those that exist between the objects of the empiric's comparison, viz. jaundice and other nosological diseases; and, consequently, a nicer and more elaborate analysis is required for their discrimination.

The process of analysis which the scientific medical practitioner has to carry on in his own mind, in endeavouring, from a consideration of the combinations of morbid phenomena or symptoms that present themselves to his observation, to arrive at a knowledge of the nosological disease with which his patient is affected, and of the morbid condition of the economy on which, in the particular instance, this nosological disease may depend, consists of several successive steps. 1*st,* He has to inquire what is the function, or what are the functions, a morbid affection or derangement of which is indicated by the symptoms observable. 2*d,* What is the particular process, or what are the particular processes, in the deranged function or functions, that are more immediately indicated as being disturbed. 3*d,* If several functions be deranged, he has to consider whether these derangements ought to be regarded as separate and independent occurrences, or as being dependent on one another; and if the latter, what is the particular relation subsisting between them in respect of antecedence and consequence. 4*th,* By these considerations respecting the deranged functions, the practitioner is gradually led to determine in his own mind what is the organ or part of an organ that is primarily and principally affected. And, 5*th,* having formed his judgment as to what is the organ, part of an organ, or texture affected, he has to consider the manner in which it is affected, or, in other words, what is the nature of its morbid condition; whether the symptoms can be supposed to depend on simple dynamical derangement, or whether they imply the existence of organic alteration of structure (see article PATHOLOGY); and also, what is the particular morbid change in property or in structure that must be supposed to exist. Under this last head is obviously comprehended the determination of the pathological nature of the disease with which the practitioner has to contend,—the consideration upon which the practice he is to pursue must necessarily be founded.

In each of the steps of this analytic process there is, in respect of a large number of diseases, ample room for mistake, not only in consequence of ignorance on the part of the practitioner, but in consequence also of the defective state of medical knowledge depending on the inherent difficulties of the subjects to which it relates. In whatever stage of the analytic process such mistakes may originate, their ultimate effect must be to lead the practitioner into one or other of two errors; 1*st,* that of supposing the existence of morbid conditions which do not actually exist; or, 2*d,* that of overlooking the presence of morbid conditions which do exist.

Sources of difficulty and fallacy in diagnosis.

We shall endeavour, in the following article, to point out, and to illustrate by particular examples, some of the circumstances under which the practitioner is liable to commit such mistakes; or, in other words, in which difficulties and fallacies in diagnosis are liable to arise. Our illustrations shall be drawn chiefly from the writings of some of the most eminent clinical physicians of the present day, in order to obviate any suspicion that the difficulties to which we refer are attributable to the want, on the part of the observer, of an acquaintance with those precepts which the present state of medical science furnishes for the discrimination of diseases from one another, or of skill in applying these precepts to particular examples. In the course of these illustrations it will appear, that not only may the several sources of difficulty and fallacy to be noticed exist separately, but that two or more of them may, in some instances, occur in combination, rendering the determination of the pathological condition or conditions existing in the economy a matter of proportionally greater difficulty.

I. Morbid lesions without symptoms.

The first circumstance to which we shall advert is the occasional existence of organic or structural pathological conditions in some of the textures, systems, or organs of the body, without this being indicated by any obvious or characteristic symptom, so that the physician remains entirely ignorant of their existence till it is revealed by examination after death.

Every part of the body, it may be presumed, is destined for the accomplishment of some particular end; and, reciprocally, each phenomenon which the economy exhibits is referrible to the operation of some particular part of the organized frame. It seems natural, therefore, to infer, that a deviation from the healthy structure of any part of the body must produce a determinate and perceptible change in the performance of the corresponding function; and, on the other hand, that where there occurs a deviation from the healthy performance of any of the functions of the economy, this must depend on some change having occurred in the structure of a corresponding part of the body;—in short, that where there is altered function, there must be corresponding alteration of structure; and where there is altered structure, there must be corresponding alteration of function. As general principles, these propositions are unquestionably true; but at the same time they are liable to very numerous and important exceptions. It has elsewhere been shown (PATHOLOGY, GENERAL) that very obvious deviations from the healthy exercise of the function of a part may manifest themselves during life, without its being possible to detect in that part, after death, the minutest deviation from its natural structure. And it is not less fully established, that in a large number of cases there have been found, on the dissection of bodies after death, deviations of parts from their healthy structure, of which no indicatory symptoms, direct or indirect, had presented themselves during life.

“ There is no anatomist,” as was remarked by Dr Thomas Simson, formerly the distinguished professor of medicine at St Andrews, “ who has had opportunity of opening any number of persons carried off without a manifest disease, but who must have had convincing proofs that there are great numbers of preternatural appearances in the body, which, during life, give no sensible disturbances.” (Edin. Med. Ess. and Observ. vol. v. p. 616.) “ It has been observed,” remarks another intelligent author (Dr Crampton, Trans. of the Assoc. Phys. in Ireland, vol. i. p. 1), “ by those physicians who are most in the habit of opening bodies, that they sometimes find morbid appearances after death, which they had not expected, even though they had closely attended to the antecedent symptoms.”

From the exercise of the function not being conspicuous.

From its purpose being unknown.

The circumstances upon which it may depend that a part of the body may be altered in its structure, and yet no deviation from its healthy functions, or from those of the economy generally, be observable, or at least be observed to result from this alteration, are very various. *First,* The exercise of the function of the particular organ may not be conspicuous to observation. *Secondly,* We may be ignorant of the purpose which the part serves in the economy, and consequently unable to detect any deviation from the proper exercise of its functions. It seems reasonable to expect that symptoms will be the more readily perceived, and the more characteristic when perceived, in proportion as we are well acquainted with the healthy functions of the organs on a morbid condition of which they depend, and can easily discern the exercise of these functions. And as the functions of those organs, and their several parts, are in general most apparent and best known, which either perform some of the vital motions (that is, of those motions without which life cannot be carried on for more than a very minute space of time), or which furnish some sensible secretions or excretions, so the symptoms resulting from diseased states of such organs must be more easy of detection, and more characteristic, than those symptoms that are connected with organs not similarly circumstanced. Thus, if the organs of respiration are out of order, or if the action of the heart, the spring of the circulation, is disturbed, the symptoms arising from such disorders are more readily perceived, and more easily referred to the organs concerned in their production, than are the symptoms that arise from the diseases of other parts the action of which is not so immediately necessary to life. If the secreting or excreting organs, as the liver or kidneys, fail in their proper offices, the symptoms thence arising are much more evident than those which depend on the derangement of organs that do not secrete any fluid from the blood; and among the organs that secrete a fluid, there will be greater facility in recognising the symptoms connected with those organs the fluid secreted by which is discharged out of the body, than with those organs whose fluid is retained in the body for the performance of some particular purpose; greater facility in recognising the symptoms produced by pathological conditions of the liver or of the kidneys, for example, than in recognising those produced by pathological conditions of the pancreas, though that, too, is a secreting organ, and separates from the blood a large quantity of fluid.[1] Dr Monro, in his enumeration of the circumstances which concur in rendering the history of diseases imperfect, has very properly included “ the imperfect knowledge we possess of the functions of some of the organs of the body. Thus,” adds he, “ we do not know whether or not the spleen be diseased, unless it has attained so great a bulk as to be felt by an external examination.” (Morbid Anatomy of the Gullet, &c. 1811, Introduction, p. xxx.) “ Nullum est viscus in corpore,” says Grottanelli, in a work expressly treating of diseases of the spleen (*Splenis Morbi,* p. 78, Florentiæ, 1821, 8vo), “ quod diutius subdole ægrotet, pathologicumque statum, absque manifesto detrimento servet, quam lien.”

From not be essent to life

Thirdly, The function of the organ may not be essential for the general wellbeing of the economy, as is the case with the ovary; or it may be of trivial importance in itself, and exercise little influence on the action of other organs, as is the case with the gall-bladder. “ Before there be any direct evidence of the existence of enlargement of the ovary, it has generally,” says Dr Hamilton, “ made a certain progress; and although there may be some data, from the appearances in dead bodies, for conjecturing the phenomena of the early stages of the disease, yet, practically speaking, a considerable advance must always have taken place before either the patient or the practitioner can be aware of its existence.” (Pract. Observat. on Subjects relating to Midwifery, part i. p. 71.) “ The gall-bladder,” says M. Andral, “ may be filled with calculi, and even with pus; its parietes may be the seat of different alterations; its cavity may have diminished in a considerable degree, or even disappeared; lastly, it may cease to receive bile, in consequence of the obliteration of the cystic duct, without there resulting during life, from any of these lesions, the production of any morbid phenomenon which can lead to a suspicion of their existence.” (*Clinique Médicale,* tome iv. p. 492.)

From contin notwit standin the org lesion.

Fourthly, The change which the organ has undergone, though apparently considerable in amount, may not be of a nature to prevent its performing its destined purposes in the economy. This seems in particular to be the case when the structural change occurs in a gradual manner, the parts apparently adapting themselves to their altered circumstances. “ When a compressing cause,” observes M. Cruveilhier, “ acts slowly on the brain, this organ accustoms itself to the compression, or rather the compressed portion becomes atrophied; and if this compressed or atrophied portion is not indispensable to the free exercise either of the sensory and locomotory functions, or of the intellectual faculties, the patient and the physician are not made aware, by any morbid feeling or phenomenon, of the existence of the cerebral lesion.” (*Anatomie Pathologique,* folio, livr. viii. pl. i. ii. and iii.) “ The very great frequency,” says Dr Sims, “ of collections of serous fluid found in the ventricles or membranes of the brain, in cases where no cerebral symptoms were known to have existed, is a subject of great importance to pathologists and practical physicians, especially when viewed in reference to the discrimination and curative treatment of apoplexy and other diseases of the nervous system. There is also a great variety of other morbid appearances found on dissection of the brain, in cases where no symptoms, or no symptoms adequate to explain the phenomena (that is, indicative of organic lesion of this organ), were noticed during life.”[2] “ Cerebral diseases,” says M. Rostan (Med. Clin. ii. 354), “ may go on without there existing any symptoms to characterize them. At all times the occurrence of latent diseases has been acknowledged; there exist fewer of them at present than formerly; our means of investigation have been multiplied to such a degree, that many diseases which would formerly have been overlooked, are in our days easily recognised. Nevertheless there are still affections of organs which we are surprised to meet with after death, and which have not produced during life any sign that could have revealed their existence. This point of pathology is truly very obscure, and almost inexplicable. It is very certain that these things happen when the affection has advanced slowly, and has destroyed the organ slowly; it is very certain also that a lesion of very limited extent, that has come on rapidly, gives rise to well-marked phenomena: but this does not alter the fact that, in the first case, an organ which is destroyed continues its functions; and that, in the second, an organ almost unchanged ceases from its functions. How can the functions still go on in the first case? how do they stop in the second? It is therefore very difficult, not to say impossible, to recognise diseases when they are truly latent; and that there are such, is proved by experience."

---

[1] See Introduction to A Treatise on Biliary Concretions, by Thomas Coe, M. D. 8vo. Lond. 1757.

[2] With the view of attempting to illustrate this subject, Dr Sims has subjoined a table, containing fifty cases of persons who died of various diseases not cerebral, and who manifested no symptoms referrible to the brain, though, on dissection, effusion of fluid and other morbid appearances were found in the brain or membranes. Med. Chir. Trans. xix. 274–5.

The secreting glands seem to be capable of undergoing a very great degree of organic change without their secretion being put a stop to, or even sensibly disturbed, so that unless some other symptoms should happen to indicate the affection that exists, it will not be manifested by any deficient exercise of the proper function of the organ. M. Chardel, in his valuable Monograph on Scirrhous Degenerations of the Stomach (Paris, 1808, p. 133), observes, "that the examination of a great number of dead bodies has convinced him, that frequently even the most considerable diseases of the liver occasion no impediment to the secretion of bile. Very large tumours may form in this organ, appearing to occupy the greatest part of its parenchyma, and still the secretion continue." And he particularly refers to a case of hydatid of monstrous size that had formed for itself a cavity in the liver, without the biliary secretion being put a stop to.

The urinary organs furnish us with numerous illustrations of the existence of organic affections, very considerable in their apparent degree, of which in many instances no indicatory symptoms manifest themselves during life, or at least during a considerable period of their existence. There is perhaps no organ of the body in which a greater extent of structural alteration may take place, without affecting, in a very marked degree, the exercise of its function, than the kidney. In some cases the urine has continued to be secreted when, from the progress of a particular form of disease, little more than the mere shells of the two kidneys has seemed to remain. (See Chardel, as above.) In other cases, calculi in considerable number, and of considerable dimensions, exist in the kidney without materially deranging their function, or otherwise betraying their own existence. "So long," says M. Chopart (*Malad. des Voies Urinaires*, i. 179), "as calculi remain concealed in the kidneys, they give no sensible signs of their presence. They may exist there and increase, without producing uneasiness, and without causing any symptoms that can even excite a suspicion of their existence. We have quoted examples of persons whose kidneys contained calculi which had not occasioned any pain to them. Baglivi found large calculi in the kidneys of two persons who, during life, had never complained in these viscera." To the same effect a more recent writer, Dr Marcet, in mentioning the symptoms with which calculus lodged in the kidney is generally accompanied, adds, "Yet cases of this kind occur in which these symptoms are scarcely perceptible; it will appear hardly credible, for instance, that the patient from whom the kidney represented in plate i. was taken, died of hydrothorax, at Guy's Hospital, without any symptom having occurred which could lead me to suppose that there was any disease in the urinary organs." (Essay on Calculous Disorders, 2d edit. p. 11.) In the case alluded to, the pelvis of the kidney was much enlarged and distended by a number of calculi closely pressed against each other; and other calculi were contained in the enlarged infundibula.

In the bladder, also, there may, under particular circumstances, exist disease to a considerable extent, without any indication of its existence being furnished by the attendant symptoms. "In several cases," says Sir Everard Home (Diseases of the Prostate Gland, ii. 239), "in which I have examined the body after death, calculi have been found enclosed in cysts formed between the fasciculi of the muscular coat of the bladder, so as to be entirely excluded from the general cavity, and therefore had not produced any of the common symptoms of stone. I have seen in the same bladder two, three, and even four such cysts, each containing a calculus of the size of a walnut." And, even independently of the existence of such cysts, calculi may, as Mr Wilson has remarked, "exist in the bladder for years, without producing always those distressing symptoms which render life a burden, and which so frequently occur in this disease." (Lectures on the Urinary Organs, &c. p. 238, 1821.)

From its being executed by another organ.

Fifth, Some other organ or part may supply the place of that which, by a change of structure, has, in whole or in part, been rendered incapable of exercising its function. This is especially the case with those glandular organs which are double; for when one of these is morbidly affected, the other not unfrequently performs its function in such a manner as to supply the place of both. "Suppression of urine," says Mr Howship (Complaints that affect the Secretion and Excretion of the Urine, p. 2), "may be complete or incomplete. The first case is very rare; the second comparatively frequent. An affection that either deranges or destroys the functions of one kidney, may leave the other to the more vigorous performance of its duty; a circumstance most happily calculated to guard the constitution from the ill effects of a disease the complete establishment of which is almost invariably fatal." "What we have said," remarks M. Bouillaud, "of the obscurity of the signs of diseases of the kidneys, is applicable to those of the lesions of the ureters. If these two canals were obliterated simultaneously, fatal consequences would ensue; but this does not happen when one of these organs only is obliterated. From a case which I shall relate, it appears that, in some instances of this kind, the kidney which has its ureter obliterated, has a tendency to become atrophied, whilst the other becomes hypertrophied, as if that it may be able of itself to fulfil the function which it formerly divided with that of the opposite side. I do not affirm, however, that this is in all instances the case." (*Journ. Compl.* xxxi. 15.)

May we, in this point of view, consider the brain or any portion of it as a double organ; that is to say, may we believe that the corresponding portions of its two hemispheres co-operate in the exercise of a common function, and that this function will continue to be performed without any sensible or considerable impairment, though the part concerned in its exercise is injured or diseased on one side, provided the corresponding part of the opposite hemisphere remains sound? M. Bouillaud (*Traité de l'Encephalite*, p. 263, 1825), in speaking of the lesions of the intellectual functions which occur in encephalitis, or inflammation of the brain, decidedly adopts this idea, "When one of the hemispheres only is diseased, either in whole or in part, the phenomena purely intellectual continue entire. I have adduced a great number of observations in support of this fact. The slightest reflection, indeed, might have enabled us to anticipate this result. It is obvious that the brain, the organ of the intellectual faculties, being composed of two halves, which are symmetrical and perfectly similar, each of them is equivalent, in what regards the mechanism of intelligence, to the two combined." And M. Lallemand had previously expressed his belief (*Rech. Anat. Pathol. sur l'Encephale*, 1820, i. 435), "that when the sound hemisphere of the brain is not compressed by the one which is diseased, it will continue to perform its functions in respect of intelligence, as in respect of voluntary motion and sensibility; that the patient will continue to think with a half of his brain, as he continues to see with one eye, and to hear with one ear."

Sometimes one organ may supply, in a mechanical manner, a deficiency or imperfection in its neighbour; and in such a case the existence of the deficiency or imperfection may not be indicated by any apparent disturbance of the action of the organ in which it exists. This happens by no means unfrequently, for example, when an aperture in the stomach, produced by chronic ulceration, is filled up by the adhesion of the liver, the pancreas, or the spleen, to the margins of the ulcer. "I have been often surprised," remarks Dr Pemberton (On the Abdominal Viscera, 3d edit. London, 1814, p. 130), "to find very extensive mischief in the structure of the stomach, without the constitution being sensibly affected by it; that is, provided the mischief was so situated as not to interrupt the passage of the food. I have seen a large scirrhus in the stomach, near the pylorus, with an open cancer in one part of it, which had made its way through the stomach and through the left lobe of the liver, and an adhesion had taken place between the sides of the abscess and the peritoneum; so that, had not the patient been taken off by a disease in the aorta, I have no doubt but that this abscess would have made its way out through the integuments of the abdomen. Still, however, though this must have been a disease of very long standing, the body was but little emaciated, and the patient had never shown any one symptom by which such a disease of the stomach could possibly have been suspected. This single case," adds Dr Pemberton, "is sufficient to point out the infinite difficulty there is to determine the nature of internal diseases."

From unknown reasons.

Sixth and *lastly*, Medical men must confess that, in some instances, they are unable to assign any plausible reason why the diseased organ does not reveal itself by any outward indication of deranged exercise of function. Thus M. Andral has related (*Malad. de l'Encephale*, p. 402, 403) some cases in which morbid softening of the brain, variable in its extent and in its seat, produced neither pain of the head nor disorder of the intellect, nor alteration of motion, nor disturbance of the sensations; nothing, in short, occurred during life that could even excite a suspicion of the central part of the nervous system being in any way affected. "As in these cases," remarks this accurate observer, "the softening was seated in different parts of the hemispheres of the brain, the absence of symptoms cannot be explained by the particular *seat* of the alteration. As to the *nature* of the alteration, it appeared identical in all the cases. In all, certainly, the softening was uncomplicated with any injection, effusion of blood, or other lesion; but its latency could not reasonably be attributed to this circumstance. Shall we explain it by *conditions inherent in the individuals themselves?* Shall we remark that they were all exhausted by chronic diseases, which must have blunted the sympathies, and diminished the tendency to re-action? But in many other cases we shall find the existence of the same chronic diseases not in any degree preventing the development of the usual symptoms of softening of the brain. Lastly, shall we refer the circumstance to the advanced *age* of the persons? This reason would not be more available than the others; for, though one of the patients was an octogenarian, another was only forty-five years of age. Let us here acknowledge, then, our complete ignorance; and, in reference to these facts, to which we find analogous ones in respect of each lesion that occurs, let us recall to mind a principle which cannot be too often repeated, viz. that the alterations of texture which an organ has undergone do not necessarily occasion a derangement of its functions. Thus there are organic lesions without symptoms, as there are symptoms without any appreciable lesion that can account for them."

To those who are engaged in the examination of dead bodies with a view to trace the connection between the symptoms of diseases and the morbid alterations of structure that produce or accompany them, it must obviously be of essential importance to distinguish, in particular cases, those alterations of structure that had existed during life, without giving any outward indication of their existence, from those on which the symptoms that manifested themselves really depended. The observation of some cases in which the coronary arteries of the heart (the vessels by which the substance of this organ is supplied with blood) were found after death to be ossified, in persons who during life had exhibited the symptoms of the painful affection of the chest termed *angina pectoris*, led some practitioners to conclude that they had detected, in that alteration of structure, the proximate cause of this disease. More extensive observation, however, has shown that ossification of the coronary arteries often exists without the symptoms of *angina pectoris*, or even without any symptoms whatsoever, manifesting themselves; as it has also shown that the symptoms of *angina pectoris* may occur in persons whose coronary arteries are sound. In the same way some recent pathologists have endeavoured to establish that asthma depends, in all instances, upon organic disease of the heart; though it seems to be well established, by the researches of accurate observers, that, though asthmatic symptoms and structural affection of the heart are frequently conjoined, every form of organic alteration may exist in the heart without inducing the symptoms of an asthmatic paroxysm; and that in many persons liable to such paroxysms, there exists no alteration in the structure of the heart. "One who would investigate diseases among the dead," as was remarked by an author formerly referred to (Dr Thomas Simson, in the Edin. Med. Ess. and Observ. vol. v. p. 617), "should have a large history before him of what the living can bear without disturbance. If this had been always the qualifications of our dissectors, in what different light should our histories of diseased bodies appear. And, in consequence of this, physicians should not have been so far misled in advancing the causes of diseases, and of the death of their patients, as to have placed every irregularity found as the original of the symptoms they had observed in life. A cautious theorist can never be satisfied in his inquiries till he has found out the disorder whence he can deduce all the symptoms that had appeared to him, by easy and natural consequences. A disorder that he observes upon dissection that has no apparent connection with the apparent disorder that happened in the actions of his patient, must be passed by him as foreign to his inquiry, or is only to be left on record to see if others may afterwards find the connection; but till then, such a disorder can never justly be advanced as the cause of any particular disease."

After the preceding view of the circumstances under which an organic or structural morbid affection of some part or other of the body may escape detection, in consequence of its not giving rise to any perceptible alterations in the exercise of the functions of the economy generally, and more particularly of the functions of the part in which it is situated, we come next to consider those sources of difficulty and fallacy in diagnosis, from which it arises, that although morbid phenomena or symptoms do manifest themselves, it is under circumstances calculated to create an uncertainty as to the nature and seat of the pathological condition on which they depend, or even to excite a belief in the existence of morbid conditions very different from those that actually exist.

In the first place, then, groups or trains of symptoms arising from different pathological conditions, may be identical, or at least so similar as to render their discrimination exceedingly difficult, if not impossible. In some cases, this similarity or identity in the groups of symptoms produced by different pathological conditions, is constant, so that the well-informed practitioner is on his guard against the risk of mistake. But, in other instances, a pathological condition usually recognisable by a group or train of symptoms peculiar to itself, assumes appearances foreign to its own habitual or ordinary character, and such as usually accompany some other form of morbid condition, so that the practitioner is taken, as it were, unawares, and exceedingly liable to adopt an erroneous opinion as to the nature of the disease which he is proceeding to treat. From the illustrations to be quoted, it will be seen that when different pathological conditions or proximate causes give rise to the same group or train of symptoms in different persons, they may have their seat in the same organ, or in different organs. In either case it may be that both the morbid conditions are of an organic character, or that the one is organic and the other dynamical.

We shall, in the first place, adduce some examples of organic pathological conditions, differing in nature, but corresponding in seat, which give rise to groups or trains of symptoms so similar, as to render it difficult, if not impossible, to say, during life, with what morbid condition the patient is actually affected. M. Andral, after describing the different morbid alterations of the mucous membrane of the stomach, and of the subjacent textures, that may arise from chronic inflammation (including cancer, according to the view which he takes of the nature of this disease), puts the question, whether the infinitely varied lesions which he has described are each of them marked by a peculiar train of symptoms? "We do not fear," says he, "to answer in the negative. With the exception of some symptoms that are the mechanical result of the obliteration of the cardia or of the pylorus (the two apertures of the stomach) by a tumour, the same phenomena most generally attend during life these so different alterations of form and of structure." (*Malad. de l'Abdomen*, p. 429.) In speaking of the symptoms of diseases of the liver, the same author says, "they are few in number, often too obscure or too little marked to enable us from a consideration of them always to affirm the existence of an affection of the liver. In other circumstances there is no room for doubt as to the existence of an affection of this organ; but it is very difficult, or even impossible, to determine its nature. For, on the one hand, analogous symptoms are often produced by affections of the liver which present the greatest differences in respect of their anatomical characters; and, on the other hand, we cannot say that in any of these affections we find any particular symptom constantly present." The same principle is applicable to the diseases of the urinary organs. Dr Marcet, after enumerating the symptoms generally produced by calculi in the kidneys, or by their passage into the bladder, adds (lib. cit. p. 13), "yet the occurrence of these symptoms cannot be considered as an absolute demonstration of the existence of this disease, unless calculi have been actually discharged; since it is well ascertained that symptoms very nearly similar are also sometimes occasioned by mere inflammation of the kidneys, without any concretion being present."

Before pointing out examples of an organic and a dynamical pathological condition of the same organ producing similar or identical groups or trains of symptoms, it may not be amiss to suggest of how much importance it is that the physician should be able to ascertain whether the proximate cause on which the symptoms in a particular case of disease depend, is organic or dynamical, since, according to the conclusion he may form on this point, the general plan and objects of treatment must be very materially influenced. It is in the class of dynamical diseases chiefly that the efforts of the medical art are likely to be of avail. Of organic diseases there is a very large portion in which, though we may for a time retard their progress, or alleviate the sufferings to which they give rise, we can entertain very little or no rational expectation of effecting a cure. The distinction between an organic and a dynamical disease of the same organ is one, however, which, in practice, it is very far from being at all times easy to make. The existence of an organic disease can, indeed, frequently be ascertained by direct observation, or by what may be called its physical indications or signs, as when it is seated in external parts, or in parts which the practitioner is able to examine by sight or by touch, directly or with the aid of instruments. In this mode of investigation a correct knowledge of the geography of the body, if we may so speak, is obviously essentially necessary. The practitioner must know the ordinary position of each part, its extent and its relations to the other parts in its neighbourhood. He must know in what situations to expect a prominence, and in what a depression; where to expect to find a soft and yielding part, and where a part that is hard and resisting. But even where he is able by direct observation to ascertain the existence of an organic disease, he often derives from this no knowledge of its particular nature, no information, for example, as to whether a tumour is simply inflammatory or scrofulous, whether it is of a mild or of a malignant nature; nor consequently does he obtain any insight into its probable progress: and in a great many of the organic alterations which occur, from the deep and remote situation of the parts which they occupy, as in diseases of the brain, for example, he is not apprized by direct observation, even of their existence. For all that remains to be learned respecting organic diseases, their existence, their nature, and their seat, after the means of investigation deducible from direct observation, or from what we have called their *physical* indications or signs, have been exhausted, the practitioner must, as for the whole of his knowledge of dynamical diseases, be entirely dependent on the detection of deviations from the regular exercise or performance of the several functions of the body, or of what may be termed the *functional* indications or signs of diseases. Hence it is obvious of how great importance an accurate knowledge, both of the healthy phenomena of the economy (as embraced in the science of physiology), and of the various modifications which these phenomena are liable to undergo in the state of disease (the branch of general pathology termed Symptomatology, or Semeiotics), must be to the practitioner of physic.

We may now point out some examples of an organic and a dynamical disease of the same organ, producing groups or trains of symptoms apparently identical. In diseases of the brain, the same train of symptoms may arise from an obvious organic alteration, or without any such alteration, and, as it is usually expressed, from mere functional disturbance. "A person previously in perfect health," observes Dr Abercrombie (On Diseases of the Brain, 3d edition, p. 199, 200), "falls down suddenly, deprived of sense and motion, and dies after lying for some time in a state of coma. We find, on examination, a large coagulum of blood compressing the surface of the brain, or filling its ventricles, and the phenomena of the disease appear to be distinctly accounted for. Another person is cut off with the same symptoms, but nothing is met with except serous effusion in no great quantity in the ventricles, or only on the surface of the brain. A third is seized in the same manner, and dies after lying for a considerable time in a state of coma, from which nothing can rouse him for an instant; and, on the most careful examination, we cannot detect in his brain the smallest deviation from the healthy structure." Here, then, are three cases which, as presenting the same external phenomena, all fall under the same nosological disease, apoplexy; but of which the first may be regarded as depending on an organic, and the last, at least, on a dynamical affection; whilst with regard to the second, it may not be easy to determine whether the morbid appearances discovered after death should be regarded as the primary disease, or only as one of its effects.

The stomach may be mentioned as another organ the structural and dynamical affections of which give rise to closely resembling groups or trains of symptoms. "To trace exactly the phenomena of a disease," says M. Chardel (lib. cit. p. 159), "is not always sufficient for conveying a proper knowledge of it; it is still necessary to point out any other affections the resemblance of which with the object of our researches might possibly occasion mistake. This observation is of especial importance in the case of incurable diseases, since, to confound these with other diseases that are susceptible of cure, is to deprive the unfortunate persons committed to our charge of the assistance which they had a right to expect, and to deceive their confidence. No affection," this author proceeds to observe, "simulates so completely scirrhous degenerations of the stomach as spasmodic vomiting, or that arising from an immediate lesion of the principle of life in the nerves of the stomach, from a special sensibility of that viscus."

Of different organs,

In other instances in which different pathological conditions or proximate causes give rise to the same group or train of symptoms in different individuals, the different lesions have their seats in different organs or parts of the body. These organs or parts may be related to one another simply in the way of contiguity or superposition; or there may exist some functional dependence or sympathetic connection between them.

related by proximity;

The mistakes liable to occur in the judgments of medical men as to the existence or non-existence of aneurism, furnish an illustration of the similarity that may exist in the morbid phenomena induced by different pathological conditions of organs or parts in near proximity. "The occurrence of a pulsating tumour in the vicinity of an artery," says Mr Hodgson (Diseases of Arteries and Veins, p. 88), "will induce every cautious surgeon to suspect the existence of an aneurism. But there are many diseases which, from their situation, or from other circumstances, may assume the symptoms of aneurisms; and in some instances aneurisms assume the appearances of other diseases." "The circumstances that characterize the existence of an aneurism are much more complicated when the disease is situated in the thorax or abdomen, than when it exists in the extremities. Aneurisms in the thorax or abdomen frequently prove fatal before a knowledge of their existence is confirmed by that evidence which the appearance of the tumour externally generally affords; and the viscera with which they are surrounded are subject to a variety of diseases, many of the symptoms of which are common also to aneurisms of the aorta and of its primary ramifications."

If we turn our attention to the diseases of particular organs, we shall find ample illustrations of the source of fallacy in diagnosis to which we have just alluded. Practitioners are well aware that a difficulty of breathing or of swallowing may arise not only from affections of the organs by which these functions are respectively exercised, but from morbid conditions of one or other of the neighbouring organs or parts, as of the thyroid or bronchial glands, the vertebræ, and the larger blood-vessels; and also, that whilst difficult respiration may be occasioned by morbid conditions of the pharynx and œsophagus (the organs by which deglutition is effected), difficulty of deglutition may arise from morbid conditions of the glottis, of the larynx and trachea, and even of the lungs, that is to say, of the organs of respiration. "Aneurisms arising from the thoracic aorta," Mr Hodgson has remarked, "by compressing the trachea and œsophagus, produce great impediments to respiration and deglutition, and are often mistaken for diseases of the lungs, or strictures of the œsophagus." (P. 91.) M. Cruveilhier, in speaking of the diagnosis of inflammation of the larynx, remarks, that "a very serious error, and, at the same time, one very easily committed, is the referring to inflammation of the submucous membrane of this organ the effects of the compression of the trachea by an aneurism of the arch of the aorta. Nothing resembles more a paroxysm of suffocation produced by laryngitis than the dyspnœa occasioned by the pressure of an aneurismatic aorta upon the windpipe. I have myself," he adds, "been on the point of committing this error so much the more easily that the individual submitted to my observation was at the same time affected with hoarseness of the voice." (*Dict. de Méd. et Chirurgie*, xi. 35.)[1]

"As to the symptoms of splenitis," says M. Andral, "their great obscurity depends on several causes; for, 1*st*, as the functions of the spleen are unknown, their disturbance cannot reveal its morbid condition in the same way as the disturbance of digestion reveals an affection of the stomach; and, 2*dly*, the symptoms produced by inflammation of the spleen must be easily confounded with those arising from inflammation in one of the surrounding organs, and *vice versa*." (*Diction. de Médecine*, art. SPLENITE.) "The symptoms of the diseases of the pancreas," it has been remarked, "are obscure, being for the most part such as belong equally to morbid affections of other parts contained within the abdominal cavity. It is, indeed, very seldom that we are able to discover pancreatic disease in the living subject." (Dr Carter, art. PANCREAS, in the Cyclop. of Pract. Medic.) "From common experience," remarks another author, "and the evidence of morbid dissection, it may justly be inferred that disease of the pancreas is a rare occurrence; yet the difficulty of ascertaining the condition of this organ in the living subject, by any other symptoms than such as are secondarily manifest in the stomach or liver, must render our judgment in many cases uncertain, and our practice, doubtless, sometimes erroneous." (Dr Percival, Trans. Assoc. Phys. in Ireland, vol. ii. p. 128.)

We have seen, in respect of the kidneys, the difficulty of distinguishing, by the symptoms that manifest themselves, between the different affections of which these organs may be the seat. But besides this, they also afford proofs of the difficulty of distinguishing between the morbid conditions of a particular organ and those of the parts in its vicinity. "The diseases of parts near to the kidneys," says Chopart, in reference to the diagnosis of renal calculus (lib. cit. p. 182), "may be accompanied with symptoms closely resembling those which manifest themselves in calculous nephritis. Have there not been found, in persons believed to be nephritic, scirrhus, abscesses, and calculi of the pancreas, or of the mesentery; the spleen scirrhous, displaced and lying upon the kidney; a tumour of the intestines resting on that viscus, &c.? Other facts of the same nature might be adduced in confirmation of the difficulty that exists in judging of the presence of calculi in the kidneys. But if in some cases we cannot arrive at certainty, we may at least have strong presumptions respecting this disease, by combining all the symptoms, and comparing them with one another."

It is proper to be kept in mind, that the resemblance in the symptoms produced by morbid conditions of organs related to one another by proximity, may show itself either in physical or in functional indications. Of resemblance in physical indications, we may take an example from M. Chardel, who, in pointing out certain circumstances under which scirrhus of the stomach may exist without any tumour being perceptible in the epigastric region, suggests (lib. cit. p. 185) that, on the other hand, tumours really existing in some other organ, such as "a prominent liver, an abscess in the posterior cavity of the epiploa, or a swelling of the pancreas, may simulate an induration of the stomach. Tubercular mesenteric glands, when they are in the neighbourhood of the stomach, may easily be taken for a scirrhus of that viscus." And he adds, that "it is possible that the hardness which the muscles of the abdomen, particularly the recti, exhibit in persons in whom they are strong and much exercised, may equally lead into error." Of resemblance in functional indications, we may quote an instance mentioned by Mr Hodgson, who observes that "when an aneurism arises from the aorta at the root of the cœliac artery, it is attended with frequent sickness, more especially after food is taken into the stomach, and by its pressure produces symptoms like those of stricture of the pylorus." (P. 95.)

---

[1] See generalization of the same fact by Dr Cheyne, in the article LARYNGITIS of the Cyclopædia of Practical Medicine; and corroborative cases in the Lond. Med. Gaz. i. 322, and the Edin. Med. Surg. Journ. xliii. 293, the latter by Professor Graham. See case of aneurism of the aorta, producing symptoms of pneumonia, related by Rostan, Médecine Clin. i. 64; and on the difficulty of diagnosis in internal aneurisms, particularly abdominal, see case by Dr T. E. Beatty, in Dubl. Hosp. Rep. v. 166.

The reciprocal influence which the different parts of the body exercise upon one another, often throws great difficulty in the way of the practitioner in attempting, in particular instances, to ascertain the seat of disease from a consideration of the symptoms that attend it, seeing that the prominent symptoms may point at organs very different from those which are actually the seat of disease. This influence is sometimes exerted between parts that co-operate in the performance of the same general function, as when vomiting arises in consequence of obstruction of some portion of the intestinal tube; but in other instances it is exerted between parts concerned in the performance of functions essentially distinct, as when headach or palpitation of the heart occur in various derangements of the stomach and bowels. In consequence of this reciprocal dependency of different parts, not merely may a symptom immediately referrible to some particular organ depend on an affection of an organ quite distinct from this, but the same symptom may arise from affections of several different and remote organs. Thus, for example, the symptom of cough, the immediate cause of which is known to be the convulsive or rapid contraction of certain respiratory muscles, may occur as a symptom of various affections of the air-passages or lungs; but it may also form a very prominent symptom in diseases having their seat in parts remote from the respiratory organs; and a late French author, M. de Larroque, has published a work professedly treating of cough as a symptom, more or less severe, of certain abdominal diseases. The circumstances just adverted to render it impossible, it may be remarked, to characterize and recognize diseases by one particular prominent symptom. It is only by marking and analysing the concomitant groups of symptoms that we can arrive at a knowledge of the organ which is the primary seat of disease. When a patient complains of headach, for example, the practitioner must judge, from a consideration of the other symptoms by which this uneasy feeling is accompanied, whether it depends on the existence of some pathological condition in the head, the immediate seat of the symptom, or in the organs of digestion, the derangements of which we know to be capable of inducing it sympathetically. In the same way, when the outstanding or prominent symptom is vomiting, it is only by a careful consideration of the concomitant circumstances that we can hope to determine whether it is in the stomach itself, or in some other organ more or less immediately connected with it, that the original seat of mischief is to be found.

"The general signs by which pericarditis may be recognised," says Mr Adams, "are exceedingly equivocal, and much requires to be done by the physician to clear the obscurity. I have been frequently called upon to examine the bodies of persons supposed to have died of disease of the lungs or liver, and I have found pericarditis the true and single source of death, although during the previous illness the heart was never suspected to be the seat of a fatal affection. I have myself been witness to the treatment of a case of chronic inflammation of the pericardium in a girl aged fourteen, which terminated fatally, and during the whole progress of the disease, phthisis, or rather what was considered hepatic phthisis, was the disease under which this child was supposed to be gradually declining." (Dubl. Hosp. Reports, iv. 360.)

Morbid conditions of the alimentary canal are peculiarly liable to produce disturbance in the functions of some other organs, without betraying their own existence. "Such," says M. Piorry, in an essay on the influences which the stomach exercises on other organs in health and in disease (*Journ. Complem. du Dict. des Scien. Méd.* xvi. 199), "such is frequently, in diseases of the stomach, the intensity to which the sympathetic lesion of the related organs amounts, that it seems to destroy the primary affection, or at least to cause it to be overlooked. Whilst the patient labouring under such disease experiences only slight uneasiness in the epigastrium, he is tormented by the severest and most intolerable cerebral, muscular, thoracic, and other pains." "The exact appreciation of the nature of the symptoms observed," remarks the same author, "is so much the more difficult on this account, that the organ whose sufferance is symptomatic of the lesion of another part becomes itself a new centre of irradiation, which induces, in its turn, secondary irritations or pains. And as there is nothing to prevent these from being, in their turns, new points of departure of physiological influences, there results excessive difficulty in establishing a just diagnosis, in cases so embarrassing." Every one is aware of the influence which the presence of worms in the intestines is generally believed to exercise in producing derangement in the functions of remote organs. "There are few diseases," says M. Andral (*Fievres*, p. 273–5), "particularly in children, of which worms have not been supposed to be capable of being the cause. Klein has said, 'Nullum tam peregrinum est symptoma, tamque δαιμονιακον, quod vermes excitare non possint.' We read in authors numerous examples of palsies, comatose attacks, asthmas, palpitations of the heart, obstinate coughs, epilepsies, and hysterical convulsions, depending on that cause. Even tetanus has been considered as the result of the presence of worms in the intestinal canal. In the time of Alexander Trallianus, it was said that, when worms passed from the small intestine into the stomach, they gave rise to excruciating cardialgia, to syncope, and that sometimes even they occasioned sudden death. It must be confessed, that observations of this kind become the less frequent as pathological anatomy is more generally and more carefully cultivated. But, in hesitating as to the reality of these extraordinary facts, let us be careful not to deny altogether their possibility. A hemiplegia caused by worms would not appear to us a less credible phenomenon than a palsy succeeding to the introduction of particles of lead into the alimentary passages. Now nothing, unfortunately, is more real and more common than this last species of palsy. The symptoms caused by worms may, besides, be expected to vary much according to their nature, their number, their greater or less mobility and activity of existence, their more or less immediate contact with the mucous membrane, their situation in particular parts of the alimentary canal, the energy of the patient's sympathies, his nervous susceptibility, &c. Amongst physicians, said De Haen, some have made worms play too important a part in the production of diseases; and others have not paid sufficient attention to them."

Lesions of nervous centres producing symptoms in remote organs.

To the class of cases in which different pathological conditions, having their seats in different organs or parts of the body, give rise to the same group or train of symptoms, may be referred those in which lesions of the central, or cerebro-spinal and ganglionic, portions of the nervous system occasion the development of symptoms in remote organs of the body, similar to those that are produced, or that may be supposed to be produced, in these organs, by morbid lesions of which they are themselves the immediate seats. In many cases, for instance, of local pains or neuralgias, as of neuralgia of the mamma, of the intercostal muscles, and of the arm, there is reason to believe that the pain is not attributable to an affection of the nerves of the parts to which it is referred, but (as Drs Brown, Darwall, Teale, and other authors, have pointed out) is caused by the presence of a primary diseased state in the spinal cord itself, or in its coverings. Although our limits do not allow us to enter fully into the illustration of the doctrine of spinal and ganglionic irritation, as it has been called, we cannot refrain from quoting a very graphic account of the diversity of symptoms manifested in this class of cases, which is given in a paper on diseases simulating acute inflammatory attacks of various important organs, by Mr Torbet, surgeon in Paisley, contained in the forty-fourth volume of the Edinburgh Med. Surg. Jour. p. 375. "Of the diseases in question," says that author, "females frequently before, sometimes after, puberty, are the most usual victims. The individuals are of what is called irritable constitution, a peculiarity moreover distinctly hereditary, and connected more or less with strumous diathesis. The morbid train of neuralgic symptoms is most usually set in operation either by a serious inflammatory or febrile disease, by excessive fatigue, or by injury, as from a heavy lift or severe fall. The severity and variety of diseases to which the individuals appear to be liable, might almost characterize the affection. You are astonished to hear of their violent illnesses, the powerful remedies that are applied, and the rapidity with which they shake off these attacks. In severity their diseases resemble those of no other persons. They are paralytic, blind, speechless, without food, and without sleep, for weeks or months, and yet they do not die. Is the head the organ affected? Then they have headach, of which no words can convey an idea, ending perhaps in insensibility; or there is a heavy weight pressing down their eyelids, a tight bandage compresses, or hammers beat within their heads, bells ring in their ears, vertigo and sickness overpower them, noise and light disturb them. Is the chest affected? Then a sepulchral cough, each fit of which seems to threaten existence, over which medical art seems to possess no control, harasses from morning to night, and night to morning. There is excruciating pain in the chest, especially during the cough, which is perfectly devoid of expectoration. There is a feeling of swelling and choking at the under part of the neck, tremendous palpitation of the heart; the pulse is quick and agitated, but varying greatly with the severity of the cough; and the heart's pulsations seem to occupy the whole left side of the chest. Is the digestive apparatus the seat of disease? Then ensue vomiting without apparent cause; incessant retching for hours, occurring perhaps every day for weeks, without any thing being vomited; no appetite; unquenchable thirst; occasional severe pain in the belly, or muscular cramps; and costiveness alternating with diarrhœa, the stools being unaccountably copious. Are the organs of voluntary motion attacked? Then there are cramps, prickling or numbness, sometimes severe spasms, liker tetanus or hydrophobia than any thing else, ending possibly in catalepsy; or paralysis of one or more limbs ensues. Such is an epitome of the symptoms of the more violent cases; but almost endless variety must of necessity occur, according as the several nervous centres are affected, and their affections modified by individual circumstances. It is precisely from this variety and anomaly of appearances that practical men are apt to be misled. The most marked symptoms are apparently so distant from, and unconnected with, nervous irritation, and are moreover so violent and similar in their character to pure inflammatory diseases, that there is great risk of our chief curative efforts being directed to the appendages and coincidents, instead of attacking the disease itself."

Lesio of nervo trunk p. ducin symp s at the branc

Numerous facts upon record show that a pathological condition existing in the trunk of a nerve may produce symptoms that appear referrible to the organ in which its branches are distributed. "Every part to which a nervous filament can be traced," as is remarked by Sir Benjamin Brodie (Lectures illustrative of certain Local Nervous Affections, p. 2), "may be said to have its corresponding point in the brain or spinal marrow; and an impression made either at its origin, or anywhere in the course of the trunk of a nerve, will produce effects which are rendered manifest where the nerve terminates, at that extremity of it which is most distant from the brain." The experiments of different physiologists had fully established, that when the pneumogastric nerve, or the recurrent branch of this nerve, which goes to the larynx, is divided on each side of the neck, paralysis of the muscles that open the glottis is produced, and, as a consequence of this, the state of stridulous breathing. The knowledge of this fact has been very ingeniously applied by the late Dr Hugh Ley to the explanation of certain affections of respiration occurring as consequences of disease. Thus he conceives that the crowing or croup-like inspiration which is not unfrequently met with in infants, depends primarily, not on a morbid state of the parts constituting the glottis itself, but upon a morbid condition of the pneumogastric and recurrent nerves; and that in very many instances it is connected with a diseased state of the lymphatic glands of the neck, producing pressure upon these nerves. He has endeavoured likewise to show, that the fits of dyspnœa and stridulous breathing, which patients affected with tumours, aneurisms, or other organic diseases at the root of the neck, sometimes experience, as well as the asphyxia by which such persons are not unfrequently cut off, are often attributable, not to any mere physical or organic compression upon the trachea or larger bronchi, but to the diseased masses being so situated as to cause compression, stretching, or more or less complete destruction, of the pneumogastric nerve, or its recurrent laryngeal branch. (On Laryngismus Stridulus.)

Lesio of remot r. gans ducin symp s in ne us centre

But whilst morbid conditions of the central parts of the nervous system frequently give rise to groups or trains of symptoms that seem referrible to distant organs, on the other hand it sometimes happens, as M. Lallemand has remarked, that diseases having their seat elsewhere than in the brain produce phenomena analogous to those occasioned by certain cerebral affections. (Preface, p. 20.) M. Andral relates (*Malad. de Poitr.* vol. ii. p. 444) a case in which the symptoms that manifested themselves during life were those of inflammation of the membranes of the brain, whilst the morbid appearances found after death were those of acute inflammation of the serous membrane of the heart; and he refers to a case related by M. Rostan, in which there occurred cerebral symptoms, for the explanation of which no other lesion was found than that of inflammation of the investing membrane of the heart. "These two cases," M. Andral remarks (p. 447), "are well calculated to show, that in consequence of individual susceptibilities, there is no organ the lesion of which may not induce the most varied nervous symptoms, so as to produce sympathetically the different morbid states (*i. e.* nosological diseases) of which we place the seat in the nervous centres and their dependencies. It has been correctly laid down, that the alimentary canal, when inflamed, re-acts, more frequently than any other organ, upon the brain, and gives rise to the symptoms of inflammation of the membranes or substance of the brain. But it is not less true, as M. Boisseau has already very well shown, that inflammations of other organs may equally produce, by their sympathetic influence on the encephalon, the different groups of symptoms which constitute the ataxic fever of M. Pinel." Dr Latham, too, after remarking that the perplexities with which the diagnosis of the diseases of the pericardium is beset, are more considerable than any belonging to the inflammatory class of diseases in other organs of the body, has mentioned some cases in which the symptoms that manifested themselves during life were those which usually attend inflammation of the brain, whilst, upon examination after death, the brain and its coverings were found in a perfectly healthy and natural state, and the pericardium alone, or conjointly with the substance of the heart, discovered unequivocal marks of acute and recent inflammation. "These cases," Dr Latham continues, "furnish specimens of the enormous difficulties which medical men have sometimes to contend with in the diagnostic part of their art, and they ought to mitigate the censure of those who would judge harshly of our mistakes. Here it is remarkable, first, that a vital organ should sustain an acute inflammation without any symptom whatever immediately referrible to itself, and that organ the heart; and, secondly, that it should impart expressly to another organ, not the mere symptoms of common derangement, but the authentic symptoms of inflammation, and that organ the brain. Diagnosis is necessarily perplexed and baffled where no symptoms whatever are found in the organ really diseased, and none in those with which it is functionally allied, but in some other organ with which it has no known connection, save that they are both parts of the same body. And, further, diagnosis becomes absolutely hopeless when the organ, thus suffering sympathetically, puts forth, not the sign of a mere indefinite ailment, but of a real disease, changing and disorganizing its structure; as when the brain, being perfectly healthy, manifests the signs of acute inflammation, while the heart, being acutely inflamed, gives no evidence of its disease whatever."

Of the cases in which the medical practitioner is misled by the symptoms that present themselves, as to the nature of the malady under which his patient is labouring, this arises, in some, from a local affection producing the symptoms of a constitutional disease, without betraying any marks of its own existence; whilst in other instances, on the contrary, it depends upon a constitutional disease, simulating, or producing the symptoms of a local affection.

A learned journalist, in quoting a case related in Hufeland's Journal by Dr Roeser of Wurtemberg, in which inflammation of the heart had assumed the symptoms of chorea, or St Vitus's dance, has justly remarked, that "the medical practitioner is not unfrequently puzzled by nervous affections taking on the character of serious organic diseases; he should be on his guard against the reverse, dangerous maladies concealed under the mask of nervous disorders." (Johnson's Journal, July 1829.)

"In local diseases," says Sir Everard Home, in his work on Strictures (ii. 13), "it is often difficult, and sometimes impossible, to ascertain whether the constitutional affections that are met with are in reality symptomatic of the local irritation, or belong to some new disease which has been superinduced; and for want of some criterion to guide our judgment in the investigation of diseases, we too often mistake the occasional symptoms for the disease itself, which, from the obscurity of its situation, or its apparent insignificance, is totally neglected." "The constitutional symptoms which belong to a stricture in the urethra," he adds, "have been more frequently mistaken for an original disease, than those of any other local complaint; and it is only within these few years that this error has been detected." And to the same effect Dr Thomson observes, in his Lectures on Inflammation (p. 105), that "of fevers resembling intermittent, and arising from local diseases, we have examples in the febrile affections which not unfrequently accompany strictures in the urethra. I have repeatedly known," he adds, "these symptoms mistaken for, and treated as, a true intermittent fever."

It is well known that the "new medical doctrine," maintained by M. Broussais, proceeds on the assumption that certain diseases usually regarded as constitutional or essential, that is, as not proceeding from nor depending on any local affection of a particular organ or texture, always result from certain local internal inflammatory affections, though in some instances there may not occur any well-marked symptoms indicative of the existence of such affections. "All the essential fevers of authors," says M. Broussais, "are referrible to gastro-enteritis (inflammation of the stomach, and adjacent part of the intestines), simple or complicated. Medical men have all overlooked this inflammation when unaccompanied by local pain; and even when pains have occurred, they have always been regarded as accidental." (*Propositions de Médecine*, cxxxix.) It would be out of place to enter here on an exposition of the errors involved in this fundamental principle of the so-called physiological doctrine of medicine; but whatever may be thought of the doctrine which represents all fevers as originating in and referrible to some local inflammatory affection, it must be allowed, that local inflammations occasionally assume the symptoms and course of particular forms of fever, so as to mislead the practitioner in his judgment as to the nature of the disease which he has to treat. "Before entering," says Professor Van Coetsem of Ghent (*Recherches Cliniques*, &c. p. 91), "on an elaborate discussion as to the diagnostic value of the local symptoms which manifest themselves during the course of acute arachnoiditis (inflammation of the serous membrane of the brain), we have thought it right to fix the attention of the medical public upon a singular modification of this inflammatory affection, of which we have hitherto in vain sought for any notices in the works of the different authors who have described this affection, if we except only Pinel and Morgagni, who relate with astonishment some scattered observations, which they have, as it were, left to their successors to make use of, when, having become more numerous, they might serve as the foundation for a medical doctrine applicable to analogous cases. We mean to say that this terrible inflammation may sometimes simulate the paroxysms of quotidian or tertian intermittent fever. This result, founded directly on observation, is of the highest importance as regards the treatment; for if, unfortunately, the physician deceives himself respecting the nature of the pretended febrile paroxysms, which are observed at the commencement or during the course of the disease, he loses successively all the patients committed to his care." "Resting on the observations of our predecessors, and on those which we have ourselves collected, we think we may affirm, without fear of being taxed with rashness, that there are acute inflammations of the serous system which sometimes affect the periodical form of intermittent fevers; and that, of these, acute arachnoiditis presents, during its course, more frequently than the inflammations of other serous membranes, the periodicity in question." (P. 121.)

Constitutional diseases may simulate local affections.

It would appear that under peculiar states of the general constitution, the groups or trains of symptoms characteristic of diseases appertaining to particular organs may manifest themselves, though there do not exist in these organs any morbid conditions, pathological states, or proximate causes, such as those upon which the occurrence of these diseases usually depends. Thus, for example, in certain states of the general constitution, all the symptoms which indicate an apoplectic attack may occur, whilst, from circumstances developing themselves in the progress of the affection, the practitioner has the assurance that no vascular turgescence of the brain, nor serous nor sanguineous effusion, such as genuine apoplexy depends upon, has actually taken place. As illustrative of those states of the general constitution in which such fallacious or simulating diseases occur, we may refer to that induced by the morbific agent which produces ague or intermittent fever, to the gouty habit or diathesis, and to the hysterical.

Ague.

We shall give a few illustrations of the influence of each of these forms of constitutional disease in inducing phenomena analogous to those of particular local affections; and, first, of ague. Sydenham, in the account he has given of the epidemic diseases which prevailed from the year 1675 to 1680, in speaking of the intermittent fevers of 1678, makes the following observation (*Epistola Responsoria, 1ma*, p. 22–3, edit. sec. Londini, 1685; also Works, London, 1742, p. 284, § 34): " Here it is proper to be noticed, that during the first years of this constitution, a very remarkable symptom sometimes succeeded these intermittents; for their paroxysms did not begin with chilliness and shivering, afterwards succeeded by a fever, but the patient was seized with precisely the same symptoms as if he had been affected with true apoplexy, though, however closely it resembled this affection, the ailment was nothing more than the fever itself attacking the head, as was shown by the colour of the urine and other symptoms. Although in a case of this nature all kinds of evacuations seem to be indicated for producing revulsion of the fluids from the brain, as is wont to be done in primary apoplexy, yet these means must be altogether abstained from, as being wholly opposed to the original cause of this symptom, viz. the intermittent fever, and endangering life, as I have myself known. But, on the contrary, we must wait till the paroxysm disappears spontaneously, at which time the bark, if it could not be administered at an earlier period, must be given as soon as possible, and sedulously repeated in the intervals between the paroxysms, till the patient be perfectly recovered."

Dr Morton, in his treatise *De Morbis Acutis, Universalibus*, published in 1692, has dedicated a chapter to the consideration of the proteiform character of intermittent fever. He observes that intermittent fevers are wont not unfrequently to assume the appearance of several other diseases, some of them of a very acute character. "These diseases yield to the power of bark, the great specific for the cure of ague; and if bark be not administered, they often prove fatal. No one hitherto," he continues, " so far as I know, has treated of this subject, though its investigation seems to me of the greatest importance for the promotion of practical medicine. Among the innumerable symptoms that usually accompany intermittent fevers, there is no one which does not sometimes rise to such a degree of intensity as to bring the life of the patient into immediate danger, whilst at the same time the type of the fever, in its various stages of chill, heat, and sweating, is completely obscured, so that we are not able to detect the existence of the fever by its usual characters. Sometimes it presents itself to the physician under the mask of a fatal chill; sometimes of an unceasing vomiting, of a griping diarrhœa, of cholera morbus, of colic, of periodical hemicrania, of apoplexy, syncope, rheumatism, of universal spasm, pleurisy, peripneumony, pleurodyne, or of some other disease; and though the remedies be administered that are suitable to the particular disease the form of which it assumes, no benefit is obtained from their use, and it is only by the administration of bark that the symptoms are relieved." (Exercitat. i. chap. ix.)

The class of cases to which Sydenham and Morton refer in the passages which we have quoted, have generally been designated as instances of *larvated* or *masked* intermittent fever. But they have not at all times been distinguished with sufficient accuracy from other instances of intermittent fever, in which the symptoms of some severe local malady have manifested themselves in complication with, and not to the exclusion of, the ordinary febrile symptoms of ague; a form of disease to which, from its dangerous character, and frequent rapidly fatal termination, the name of pernicious intermittent fever has been given by Torti and other writers on this subject.

Gou

That the gouty or arthritic constitution frequently gives rise to phenomena which simulate very accurately the symptoms of local diseases, although the usual proximate causes of these diseases do not exist, the following passages from Musgrave, a very distinguished writer upon gout, may satisfy our readers. " The diagnosis of anomalous arthritic affections," says this author (*De Arthritide Anomala*, Exoniæ, 1707, § iii.), " is surrounded by a great many difficulties, and involved in very deep obscurity." " Indeed those anomalous affections which occur without being preceded by any regular paroxysm of gout, imitate so closely the legitimate and well-marked diseases of the parts which they affect, that it may be considered wholly impossible to discriminate between them. If, for example, angina or quinsy occurs in a person previously healthy, and who has never suffered a single paroxysm of gout, nor shown any tendency to it, and no point of difference can be detected between the symptoms of this case and the ordinary ones of genuine angina, who would dream that this affection was dependent on gout? yet that a gouty angina may occur under such circumstances is established by medical experience beyond all possibility of doubt." " With regard to the inward part or trunk of the body," observes Musgrave (lib. cit. § viii.), " anomalous gout most frequently seizes upon the stomach and intestines. Hence arise anorexia, dyspepsia, vomiting; hence colic, dysentery, diarrhœa, and hence sometimes arthritic abscess. Frequently it attacks the head, exhibiting at one time the appearance of vertigo, at another of headach, and at another of arthritic apoplexy. Not unfrequently it makes its attack upon the region of the chest and the organs of respiration, presenting itself under the form of asthma, or of cough, or of hœmoptysis, or of arthritic phthisis. Sometimes it even attacks the fauces, assuming the characters of angina; sometimes the gums, receiving the name of gout in the teeth. Sometimes, in seizing upon the kidneys, it produces the symptoms of calculus, dysuria, and strangury. In fine, it lays hold of the viscera, the membranes, the muscles, the glands, the tendons, the ligaments, perhaps even the bones; so that throughout the whole trunk there can scarcely be found a part which is totally exempt from it." " It is well ascertained," adds this author in another place, " that the affections thus produced by this wandering poison (*devio miasmate*), simulate most accurately all the diseases to which the parts in which they occur are subject; assume their characters, exhibit even their pathognomonic symptoms, and can in no ways be distinguished from the indigenous diseases by the concurrent diagnostics, but, on the contrary, are in fact frequently confounded with them."

Hyst

We have mentioned hysteria as another of those states of the general constitution that are liable to give rise to groups or trains of symptoms closely resembling those which are in wont to arise from morbid conditions of particular organs. Sydenham, in speaking of hysteria, observes (Works, uti cit. p. 370), that " this disease is not more remarkable for its frequency, than for the numerous forms under which it appears, there being scarcely any diseases with which mankind is afflicted, of which it does not assume the semblance. For, of whatever part of the body it may take possession, it immediately produces symptoms corresponding to that part, so that unless the physician be a person of judgment and penetration, and of considerable experience in practice, he will be deceived, and suppose these symptoms to arise from some essential disease of this or that particular part, and not from the hysterical affection on which it really depends."

"Among the diseases which Sydenham had observed to be counterfeited by hysteria," says an able writer in Rees' Cyclopædia (art. HYSTERIA), "are apoplexy, which terminates in hemiplegia, and is chiefly seen in lying-in women, after difficult parturition attended with great hæmorrhage: the clavus hystericus, or acute pain in one small spot in the head, which is often accompanied by vomiting and palpitation of the heart; this is most frequent in delicate and chlorotic girls: pain in the stomach, cholic, with porraceous vomiting, resembling the iliac passion, terminating in jaundice, and always accompanied by great despondency; chiefly attacking women of lax fibre, who have suffered severe labours from large children: pains in the kidneys and bladder, like fits of the stone, with suppression of urine; occurring in women much debilitated by previous hysteric fits, and in a bad state of health, who are also liable to long-continued vomiting and diarrhœa without pain, discharging green bile. He likewise remarks, that the disease is liable to attack the external parts and muscular flesh, sometimes causing pain, sometimes swelling, in the throat, shoulders, hands, thighs, and legs, more especially in the last, which swelling, however, is to be distinguished from œdema, by being greatest in a morning, by leaving no pit after pressure with the finger, and by commonly affecting only one leg, though its external appearance much resembles that of œdema. But the most severe of those pains is that which affects the back. Sydenham adds, that these pains have this circumstance in common, that they all leave the parts extremely sore and tender, as if they had been severely beaten, so that they cannot bear the touch for some time; and that these pains and other symptoms are all preceded by a death-like coldness of the external parts." (*Diss. Epistolaris*, edit. sec. Londini, 1685, p. 124, seqq. Works, ut supra cit. p. 370.)

Dr Ferriar, in his essay on the Conversion of Diseases (Med. Hist. and Reflections, ii. 17), in speaking of hysteria, remarks that, "whoever would present us with a good book on the fallacy of symptoms, which is greatly wanted, must be completely master of this unaccountable disease." "I have met," says he, "with several cases of hysterical hœmoptoe, in which the quantity of blood evacuated was very considerable; six or eight ounces were sometimes spit up daily, for a fortnight or three weeks successively. Most of the usual symptoms attended which denote danger in this complaint when it arises from other causes; but the equal, moderate state of the pulse, and the appearance of some degree of the *globus hystericus*, seemed to determine the nature of the complaint; a conversion, accordingly, soon took place to the ordinary hysteric paroxysm, and no bad consequence followed the hæmorrhage from the lungs." "In one case," says the same author, "the bowels were attacked, and the symptoms of *enteritis* (inflammation of the bowels) were so precisely imitated, as to give much alarm for the patient's safety. I suspected the real nature of the disease from observing that the pulse was soft and full, that the evacuations were natural, and that her spirits were agitated, even to involuntary emotions, by slight causes.' This case terminated successfully on the accession of clear hysteric symptoms." "Several years ago, I attended an elderly lady, for a complaint which seemed to vibrate between apoplexy and palsy. After lying for several weeks in a state which afforded little hope of amendment, she saw affected with involuntary sobbing and weeping; the complaints in her head and limbs were converted into hysterical convulsions, and she recovered completely. It is very common to meet with syncope, or palpitations of the heart and great vessels, accompanied with a soporific depression, or extreme dejection of strength and spirits, and converted, after deep sighing or discharge of tears, into the hysterical paroxysm. In these cases the pulse is sometimes full and regular during the most alarming appearance of sinking; and sometimes variable to such a degree as to exclude all conjecture, excepting that of an hysteric origin." (Pp. 29, 30, 32.) It would be easy to swell to a large amount our quotations illustrative of the great variety of diseases which hysteria occasionally simulates. But we must content ourselves with referring to the account which Dr Marshall Hall has given in his work on Diagnosis (p. 214), of hysteric croup and hysteric pleurodyne; to some cases of hysteria imitating inflammatory action, paralysis, &c., which are related by Dr Bright in his very valuable Clinical Reports (ii. 452); and to a selection of cases presenting aggravated and irregular forms of hysteria, &c. by Mr Laycock, published in the 134th and subsequent numbers of the Edinburgh Medical and Surgical Journal.

In some cases it is not a single form of disease only of which an hysterical state of the constitution induces the phenomena, but several different forms of disease may be simulated in succession. "When the hysteric disposition is set in motion," says Dr Ferriar (p. 31), "it is not uncommon to find many of the different viscera attacked by it in turns, and the disease peculiar to each counterfeited with much exactness. I have seen symptoms of paralysis, jaundice, palpitation, and nephritis, succeed each other rapidly in the same patient, while some of the characteristic marks of hysteria have been discernible, and where the unity of the disease was proved, by the disappearance of all menacing affections on the approach of regular fits."

Difficulty of distinguishing between specific and non-specific diseases.

It is well known to medical men that there are certain diseases which possess what is called a specific character, that is, which depend on the introduction of a peculiar poison into the system, animal or mineral, such as those of syphilis, and of lead, or on a peculiar state of constitution, sometimes hereditary and sometimes acquired, such as cancer. These diseases, in their general features, resemble affections of a simple or non-specific character. Hence it is not unfrequently a matter of great difficulty, when affections present themselves resembling in their symptoms those which are known to be produced by specific diseases, to determine whether or no there exists in the constitution such a modifying influence as should communicate to these affections a specific character, or whether they be the results of diseased action in a constitution not peculiarly modified. Thus, it is well known how much controversy has arisen among medical men as to the possibility of distinguishing the various symptoms of syphilis from analogous affections occurring independently of the operation of the syphilitic virus. "There is hardly any disorder," says Mr Hunter, "that has more diseases resembling it in all its different forms than the venereal disease." (On the Ven. Dis. p. 380.) In the same way, it is, in many instances, impossible to judge, by the symptoms which present themselves, whether an affection, as of the breast, of the lymphatic glands, of the tongue, &c. ought or ought not to be considered as cancerous; and it is only the melancholy distinction of incurability that ultimately clears up the diagnosis. Again, when lead is introduced into the economy, as it may be in a variety of ways, it is liable to give rise to a certain combination of symptoms which, from the predominance of abdominal pains, and the retraction of the belly, bilious vomitings, and obstinate constipation, with which it is accompanied, is usually designated lead *colic*. But the symptoms of lead colic, as M. Andral has observed, sometimes manifest themselves in persons who have not been subjected to the influence of any saturnine preparation. (*Malad. de l'Abdomen*, p. 507.) To the same effect, Dr Graves, in the conclusion of a clinical lecture, published in the Lond. Med. Gaz. for 26th February 1831 (vii. 675–6), has suggested, “that perhaps the following *general law* will be found applicable to the effects which poisons produce on the constitution, viz. that all poisons give rise to a train of symptoms, constituting a certain disease, of which we may always find a counterpart among those diseases which arise in the system from other causes. Thus, symptoms exactly resembling those of colica pictonum (or lead colic) may occur where no lead has acted on the system; and the remarkable epidemic paralysis of the extremities observed in Paris in 1828 bears a striking resemblance to the paralysis caused by lead. If time permitted me to enter upon this subject,” adds Dr Graves, “I think I could succeed in bringing forward examples of morbid states of the system, in which symptoms similar to those arising from mercury, arsenic, narcotic poisons, &c. are produced totally independent of the ingestion of these substances.”

Resemblance of different diseases may be limited to their commencement,

The resemblance in the groups or trains of symptoms produced by different pathological conditions, which is liable to embarrass the practitioner, or lead him into error in forming his diagnosis, exists in some instances only during a particular period of the course of the disease, as at its commencement or termination. Thus, for example, a great many diseases, in their incipient stages, exhibit the general characters of fever, without any symptom manifesting itself by which the physician can be enabled to foretell whether, in its progress, the disease will prove to be of the nature of simple fever, or one of the various forms of febrile eruption, or whether an inflammatory affection is about to develop itself in one or other of the internal organs of the body. Unless there happen to be some adventitious circumstances, by which in such cases the judgment can be assisted, as, for example, the presumption afforded by the knowledge of exposure to a specific contagion, the practitioner must wait for a more advanced stage of the malady before he can pronounce with confidence upon its nature. M. Pinel, in noticing some remarkable varieties which mania presents at its first commencement, remarks, that “the extreme intensity of the symptoms may sometimes lead to error, and the name of mania may be given to a malignant or ataxic fever; for, besides that the same causes may equally produce one or other of these diseases, they may also exhibit common characters, violent agitations, furious delirium, alternations of stupor and nervous excitement; sometimes a marked acceleration of the pulse, dryness of the tongue, a pale and exhausted countenance, slight and interrupted sleep, and an entire rejection of all nourishment. The distinction is then difficult to make at the commencement, and it is only by watching the disease for several days that the practitioner can arrive at a positive conclusion.” (*Sur l'Aliénation Mentale*, Paris, 1809, p. 59–60.)

or to their termination.

As there is in many instances a close resemblance in the symptoms by which different diseases commence, so also it frequently happens that diseases of different natures, at an advanced stage of their course, give rise to some determinate group of symptoms which mask or conceal those of the primary disease, and themselves assume the prominent character. Thus various organic diseases situated in different organs or parts are liable to induce, at an advanced period of their progress, the state of dropsy; and when the dropsical effusion has once attained a considerable extent, it frequently masks the symptoms of the original disease so much as to render it difficult, if not impossible, to ascertain its nature, from the consideration of the existing symptoms. It would appear, however, from the results of recent clinical observation, that if the practitioner is able to ascertain in what situation the dropsical effusion commenced, and to trace its progressive extension to other parts of the body, these circumstances of themselves often afford sufficient data for determining in what organ the morbid condition is situated on which the production of the dropsy depends.

So much for the circumstances under which the practitioner may be embarrassed or misled in his judgments respecting the seat and nature of diseases, from resemblances in the group or train of symptoms produced by different pathological conditions. The next source of difficulty and fallacy in the diagnosis of diseases which we propose to illustrate, arises from the fact that the group or train of symptoms produced by a particular pathological condition, or concourse of pathological conditions, in one individual, may be very different from the group or train of symptoms produced by an apparently identical lesion in another individual. This production of two or more different groups or trains of symptoms in different individuals, by a pathological condition or proximate cause that seems to be identical, may occur, as will appear from the illustrations which we shall adduce, whether the pathological state or lesion be organic or simply dynamical.

The diversity in the group of symptoms attending a particular morbid condition, which misleads a practitioner in his diagnosis, may extend to the whole or greater part of the symptoms, or be confined to one symptom, or to a few only. In the latter case the deviation from the ordinary characters of the disease may consist either in the presence of a symptom or symptoms that do not usually attend the morbid condition which exists, or in the absence of symptoms by which it is usually accompanied. The disease drops, as it were, some of its usual characters, or assumes some that appertain to other diseases. “A disease,” says M. Rostan (*Méd. Clin.* ii. 355), “without being entirely latent, may want many of its characteristic symptoms; and this circumstance must occasion great difficulties in diagnosis. This is of frequent occurrence in cerebral diseases. Thus, when softening of the brain is unattended by precursory symptoms, its diagnosis is of extreme difficulty.” “Cerebral hæmorrhage,” says the same author, “may exhibit precursory symptoms, and cerebral softening want them. How, in such a case, can these two affections be distinguished?” Pain being a symptom to which the attention of the practitioner is always forcibly directed by his patient, much reliance is usually placed on its presence or absence in the diagnosis of diseases, and particularly in discriminating between those which are and those which are not inflammatory. It is far, however, from being an infallible sign. “The signs of the different alterations of which the kidney may be the seat are,” observes M. Bouillaud (*Journ. Compl.* xxxi. 13), “very obscure. All that semeiologists have said on this subject is far from being exactly conformable to observation. We may easily conceive why the diagnosis of affections of the kidney presents so many difficulties, if we reflect, 1*st*, that the depth at which that organ is situated withdraws it almost entirely from our means of exploration; 2*dly*, that the disturbance of its functions produces phenomena which may equally be occasioned by different diseases of the bladder and ureters; 3*dly*, that pain is not a constant accompaniment of renal affections. If we trusted to most pathologists, the most acute pains should be almost inseparable from inflammation of the kidneys. I do not pretend to deny that this may sometimes be the case, but I can affirm that I have met with incontestable traces of nephritis in persons who had not complained of any pain in the region of the kidneys. This absence of pain in the diseases of these organs is, besides, the more easily conceivable, that they are not sensible in the state of health. It may be added, that it is not very uncommon to observe violent pains in the region of the kidneys in persons who are not affected with any disease of these organs.”

No circumstance certainly tends more to perplex the medical observer, in attempting to determine, from the consideration of the symptoms that manifest themselves in individual cases, what the disease is which presents itself to his observation, than the great diversity which a disease may exhibit in its phenomena, according to a variety of circumstances not at all times easily appreciable; such as atmospheric influence, individual constitution, or, perhaps, mode of treatment. Those diseases that arise from the action of a contagious principle afford us the best opportunity of noticing the great diversities of appearance which the same disease may exhibit in particular epidemics, and as modified by diversity of constitution, mode of treatment, &c. If we compare, for example, the severest and the mildest case of typhus fever, or of smallpox, or scarlet fever, we shall have difficulty in believing that they are instances of the same diseases. Yet, in examining a considerable number of cases of any one of these diseases, we shall be satisfied, that between these extreme points there is a series of intermediate links which exhibit the most gradual transition from the most mild to the most severe.

In the diseases to which we have just alluded, we are unable to detect after death, when it occurs, any structural morbid conditions of the different textures, systems, and organs of the body, as being constantly and necessarily present, so as to justify us in regarding them as the proximate cause of the symptoms that manifest themselves; and this circumstance must no doubt add considerably to our difficulty in determining what are the essential and characteristic symptoms by which we should be able to recognise these diseases under the great diversity of appearances which they present in particular cases. But even in diseases in which we meet with structural alterations on examination after death, and these too having proceeded, in some cases, to a very considerable extent, we often find that there had been great diversity in the groups or trains of symptoms by which, in different individuals, the same structural change had been attended.

The various affections to which the contents of the cavity of the cranium are subject, furnish numerous illustrations of the fact that the same structural morbid condition may be attended in different cases by different groups or trains of symptoms. M. Andral, in his *Resumé* (*Malad. de l'Encephale*, p. 522) of the cases which he has published illustrative of softening of the hemispheres of the brain, observes, "In showing us the softening of the brain under all its forms, both anatomical and symptomatical, the preceding cases have shown us also how far the diagnosis of this affection is from being in all instances easy." "In each of the cases, it is not only that the symptoms are not the same, but that the same symptoms are combined, or succeed each other in the most different ways. Hence there result for one particular anatomical lesion, several forms of disease, which, in a nosological table, might be placed at a great distance from one another. In some cases the nosological disease is what is called an attack of apoplexy, with or without loss of consciousness; in others, it is a so-called ataxic or malignant fever; and in others, again, it is a gradual diminution either of motion only, or of intellect and motion at the same time." To the same purpose Dr Abercrombie remarks, that "when we endeavour to trace the leading symptoms connected with the different forms of organic diseases of the brain (comprehending under that name permanent changes of the cerebral substance itself, and new formations within the head), we do not find any uniformity, by which particular symptoms can be distinctly referred to the various forms of the morbid affections." He afterwards alludes to the extreme difficulty of fixing upon any general principles, or of referring the particular character of the symptoms to any thing in the seat or nature of the disease. "Tumours, for example, will be found, in one class of cases, unaccompanied by any remarkable symptoms; while, in other cases, tumours in the same situation, and of no larger size, are accompanied by blindness, convulsions, or paralysis. It does not appear that these diversities depend either upon the size of the tumours, or, as far as we know at present, upon their particular structure. But these points remain to be investigated; particularly what diversity of symptoms is connected with the nature of the tumours, and especially with their characters, as being tumours distinct from the cerebral mass, or as being indurations of the substance of the brain itself." (On Diseases of the Brain, third edit. p. 316, 322–3.)

Thoracic diseases.

In the viscera of the chest, as well as in those of the head, examples are to be met with of the same structural morbid condition giving rise, in different persons, to different combinations of symptoms in concourse and succession. Thus, Dr Latham, in illustrating his observation, that one of the common difficulties attending the diagnosis of pericarditis is referrible to the variableness of its own symptoms, remarks (Lond. Med. Gazette, iii. 211): "Disease belongs most unequivocally to the heart when pain is immediately referred to it, and when its action is disturbed. And when there is fever withal, it bespeaks the essence of the disease to be inflammatory, and fixes it, almost to a certainty, in the pericardium. But why in the pericardium more than in other parts of the heart? Because it is matter of experience, that, above all others, the pericardium is liable to acute inflammation in an incalculable proportion. But, strange to say, the pericardium may be acutely inflamed, and yet there may be no pain. And the disturbance of the heart's action is so little of one kind in all cases of pericarditis, that no certain mode of disturbance can be relied upon as a diagnostic symptom; and though fever may be present wherever there is pericarditis, there is often, at the same time, inflammation of some other organ, out of which it may arise."

Abdominal diseases.

Nor are the viscera of the abdomen more constant in respect of the symptoms by which their several structural pathological conditions are attended, than those of the head and chest. Dr Coe, after describing the ordinary signs of biliary concretions when they are making their way through the ducts, remarks (lib. supra cit. pp. 145–6, 147–8) that these "do not happen precisely alike in all persons, but will be found to vary in different patients, and even in the same person at different times, as well as to the number of the symptoms as the degrees of them, and the order in which they come on. Which variations," he continues, "will arise from several causes (in like manner as we see happens in other diseases), according to the difference of constitutions and other circumstances, and according to the size and shape, and perhaps other properties, of the calculi, as also of the ducts through which they pass. From which variation of the symptoms there sometimes arises an obscurity and uncertainty in judging of particular cases. So that we may have good reason to suspect that the disorder is occasioned by a stone, though we cannot be clear enough to pronounce that it is so; which at other times we can do with sufficient certainty." "As in the more uncommon and less known diseases, some particular cases may be so strong and clear as to be sufficiently obvious, so in some of the most evident diseases, which are readily known at first view when the train of symptoms is regular and uniform, we sometimes meet with so great irregularity, and such a perplexed combination of circumstances, that we are at a loss to unravel them, and find some difficulty in determining the particular nature of the case."

From the illustrations that have been given of the two last-mentioned sources of difficulty and fallacy in diagnosis, it must be obvious that, in practice, they frequently

Sources II. and III. may occur combined.

occur combined with one another. A concourse of symptoms which we shall designate as A, may arise from two different lesions *y* and *z*; whilst at the same time the lesion *y*, besides giving rise in one individual or class of individuals to the train of symptoms A, may in another individual give rise to a different train B. When, therefore, A presents itself to our notice, we may suppose it to depend on *y* in cases in which it actually depends on *z*. And when B presents itself to our notice, we may fail to detect its dependence on *y*, from its not occurring to us that this lesion can exist without being attended by the symptoms A. "If inflammation of the contents of the cranium always announced itself by the same symptoms," says M. Charpentier, "or if the symptoms by which it usually announces itself did not sometimes depend solely upon simple irritation reflected upon the brain by some organ or organic texture in a state of inflammation, its diagnosis would never be very difficult. This, however, is not the case, for inflammation of these parts occasionally differs so much from its ordinary physiognomy, both in respect of its course and of its symptoms, that the opening of the dead body can alone reveal its existence; whilst at other times simple sympathetic irritation of the brain deceives so much by the perfect resemblance of its symptoms to those which meningo-cephalitis (inflammation of the membranes and substance of the brain) presents, that the sight of the uninflamed condition of these parts can alone undeceive us as to the nature of the disease. Among the number of affections capable of inducing cerebral symptoms which by their concurrence simulate meningo-cephalitis, we must particularly reckon the presence of worms in the intestines, dentition, pneumonia at its height, but, above all, inflammations of the stomach and small intestines." (*De la Nature*, &c. *de la Maladie dite Hydrocéphale Aiguë*, Paris, 1829, p. 195.) M. Rostan, in showing that pain, vomiting, and swelling form the principal characters of cancer of the stomach, remarks (*Médecine Clinique*, ii. 477), "These symptoms, however, may exist, and the disease (that is, the pathological condition of cancer of the stomach) not exist, and *vice versa*, that is to say, the symptoms may be absent, and yet the disease exist. And, in the *first* place, pain appertains to all diseases of the stomach, and cannot be regarded as a special sign of that in question; the same may be said of vomiting; and, lastly, swelling may appertain to a multitude of different lesions. Engorgement of the liver, of the spleen, or of the pancreas, the accumulation of fecal matters in the arch of the colon, aneurismal dilatation of the aorta, and other accidental tumours, may so much the more readily pass for cancer of the stomach, that most of them occasion disturbance of the digestive functions. In the *second* place, the pain may not exist, as happens in cases of indolent cancer, which, as is well known, are not uncommon. The vomiting, also, may not occur, 1*st*, when the pylorus is free; 2*d*, when it is extensively ulcerated; 3*d*, when the whole of the stomach is involved in the disorganization. The swelling may not be sensible, which, so far as regards diagnosis, is the same as if it did not exist, 1*st*, when the false ribs and sternum descend very low, and cover it; 2*d*, when the free border of the liver lies over it; 3*d*, when the subject is pretty stout; 4*th*, when the abdominal muscles contract," &c. "Notwithstanding these difficulties," adds M. Rostan, "it is in general possible to arrive at a precise diagnosis, because it rarely happens that they occur in sufficient number entirely to mask the disease."

Precautions in their application.

But although a train of symptoms apparently identical may arise from different morbid lesions, and different trains of symptoms may arise from what appears to be an identical lesion, it is possible that in neither case does there actually exist the identity supposed. For, notwithstanding the apparent resemblance of the symptoms arising from different lesions, it seems reasonable to suspect that there may exist points of difference between these symptoms, if we were capable of detecting them. And, accordingly, the progress of improvement in diagnosis has in numerous instances brought to light symptoms or marks by which we are enabled to distinguish between different morbid lesions of the economy, that had previously been supposed to produce precisely the same trains of symptoms.

Of many nosological diseases, such as asthma, ileus, and jaundice, it may be said that they afford examples of the same group or train of symptoms, arising from different pathological conditions. Asthma, for instance, understanding by that term "difficulty of breathing returning at intervals, with a sense of oppression in the chest and sibilous respiration, cough difficult at the commencement of the paroxysm, or absent, towards the termination free, with mucous expectoration, frequently copious," may proceed from diseases of the respiratory organs, or of the heart and large vessels, or of the organs belonging to the nervous system. But though on a first view it may appear true in respect of each of the nosological diseases that has been mentioned, and of many others that might be enumerated, that different lesions give rise to the same group or train of symptoms, on more accurate examination it will generally be found possible to detect, in the cases which depend on one pathological condition, symptoms that are absent in the cases which depend upon a different pathological condition; or, though the symptoms of the two sets of cases are the same in their general nature, one or more of them may be found to be differently modified. "We must at all times," observes M. Dalmas, "conform to that rule of logic which teaches that one same effect always results from one same cause. If, in cases which have exhibited the same symptoms during life, we meet, after death, with different lesions, we may be sure that the true seat of the disease has escaped our researches. It is proper to remark here, however, that there are some vague words employed in symptomatology to express general results, for which it would be unjust to pretend that, in conformity with the rule alluded to, we ought always to find a single and identical lesion. The words dyspnœa and palsy are so circumstanced. If there be twenty species of dyspnœa, we need not be astonished if we find as many different lesions capable of producing it." It is upon such diversities in the minor features of particular sets of cases, depending on differences of pathological condition, that nosologists found, or should found, their *varieties* of diseases; and it is by the accurate marking of these diversities that they should seek to improve their systems of definitions.

In like manner, it seems probable, that when different groups or trains of symptoms arise from what appears to be the same morbid lesion, there is in reality some unperceived diversity in the lesion. It may be identical in respect of its nature in the different cases, but different in its seat or in its relations to other parts. For, supposing that in two or more cases the same organ is affected with the same form of disease, it is obvious that there may be considerable difference in the functional disturbance, and consequently in the symptoms that arise, according to the particular part of the organ in which the pathological condition may be seated. In cases of cancer of the stomach, for example, the symptoms vary greatly according as one or other aperture, or the body of the stomach, are affected separately, or in conjunction with one another.

In illustration of the remark, that where the same lesion appears to give rise to different symptoms, there may actually be some difference in the relation of the lesion to other parts, though not adverted to by a superficial observer, we may quote an observation made by M. Cruveilhier in reference to cancerous tumours in the brain. (*Anatomie Pa-*

thologique, folio.) "A point extremely important in the history of these tumours," says he, "is the difference of the effects produced by causes apparently identical. Thus, in one individual, hemiplegia is occasioned by a spheroidal tumour of two inches in diameter, while in another a tumour of four inches may exist upon the brain without any paralysis being induced, though everything is in other respects correspondent as regards the seat and nature of the disease. I think," adds this intelligent author, "that one of the circumstances to which this diversity of result is attributable is the difference of the direction in which the compressing power acts."

M. Lallemand has with much justice observed, in the preface to his work on Diseases of the Brain (p. xvi.), that "The circumstance which has most influence on the concourse of symptoms, is the more or less rapid, the more or less slow course of the disease. This influence is such as to cause that very different pathological alterations manifest themselves by phenomena sufficiently similar to deceive the most attentive observer, simply from their corresponding in their general course or progress. Thus, for example, there is more resemblance between the symptoms of an acute inflammation of the brain, and of a softening of the cerebral substance, and those of an apoplexy, or sudden compression of the brain, whatever be its cause, than between the symptoms of an acute inflammation and those of a chronic inflammation of this organ. In the same way, an encysted abscess has less resemblance, in respect of the external phenomena which it produces, to a recent abscess, than to a scrofulous, fibrous, bony, or hydatid tumour, or a foreign body lodged in the brain. The same," he adds, "may be said of the affections of the arachnoid membrane."

"Reason and common sense," observes Dr Latham, "seem to declare, that there cannot be the same disease of the same organ, and yet the most prominent symptoms be absolutely different. But morbid anatomy is not content merely to contemplate a disease in its general character, and have done with it: it takes into account also the various morbid products and changes of structure accompanying it, or resulting from it. In pericarditis it takes cognizance of the lymph deposited upon the surface, and of the fluid effused into the cavity of the pericardium; the different quantities of each in different cases, and the different proportions which they bear to each other. It notices, also, that the lymph sometimes contracts a partial and sometimes a complete adhesion, and sometimes none at all; that the fluid is sometimes freely effused into the pericardium, and envelopes the whole heart; and is sometimes limited by adhesions to a part of it. These conditions must influence the action of the heart in various ways; and morbid anatomy, knowing these things, suggests to clinical observation, with respect to pericarditis, that as its products are different, so too must its symptoms be in different cases, and even in the same case at different periods." (Lond. Med. Gaz. iii. 212.) These observations are well calculated to excite the most minute attention, on the part of medical observers, to the less obvious differences in individual symptoms or groups of symptoms produced by different lesions, and to the less obvious differences in particular lesions which seem to give rise to different symptoms or groups of symptoms.

V. m- licat s f les s

The last source of difficulty and fallacy which we have to notice as occurring to the medical practitioner, in attempting to judge, from the symptoms that manifest themselves in any particular case, as to the seat and nature of the disease with which his patient is affected, arises from the circumstance, that two or more parts may be the seats of morbid conditions in the same individual at the same time, whether these morbid conditions shall correspond or differ in their nature, and whether they shall have come on simultaneously or in succession. Such a complication of pathological conditions will possibly produce a complication of symptoms which may render it very difficult for the practitioner to ascertain how many parts are disordered, where the principal seat of disorder is, what part was primarily affected, and how far the disorders in the others depend upon that of the part first affected. Thus, if we suppose an individual to be labouring at the same time under the symptoms of disorder of the stomach and of disorder of the heart, the practitioner may experience considerable difficulty in determining whether the symptoms of deranged digestion and those of disordered circulation are referrible to two distinct primary morbid conditions, or whether one or other of these groups of symptoms is not produced sympathetically; whether, whilst one of the groups arises directly from a primary morbid condition of the corresponding organ, as those of indigestion from disease of the stomach, the other group of symptoms, those of disordered circulation, may not depend on sympathy of the heart with the stomach, rather than on a primary morbid condition of the heart itself.

producing complications of symptoms difficult to unravel;

In the case just supposed, the co-existence of two distinct pathological conditions in the economy is obviously accidental, there being no necessary bond of connection between them. But in other instances, from the dependency of different organs and functions upon one another, the existence of diseased action in one organ may occasion diseased action (whether of a simply dynamical or of an organic character) in another. Thus, it is now well established, that in a large proportion of cases of disease of the heart, the change of structure or of action which this organ undergoes is occasioned by an interruption to the circulation of the blood through some other organ of the body, as, for example, through the lungs, in consequence of previous disease of these viscera. Hence, in the progress of cases of this kind, the symptoms belonging to the organ in which the impediment to the circulation exists, come to be complicated with those immediately referrible to the altered condition of the heart, occasioned by that impediment.

The reciprocal dependency of the stomach and liver on one another furnishes us with another example of complication of morbid lesions producing complication of symptoms. "It must be admitted," says Dr Cheyne (Cases of Apoplexy, &c. Lond. 1812, p. 171), "that it is often difficult to know to which viscus of the abdomen we ought to refer the uneasy sensations that attend imperfect digestion. When disease of structure is apparently confined to the liver, the patient has been known to suffer greatly from dyspeptic symptoms (that is, symptoms of derangement of stomach)—great anxiety, sickness, flatulence, and prostration. And, on the contrary, when the stomach alone appears to be the seat of disease, there is not unfrequently an imperfect or redundant secretion of bile (indicating derangement in the action of the liver), with listlessness, depraved sensation, tædium vitæ, &c. The work of the stomach is never well performed unless when the liver is sound, and the functions of the liver equally require a healthy condition of the stomach. As when either viscus is in a diseased state, the uneasy sensations felt in consequence are referrible to both, the stomach and liver are to be considered, in their morbid states, as firmly linked as in health. But in practice it is of consequence to discover in which organ disease has begun; for, if we are able to restore the organ primarily affected, the organs sympathetically drawn into disease will often return to a healthy state in consequence."

The supervention of a new morbid condition in a person previously labouring under some complaint, whether in the same or in a neighbouring organ, is very liable to be overlooked till it has made considerable progress, in consequence of the premonitory and early symptoms being suffocated, as it were, in those of the original malady. And if in a case in which there exist two or more distinct pathological conditions at the time of the physician's examination, the morbid phenomena or symptoms produced by one of them be, from the nature or the seat of the organ affected, much more apparent than those produced by the other, then it may very readily happen that the practitioner, having satisfied himself of the existence of the more considerable pathological condition, may take it for granted that this is in itself sufficient to explain all the phenomena that present themselves, and thus fail to detect the existence of the other pathological condition, upon which the less marked, though perhaps not the least important, portion of the symptoms actually depends.

or modifying or obscuring one another.

But it is not the mere circumstance of complication, and the difficulty of separating the symptoms arising out of different co-existing pathological conditions, into their respective groups, that render cases of this kind puzzling and perplexing to the practitioner. It frequently happens that the symptoms of one or other, or possibly even of both, the co-existing pathological conditions, are modified in such a degree as to throw over them a great degree of obscurity. "In many diseases," says M. Melier (*sur le Diagnostique*), "instead of a single organ, or of a single texture, there are two, or a still greater number, affected. It rarely happens, for example, that a mucous membrane is alone affected; it is the same with the skin. It is necessary to attend to this coincidence of several diseases, or rather of several organic foci of disease; for in almost all cases the physiognomy of the symptoms is thereby changed. Two diseases existing in this way together, are far from proceeding as if they existed separately. On the contrary, they modify one another. Sometimes they mutually diminish one another's intensity; at other times one of them, in running through its stages, preserves a preponderating intensity, whilst the other, restrained, so to speak, in its development, advances slowly. The first only attracts attention; but when once it has terminated, the second, which, up to that time, had been slight or unperceived, is awakened, and excites fresh symptoms, which the existence of the other seems to have prevented; as if there were in our economy, as Bichat said on this subject, only a certain amount of strength which cannot exist in excess in one place without being diminished in another, and that nature does not indulge in the development of several diseases at the same time."

"It rarely happens," observes M. Lallemand (p. xix. xx.), "that a patient dies of a simple and single affection. In almost all cases, several organs have been involved simultaneously or successively. Then the symptoms of the one or the other disease predominate; the others are very obscure; and, in all cases, these complications influence one another reciprocally, so as to give an unusual aspect to the concourse of symptoms, and to the progress of the diseases. Formerly, in the examination of dead bodies, attention was paid only to the organ which was supposed to be diseased; and when the alterations did not correspond exactly to the symptoms, medical men were contented with regarding the fact as anomalous; or they supposed they had explained it by attributing it to a peculiar idiosyncrasy; or, better still, they made an abstract being of it, existing by itself, and called it an essential disease. The progress of the different parts of medicine, the exactness that is now bestowed upon the observation of symptoms, and the attention that is given to the examination of dead bodies, enables us to appreciate more accurately than was possible till recent times, the influence of each of these complications on the course and concourse of the symptoms."

In some instances the co-existing pathological conditions, each of which furnishes its particular symptoms to the resulting concourse, are seated in the same organ, or in textures immediately adjacent; as in the investing membranes of parenchymatous organs. "Next to those diseases of the brain," observes M. Rostan (*Méd. Clin.* ii. 355–6), "which do not exhibit any symptom, or what are called latent diseases, there are none more obscure than those which are complicated with one another. Thus, when there exist at the same time several different alterations of the brain, as hæmorrhage and primary or consecutive softening, it is almost impossible accurately to determine the nature of the affection; but as in general we recognise at least one of the alterations, these cases cannot rigorously be regarded as errors." M. Lallemand, in remarking that the pathological alterations of the brain are not always accompanied with the same symptoms, and in pointing out that "this apparent disagreement depends sometimes on the different seat of the affection, sometimes on the age, on the sex, or on the temperament of the patient; sometimes on important complications; and, lastly, at other times on the acute or chronic course of the disease;" adds, "when we compare together cases of affection of the brain and of the arachnoid membrane, exempt as much as possible from complication, we see that they exhibit symptoms very distinct, a particular character (*cachet*); whilst those cases that are complicated, as is most frequently the case, present a mixture of the two orders of symptoms, a circumstance which has not been sufficiently attended to, and which has frequently led observers into error." (Preface, p. xvi.) The same observation has been specially applied by Professor Van Coetsem to the complication of one particular form of cerebral disease, viz. softening, with inflammation of the arachnoid or serous membrane of the brain. "One of the causes," says this author (lib. cit. p. 374), "which seems to us to render the diagnosis of cerebral softening so obscure, is the complication of arachnitis (inflammation of the serous membrane of the brain), sometimes of an acute and sometimes of a chronic character, which frequently accompanies or precedes the morbid degeneration of the substance of the encephalon, and in other instances succeeds to it. In fact, it has more than once happened to us, after conceiving that we had recognised the nature and the seat of the disease by its symptoms, to find in the bodies of those who have died, independently of the lesion of the substance of the brain, which we expected, unequivocal traces of inflammation of the serous membrane that surrounds this viscus, such as adhesion between the different laminæ of the arachnoid, sero-purulent effusion into the lateral ventricles, &c. In such circumstances the *facies morbi* appears to us very doubtful, in respect of diagnosis, because the symptoms connected with each of the co-existing affections are far from being characteristic."

In other instances the different pathological conditions which exist simultaneously have their seats in distant organs. When one of these organs is the brain, the symptoms that might be expected to arise from the diseased condition of the other organ are exceedingly liable to be obscured. "The diseases of the brain," says M. Bourdon (*Principes de Physiologie Médicale*, i. 164), mask the diseases of other organs. Far from requiring opium, cerebral affections serve as such to the whole body." M. Lallemand, in speaking of the influence of cerebral affections on the development of the symptoms of such diseases as may exist simultaneously with them, observes (i. 233), "Whenever the functions of the brain are disturbed, and there exists at the same time an inflammation in some other organ, the pain produced by that inflammation diminishes, and even entirely disappears." "It is not," he adds, "because the pain of the head is greater, that that of the abdomen or of the chest, &c. disappears, for frequently there is no headach in these cases. Nor is it because the inflammation in the brain is more severe, seeing that an effusion of serum or blood may produce the same effect; it is because the pain being the result of a sensation perceived by the brain, whatever deranges its functions will cause this symptom of the inflammation to disappear. But if the inflammation is severe, it is not arrested in its development by the cerebral affection; all the other phenomena continue, because they are not, like the sensibility, dependent on the brain. The disease runs through its course in a manner so much the more dangerous, as it is the more difficult to be recognised, and produces the death which is attributed to the affection of the brain, though this be in reality only accessory. If the body be opened with some attention, we are surprised to find so little relation between the symptoms observed during life and the morbid alterations found after death; and this misapprehension throws discredit on medicine, and on pathological anatomy in particular. It is, therefore, of the greatest importance, whenever we observe any symptom which indicates an alteration in the functions of the brain, not to allow ourselves to be imposed upon by the absence of pain. We must then investigate with so much the greater attention the other phenomena, which, being independent of sensibility and volition, do not vary with the state of the brain." "These proper symptoms are so much the more precious, that, if alterations of the brain mask, so to speak, certain inflammations of the stomach, by causing the disappearance of the pain, it also happens very frequently, by a singular sort of compensation, as it were, that certain cerebral affections produce sympathetically nausea and obstinate vomiting, which might be regarded as symptoms of inflammation of the stomach." "These considerations on the perception of pain apply to all inflammations complicated with cerebral affection."

The influence of delirium in concealing the symptoms of diseases seated in other organs than the brain must be explained upon the same principles. In reference to a case of fever in which, as appeared on examination after death, there occurred perforation of the small intestine, followed by inflammation of the serous membrane of the abdomen, but in which the usual symptoms of these morbid conditions did not manifest themselves, M. Louis takes occasion to observe, that "the most formidable symptoms are usually so completely masked by delirium, that as soon as it declares itself, the diagnosis of diseases that are most easily recognised becomes difficult, and sometimes even impossible." (*Recherches Anatom. Pathologiques*, p. 187.)

In treating of "ramollissement (softening) of the central parts of the brain, combined with serous effusion," Dr Abercrombie remarks, "an interesting modification of this affection is that which supervenes upon other diseases, chiefly of a chronic nature, especially affections of the lungs; and the remarkable circumstance in these cases is, that the pectoral symptoms generally cease after the commencement of the symptoms in the head." (On the Brain, 3d edit. p. 137.)

M. Andral, in speaking of the varieties of pneumonia, or inflammation of the substance of the lungs, observes (*Malad. de Poitrine*, i. 369), that some very important modifications of this disease depend on the absence of one or of several of its usual symptoms, whence results latent pneumonia. "It is well established," he continues, "that an intense inflammation of the parenchyma of the lungs may exist without being announced by dyspnœa, cough, or expectoration. It may sometimes happen, even, that at the same time that these symptoms are wanting, auscultation and percussion themselves cease to reveal the true state of the lung; in this case it becomes impossible to establish a diagnosis. We have already remarked that these latent pneumoniæ are rarely primary, but generally supervene when an inflammation of the lung complicates some other disease." "We have seen," remarks the same author (*Fievres*, p. 441), "in recapitulating the lesions discovered by opening the bodies of the dead, that in severe fevers pneumonia was a very frequent complication, and most frequently a fatal one. If we pass in review the symptoms which have announced this inflammatory affection, we shall find that, in most of the cases, the diagnosis has been very obscure. These intercurrent pneumonic affections have frequently not been announced by any apparent oppression of respiration, nor by any characteristic expectoration. The cough itself was very slight, and the disorganization of the lung might be completed before even any suspicion of the existence of pulmonary inflammation was excited. Hence the indispensable necessity of frequently practising percussion and auscultation in such cases. Lastly, we have seen these two modes of investigation become themselves useless, when the inflammation was settled in the centre, the base, or roots, of the lungs. The absence of all characteristic expectoration in these cases of intercurrent pneumonia may often depend on the circumstance that the patients, having reached the last degree of debility, swallow their expectoration, when they have no longer the strength or instinct to spit it out. But sometimes also it appears that there is really no secretion, and this seems to occur particularly in cases of splenisation, or pultaceous softening of the lungs."

Recapitulation.

We have thus endeavoured to illustrate the various circumstances under which it may happen that, in the examination of a patient, a well-informed medical practitioner may fail to detect the existence of any morbid or pathological condition of the economy, though such a condition actually exists; or, in recognising the existence of some such condition, may form an incorrect judgment respecting its nature or its seat. These sources of error in diagnosis we have attempted to reduce to four general heads, which may be shortly stated in the following terms: 1*st*, Morbid lesions without symptoms; 2*d*, identical symptoms with different lesions; 3*d*, different symptoms with identical lesions; and, 4*th*, complications of lesions and symptoms.

We have seen, in the *first* place, that many changes may take place in the structure of the different textures, systems, and organs of the body, and that even to a considerable degree, without producing any symptoms which attract the notice of the individual himself, or of his medical attendant, in the event of some other ailment giving occasion to the latter to inquire into his patient's state of health; or, at all events, without producing any symptoms calculated to direct attention to the organ or part in which the change has occurred. The causes that may be assigned for this occasional latency of morbid lesions we have endeavoured to refer to the following heads: 1*st*, The lesion being seated in an organ the function of which is not exercised in a conspicuous manner; 2*d*, its being seated in an organ, of the function performed by which we are ignorant; 3*d*, its being seated in an organ that is not essential to the wellbeing of the economy, or that is of trivial importance; 4*th*, the exercise of the function not being prevented by the change that has taken place in the structure of the organ, as happens particularly when the alteration is slow in its progress; and, 5*th*, some other organ exercising the function or supplying the place of that which is injured. We found it necessary to admit, also, that in some instances no explanation of the latency of the morbid lesion can be given; and we may remark, that in explaining the same particular instance of latency, we may sometimes find it necessary to refer it to two or more of the causes which we have mentioned, operating in conjunction.

We have seen, in the *second* place, that a particular, and, to all appearance, identical group or train of symptoms, which in one individual is connected with one form of pathological condition, may, in another individual, be connected with a pathological condition of an entirely different nature. We have seen, that when different pathological conditions or proximate causes give rise to the same group or train of symptoms in different persons, these lesions may be both organic, or the one lesion may be organic and the other dynamical. In some instances the different lesions giving rise to the same group or train of symptoms have their seats in the same organ; in other instances they are seated in different organs or parts of the body, and these different organs or parts may be related to one another simply in the way of contiguity or superposition, or there may exist functional dependencies or sympathetic connections between them. To this head we have referred the class of cases in which lesions of the central portions of the nervous system give rise to symptoms in particular organs of the body similar to those that are produced, or that may be supposed to be produced, by lesions of which these organs are themselves the immediate seats; and that other class of cases in which a central portion of the nervous system exhibits symptoms of being affected with some morbid condition, while in fact it is in some other organ that the primary source of disturbance is seated. We had occasion to observe, that in some of the cases in which one disease assumes the characters that usually appertain to another, it is a constitutional disease which assumes the appearance of a local one; and that in other instances, again, it is a local disease which assumes the semblance of one that is constitutional. Sometimes the simulating disease retains one constant character throughout its progress, while in other instances it assumes in succession a variety of different characters. We have seen that the characters by which certain specific diseases can be distinguished from analogous diseases that are destitute of a specific character, are often far from being obvious, and that consequently the discrimination of these two classes of diseases is frequently a matter of difficulty and uncertainty. We have seen, likewise, that in some cases the community of symptoms between two diseases may exist only during a particular period of their progress, as at their commencement or termination; and that in other cases the community of symptoms may continue during their whole progress.

In the *third* place, we have seen that different groups or trains of symptoms may arise, in different individuals, from pathological conditions or proximate causes that appear to be identical. This seems to occur whether the pathological state or lesion be simply dynamical or organic. We have seen that the diversity in the group or train of symptoms may be confined to one of the symptoms, or to a few only, or may extend to the greater part or to the whole of them; and that it may consist in the presence of a symptom or symptoms not usually attendant upon the morbid condition, or in the absence of a symptom or symptoms by which it is usually accompanied. Under this head we have illustrated, or rather suggested, the influence of external and internal circumstances in modifying the characters which the same disease exhibits in different persons.

In relation to these two last-mentioned sources of difficulty and fallacy in diagnosis, we have seen reason to suspect that when groups or trains of symptoms apparently identical arise from different morbid lesions, and different groups or trains of symptoms arise from what appears to be an identical lesion, it is possible that in neither case does there actually exist the identity supposed; but that the apparent identity is attributable only to our inaccurate observation, or to the imperfection of the means of investigation hitherto ascertained.

Fourth and *lastly*, we have seen that several different pathological conditions, having their seats in the same or contiguous organs or parts, or in organs or parts remote from one another, may exist in the economy simultaneously, whether they shall have come on simultaneously, or shall have followed one another in succession; and, in the latter case, whether they shall stand in the relation of cause and effect, or shall be entirely independent of one another; and that not only may these co-existing pathological conditions, in producing in a more or less marked manner their respective symptoms, give rise to a complication of phenomena which in many instances it is by no means easy to unravel, but they may in various ways modify and obscure the phenomena appertaining to one another.

In illustrating these several sources of difficulty and fallacy in diagnosis separately, it has very clearly appeared, that in a large number of cases they are met with, not singly, but more or fewer in conjunction; a circumstance which cannot fail seriously to increase the embarrassments of the practitioner. Had our space allowed of it, it was our wish, with a view to impress more forcibly on our readers the practical operation of these sources of difficulty in ascertaining and distinguishing diseases, to have traced their influence, separately or variously combined, in rendering difficult and obscure the diagnosis of some one particular disease. For that purpose we had made choice of pulmonary consumption; and it is on this account that, in illustrating the several sources of difficulty individually, we have not taken advantage of the numerous illustrations of these which consumption affords, and which have been so ably pointed out in the writings of Laennec, Andral, Louis, Abercrombie, Craigie, and Clark.

With this recapitulation we must bring to a close our review of the various sources from which those difficulties proceed that the medical practitioner has to encounter, either in detecting the presence of disease in the human economy, or, when its existence is manifestly proclaimed by obvious signs, in discriminating, in individual cases as they present themselves to his observation, the true nature and seat of the affection. To the professional reader, we flatter ourselves, such a review may be not without its use, as tending to bring before him, under somewhat of a systematic arrangement, a number of particular facts, of which, in order to avoid the risk of perpetual errors of diagnosis, it is necessary not only that he should be aware, but that he should be able, in the exercise of his art, readily to recall the recollection, and make the appropriate application. On the general reader, we venture to hope, a knowledge of the nature and extent of these difficulties may tend to impress, *first*, the importance of the friends and attendants of the sick, as well as the sick themselves, not only facilitating such inquiries as the medical practitioner may himself institute, but spontaneously affording every information from which it can be supposed that he may possibly derive aid in forming a judgment respecting the disease under which his patient labours; *secondly*, the inexpediency of urging the medical practitioner to the precipitate expression of an opinion respecting the nature of his patient's malady, which, however incorrect it may be, must, when once it has been pronounced, enlist upon its side both his pride and his interests, and thus render it difficult for him to perceive the true posture of affairs, and even more difficult for him, perhaps, to avow it when perceived; and, *thirdly*, the unreasonableness of withdrawing confidence from a practitioner of whose knowledge and skill they have had manifold personal experience, or sufficient warrant on the testimony of others, because in some particular case or cases the judgments which he has formed may have proved to be incorrect. It has been justly remarked, that "in the practice of physic, there is doubtless a great difference in men as to quickness of apprehension, and also as to the improvement derived from experience; so that one practitioner may discover a difficult case much sooner than another. But there is also a difference in respect of cases.

Some are obvious and easy to proper judges at first view; others are so obscure and perplexed that they are not to be hit off at first sight, nor to be discovered by a superficial inquiry, but require time and attention, with a careful discriminating examination of all the circumstances of the patient, before the true state of them can be determined. Some that are not knowable in their beginning, will become evident in their progress or maturity; and it must be owned there are some that will be too hard for all our inquiry and consideration, and cannot be fully discovered but by the anatomical knife after the death of the patient." (Dr Coe, lib. cit. p. 5, 6.)

As a knowledge of the existence of these difficulties seems calculated to bespeak from the public a more favourable consideration for the practitioner who has availed himself of all those means which medical science affords for improving his acquaintance with diseases and his means of discriminating them, so we cannot but think that there is another purpose to which it may, in some degree, also be subservient. We have already expressed our conviction (art. MEDICINE), that it is vain to trust to any legislative enactments for the suppression of quackery; and that the only mode in which any one can hope to promote this end, is by assisting in opening the eyes of the public to the grossness of the delusions which, in matters relating to medicine, they practise upon themselves, or allow others to practise upon them. But if it be admitted that a knowledge of the nature of the disease under which a patient labours, is an indispensable preliminary to the safe and proper management of his case; and if, in attempting to arrive at this knowledge, so many sources of difficulty and fallacy await even the best-informed medical practitioner,—him who is furnished with all the means of avoiding and overcoming them which the accumulated experience of ages has been able to discover or invent,—the prudent man may hesitate before he admits the belief that these difficulties can be overcome by persons of no scientific instruction, and who professedly reject all aid from the observations or experience of others; he may well pause to consider whether the discrimination of such a person can be with safety relied upon, even in those cases of which Dr Coe speaks as "obvious and easy to proper judges," far less in those obscure and perplexed cases, which require so much skilled observation "before the true state of them can be determined;" and whether the freedom of such a person, from doubt or uncertainty in diagnosis, may not arise from the rash presumptuousness of ignorance, rather than from the reasonable confidence which knowledge is calculated to inspire.

We could have wished, before terminating this article, to have taken a view of the means by which the medical practitioner endeavours to overcome those difficulties, and avoid those fallacies of diagnosis, which we have represented as arising from the uncertain relations that subsist between internal morbid conditions of the economy and their external manifestations or symptoms. The observations we can offer on this subject must necessarily be very brief and imperfect; but we are unwilling to leave on the minds of our readers the impression that medical science has accomplished, and can be expected to accomplish, nothing towards the more accurate determination and marking of these relations, which can aid the practitioner in his diagnostic judgments.

Previously to entering on these observations, however, we would repeat, what we have already hinted, that diligence in seeking out, and precision in examining, the *symptoms* of diseases, are often of themselves sufficient for the correction of those errors into which a less diligent investigation and less precise examination of these phenomena would be liable to lead the practitioner. "There is probably," as Mr Hunter has remarked in his work on the Venereal Disease, p. 379, "no one disease to which some other may not bear a strong resemblance in some of its appearances or symptoms, whereby they may be mistaken for each other. But diseases which resemble others seldom do it in more than one or two of the symptoms; therefore, whenever the nature of the disease is suspected, the whole of the symptoms should be well investigated, to see whether it agrees in all of them with the disease it is suspected to be, or only in part." The judicious remarks applied by Dr Southwood Smith to the symptoms which, in the progress of fever, indicate the occurrence of morbid changes within the abdomen, are applicable, probably, to many other cases of disease. "Their great peculiarity," says he, "which it is as important to know as it is to understand their indication itself, is their want of prominence. They are always to be discerned, or with extremely rare exceptions; but they seldom or never force themselves upon the notice of the careless, or extort the attention of the unobserving: still they are not the less constant in their occurrence because they come without noise, nor is the indication they give of their presence less significant because it is unobtrusive." (P. 288.)

Some physicians, indeed, as we had elsewhere occasion to remark (MEDICINE), have been so much impressed with the fallacies to which those judgments are exposed which medical men form respecting the nature of diseases, from a consideration of their symptoms, that they have gone the length of representing symptoms as of no assistance in diagnosis. "It is not, then, on the symptoms," says a late French writer, "that the diagnosis of diseases must be founded. In order to recognise them, we must go farther back, to their source, and discover the internal and concealed spring which has been the *primum mobile* of the derangements that appear externally. We must investigate the organic lesion which has produced, which keeps up, and renews the symptoms observed. It is this lesion which constitutes the disease; it is it which has induced the disturbance of the functions." "In diagnosis," says the same author, "we must absolutely direct our attention to the organs, and in no degree to the symptoms." Of the propriety of endeavouring to arrive at a knowledge of the pathological state, morbid condition, or proximate cause on which a disease or particular case of disease depends, and of the curative efforts of the practitioner being directed against that pathological condition when it can be ascertained, and not against one or other of the various symptoms to which it gives rise, no doubt can be entertained; but it must never be forgotten, that it is only by an attentive investigation of the symptoms that we can hope during life to arrive at a knowledge of the pathological condition which exists. And it would be easy to adduce, from the same author who speaks of excluding symptoms from our attention in diagnosis, passages fully displaying the incorrectness of these views, or rather showing that the expressions in which they are clothed greatly belie the meaning they were intended to convey. To escape the fallacies into which symptoms are apt to lead us in our conclusions respecting the pathological conditions upon which they depend, we must study them in all their varieties of appearances and combinations. The doctrine of symptoms is in every respect as improvable as any other department of medical science. By the successive labours of medical men, additions are constantly making to the number of symptoms or indications by which we are enabled to arrive at a knowledge of the existence of disease, and of its particular nature and seat. And with regard to those symptoms that have been long familiar to medical practitioners, and constantly employed in characterizing and discriminating diseases, much has been done, and much is doing, in the way of determining more accurately their connection with particular pathological conditions of the economy; so that not only are the means which medical men possess of discriminating diseases, through the medium of symptoms, becoming gradually more numerous, but they are also becoming more valuable.

But when the symptoms actually present are insufficient to guide the practitioner to a satisfactory judgment respecting the nature of the disease before him, are there any subsidiary aids towards the accomplishment of this object, of which he may avail himself?

Previous history of the case.

In the first place, a careful consideration of the previous history of the case, from the earliest development of morbid phenomena to the period of examination, may often afford important assistance. For even in cases in which there exists a striking coincidence between the symptoms produced by two distinct lesions at a particular stage of the progress of one or other of them, there may be such differences either in the concourse of their symptoms at other periods, or in their general course, as to enable the practitioner who is duly informed respecting these particulars to decide on which of the lesions the case under his immediate observation depends.

Causes producing it.

In the second place, when, after the most careful consideration of the symptoms as they actually exist, and of the course which the disease has run previous to the time of examination, the nature of the malady is still doubtful, the practitioner may in some instances be assisted in its determination by the knowledge he obtains of the causes by which it has seemed to be induced.

Effects of remedies.

In the third place, it happens in some cases that the first certainty the practitioner acquires respecting the nature of the disease with which he has to deal, is from the effects of the remedies administered for its removal; whether these effects shall be such as to confirm him in the correctness of the opinion upon which his mode of practice has been founded, or to satisfy him of the error of his diagnosis. It must not be forgotten, however, that inferences of this kind must be subject to the numerous fallacies to which the judgments of medical men, respecting the influence of remedies over diseases, are exposed. Thus, it is well known that medical men long imagined that the most certain test of a syphilitic or non-syphilitic taint in particular cases was to be derived from the fact whether or not the malady disappeared when no mercury was employed; an opinion which recent experience has shown to be wholly without foundation. In modern times Italian physicians have established, as a general law in pathology, a principle, which they designate the law of tolerance of medicines, that would, if well established, render a knowledge of the *juvantia* and *lædentia* a very powerful assistance in forming our diagnosis, and particularly in judging of the intensity of a disease. The principle to which we allude is, that the human body, in becoming diseased, acquires the faculty of supporting medicines suited to its state, in doses exactly proportional to the intensity of the disease; and that it loses this faculty in proportion as the disease diminishes, and in the ratio of its diminution.

It has generally been understood, that when there existed a doubt as to the inflammatory or non-inflammatory character of a disease, a cautious trial of blood-letting might advantageously be made, with a view to throw light on the nature of the disease, and to determine the proper mode of treatment to be pursued. "The effects of remedies carefully considered," says Dr Marshall Hall, "throw an important ray of light upon the nature and force of the disease, and upon the condition and energies of the system." (i. 1.) And in reference to this proposition the author observes, "One of the sources of diagnosis enumerated constitutes a department of knowledge which may be termed *new:* it is that of the effect of remedies, and especially of blood-letting, as a diagnostic of diseases, and as a criterion of the general powers of the system. In cases in which it is doubtful whether the pain or other local affection be the effect of inflammation or of irritation, the question is immediately determined by placing the patient upright, and bleeding to incipient syncope: in inflammation much blood flows; in irritation, very little. The violence of the disease, the powers of the system, and the due measure of the remedy, are determined at the same time. There is, in my opinion," adds Dr Marshall Hall, "no single fact in physic of equal importance and value in the diagnosis of acute diseases and the use of an important remedy." (P. 2, 3.) How far this application of the Italian doctrine of tolerance of medicines to the practice of blood-letting affords a safe rule of practice, we cannot here inquire; but we may observe, that common opinion assigns more influence in the production of syncope from venesection to individual constitution, than to the nature or intensity of the disease for which it is practised.

Impro- ments diagn- resulti from tholog anatom

Lastly, when a case, respecting the exact nature of which any doubt has existed, proves fatal, it is of great importance that the practitioner should have an opportunity of confirming or correcting the judgment he may have formed, by the examination, after death, of the several organs and systems of the body; for though the information then acquired can be of no practical use in the individual case, and the seeking it may, with the ignorant, expose the medical man to Molière's sneer, "d'aviser et voir ce qu'il aurait fallu faire pour guérir un homme qui mourut hier," it may on a future occasion exempt him from doubt, or rescue him from error. It cannot be questioned that a much greater degree of precision than formerly prevailed in medical diagnosis has been introduced, and is in the course of being introduced, into this branch, since medical men have become duly aware of the importance of examining dead bodies for the purpose of determining the existence or non-existence, in particular diseases, of organic alterations of structure, and, when these exist, of ascertaining their nature and seat. But in endeavouring to connect the symptoms that manifest themselves during life, with the morbid alterations of structure found on examination after death, much attention is requisite, as has been already hinted, to enable us to discriminate between those structural changes that give rise to diseases, and those that only develop themselves during their progress, or the existence of which may be merely fortuitous. "Multum prodesse ad intelligendas morborum causas cadaverum sectionem," says Van Swieten in his Commentaries on Boerhaave's Lectures (sect. 1041), "nemo dubitat; interim tamen magnâ cautelâ hic opus est, ne pro morbi causa habeatur illud, quod potius morbi effectus est; multa enim in cadavere inveniuntur mutata per morbum ipsum, quæ non præ-exstiterant ante morbum." To assist us in this discrimination, it is very desirable to have an opportunity of making post-mortem examinations in every stage of the progress of a disease. But in some diseases in which there is no tendency to death, particularly in their early periods, it is only by availing ourselves of deaths accidentally occurring that we are able to ascertain whether the disease depends primarily on organic or structural lesions, and, if so, of what nature these may be.

It would perhaps be impossible to refer to a more happy illustration of the reciprocal light which the attentive examination of the symptoms that present themselves during life, and the careful inspection of the structural lesions met with after death, are calculated to throw upon one another, than is afforded by the connection traced by Dr Bright between a particular affection of the kidney (now well known to medical men under the name of its first accurate describer), and a train of symptoms too often forcing themselves on the attention of the medical practitioner, but which had never before been recognised as depending on a specific pathological condition or proximate cause.

It must, we conceive, be acknowledged upon all hands, that the farther medical inquiries have been pushed, the smaller has the number of diseases become which are not known to be connected with, if not immediately dependent upon, perceptible alterations in the structure of particular portions of the body; or, in other words, that the diseases reputed dynamic have gradually diminished, while those reputed organic or structural have proportionally increased in number. It may be doubted, however, whether medical men, in their anxiety to trace the symptoms of diseases to organic causes, have not occasionally attributed to structural alterations a greater influence in the production of these phenomena than they actually exercise. For, even when structural alterations are found in the organs which, during life, had exhibited symptoms of a deranged condition, it does not necessarily follow that these symptoms and organic alterations were immediately and necessarily connected. In many cases, indeed, the symptoms seem to depend rather on some superadded dynamical derangement, than on the change of texture which has occurred.

In corroboration of this opinion may be mentioned the well-ascertained facts, *first*, that the same organic lesion which in one individual is accompanied with well-marked symptoms, in another individual may give rise to no indication of its existence, which, indeed, may become known only on examination after death; *secondly*, that the same combination of symptoms which *post mortem* examination would lead us to refer in one case to obvious organic alterations, may be found in another case totally unconnected with any perceptible change in the structure of any part of the body; and, *thirdly*, that in some cases of disease in which organic alterations are found after death, the symptoms have exhibited during life a periodical or intermittent character, which could not be the case if they depended simply on organic alterations of structure, seeing that these are not subject to variation. Thus, in a large proportion of epileptic subjects, organic alterations have been met with in the encephalon; but, in the *first* place, it sometimes happens that similar organic alterations are found after death in cases in which no symptoms of epilepsy occurred; in the *second* place, in some cases of epilepsy, no marks of organic disease can be detected; and, in the *third* place, though the organic alterations found in a number of cases of epilepsy may possibly account for such deviations from the healthy exercise of their functions as are manifested by some epileptics *between* their paroxysms, we must suppose that some other morbid condition of the encephalon, not permanent in its existence, but only occasional in its occurrence, is requisite for the production of the paroxysms themselves. "We know," says an intelligent author,[1] "that morbid alterations in the substance of the brain sometimes produce periodic diseases, and that certain additional causes of excitement operating upon an unsound brain, one or other of the functions of that organ is for a time impeded, till the new cause ceases to operate, when the individual immediately returns to his former state of apparent health."

In attempting to distinguish between those diseases which are referrible to an organic pathological condition, and those which are to be considered as dynamical, in the sense that has elsewhere been explained (in the article PATHOLOGY), it is necessary also to keep in mind that a deranged exercise of some, at least, of the functions of the economy, though not originating in any perceptible alteration of structure, may in its continuance give rise to some such alteration. The morbid appearances met with on the examination of dead bodies may, consequently, sometimes stand in the relation of effect to the derangement of function, and the consequent symptoms, of which medical men are disposed to regard them as the cause. "Les troubles des fonctions de la vie," said M. Prost, "et les altérations organiques, sont la double source des maladies, qui s'enchaînent, s'accroissent, et *se reproduisent mutuellement*."[2]

There is another source of fallacy in the attempts made by medical men to refer the symptoms that present themselves during life to such altered appearances as are found after death, in the different textures and organs of the body. We allude to certain changes that are liable to occur during the last periods of life, or even subsequently to death, and which those who are not duly warned of their occurrence, or not aware of the characters by which they may be distinguished, are liable to regard as products of disease. Much has been done, of late years, to facilitate the distinction between truly morbid, and, as they are termed, pseudo-morbid appearances, particularly between those turgescences of the extreme vessels which do, and those which do not, depend on inflammatory action. But, even from the difficulties that have presented themselves in establishing the grounds of distinction between these two sets of appearances, it may be inferred, that when these distinctions were not sufficiently understood or attended to, the symptoms that had manifested themselves during life must not unfrequently have been supposed to find their explanation in altered appearances of different textures and organs, which were not in reality products of morbid action.

From these observations, it is obvious that medical men require to be at all times equally on their guard against attributing to mere dynamical disturbance morbid phenomena which depend upon organic alteration of structure, and against attributing to structural alterations phenomena that arise simply from dynamical derangement. (L.)

See reasons assigned by Dr Abercrombie (on Diseases of the Brain, 3d edit. p. 217) for believing that the affection which has been called *Serous* Apoplexy is to be considered as *Simple* Apoplexy (that is, apoplexy not depending on any perceptible deviation from healthy structure) terminating in effusion.

PHYSICAL GEOGRAPHY.

Physical Geography.

A TREATISE on physical geography should comprehend a description of the general structure of our planet, of the arrangement of the solid and liquid materials of which its surface consists, of the nature of the elastic invisible fluids with which it is surrounded, and an account of the distribution of the organized beings by which it is inhabited. A detailed description of a field so vast, of a range of subjects so multifarious, would embrace every branch of natural history; but the province of physical geography is understood to be limited to general views of the different subjects now indicated. These views, if founded on legitimate deductions from observed phenomena, should enable us to reduce to a few general principles the infinite variety of appearances presented to us by nature; and it is this generalization which in modern times has elevated the study to the dignity of a science. Physical geography, however, in this philosophical sense, is of very recent origin; much of every domain of terrestrial nature yet remains to be explored; the surface of our earth is still but partially known; and although each succeeding age adds prodigiously to the knowledge of mankind, this exhaustless field will, for ages to come, afford materials to exercise the industry and reward the investigations of the philosophical inquirer, ere physical geography approaches to its limits of perfection.

SECT. I.—*Position of the Earth in the System of the Universe; its Form, Magnitude, Density.*

The sublime conceptions of astronomy, founded on observation and on mathematical inductions, have taught us to consider the innumerable stars visible to the naked eye and indicated by the telescope, as so many suns, probably enlightening and gladdening unseen worlds, which revolve round each, as our earth and its kindred planets revolve round our glorious luminary. The stars nearest to our earth are grouped into constellations, for the convenience of descriptive astronomy; but the more distant appear to the eye as nebulous patches or streaks of diluted light, which the highest powers of optical instruments have barely enabled us to resolve partially into clusters of stars, which analogy would lead us to regard as myriads of other suns; while imagination, ranging through illimitable space, pictures still more remote orbs, whose light has for ages travelled the profound, without as yet reaching the abodes of men. Such lofty conceptions of infinite power and beneficence are calculated to elevate the mind which entertains them, and to afford a compensation to human vanity for the comparative insignificance of our earth in the scale of creation. The solar system, of which our planet forms only a small part, seems to be itself but a fragment of a more extended system, round the centre of which the observations of Maskelyne and Herschel have rendered it probable that the sun and the fixed stars all revolve.

The terraqueous globe, without including comets, is one of twenty-nine bodies wheeling round our sun. Of these, eleven are termed *primary planets*, and revolve round the sun as a common centre; the remaining eighteen are named moons, satellites, or secondary planets, because they also revolve round some one of the primaries. The earth is accompanied in her orbit by one of these satellites. The orbits of two other planets are included within her path round the sun. The orbit of the earth is elliptical, but differs so little from a circle, that, in estimating its diameter, it may be considered as such; and its semidiameter, or the earth's distance from the sun, as determined from various astronomical data, especially from the transits of Venus over the sun's disc, equals ninety-five millions of miles.

That the earth is globular, is proved by ships steering in a general direction, either westward or eastward, arriving again at the point of departure; and very satisfactorily by the phenomena exhibited by vessels in receding from an island in the ocean. At a short distance the hull of the ship is sunk below the horizon; a little farther and the *courses* or lower sails are lost; and soon only the upper sails are descried on the circular horizon. The rotundity of the earth is such, that when the eye is elevated six feet above the water, an object on its surface may be seen at a distance of three miles; and at all other altitudes of the eye, the distance of the utmost visible point varies as the square root of the altitude.

Form.

The earth, however, is not a perfect sphere, but is somewhat flattened at the poles, or forms what is termed an *oblate spheroid.* Newton attempted to ascertain the ellipticity of the earth by calculation; and, considering the effect of its diurnal velocity on a homogeneous fluid of the mean density of the earth, he determined its equatorial to be to its polar axis as 236 to 230; but he imagined, that if the density were greater at the centre than at the surface, the compression would be *greater* than in a spheroid of equal density. This error was pointed out by Huygens, who, on the supposition that the density increases regularly with the depth in the earth, estimated the relative axes as 578 to 579. But the determination of both philosophers is at variance with the results of geodesical experiments made about that time, and with the more refined measurements of meridional degrees in different parts of the earth in later times, as well as with the results of observations with the pendulum made by Maskelyne on the mountains of Perthshire, and the very recent investigations on the same subject by Forster, Sabine, Duperrey, Freycinet, Kater, Brisbane, and others.

On comparing the two methods of determining the figure of the earth, we are inclined to place more confidence in the result of measurements of meridional arcs than on the pendulum experiments, because the latter are liable to be disturbed by the geological structure of the regions in which they are made; and this is probably the cause why they accord less with each other than we should have expected from the delicacy of the apparatus, and the expertness of the observers. They give a greater ellipticity to the earth than the comparison of meridional arcs. The latter are not only more accordant with each other, but agree very nearly with the form deduced from the inequalities in the moon's motions, the equations for which were discovered by Laplace. The result of the whole is, that we may safely assume the ellipticity as equal to $\frac{1}{306}$th of the earth's axis; or the polar is to the equatorial diameter as 305 to 306.

Magni and m tions.

The solution of this problem is essential to the determination of the exact length of the radius of the earth; a most important problem in astronomy, as it is the *unit* by which we measure the planetary distances. But the determination of meridional arcs affords the solution of the point in question; and, aided by calculations, we obtain the following results in English miles:

Equatorial radius......................=	3963·7
Polar radius...............................=	3949·8
Ellipticity....................................=	13·9
Mean radius................................=	3956·75
Mean diameter............................=	7913·5
Mean circumference...................=	24871·

The oblate figure of the earth appears to be a consequence of its rotation on its axis. Mathematicians have demonstrated, that if the earth had been a homogeneous body, its ellipticity would have been greater than it really is; and if it had been so constituted that its density increased so as to be infinitely great at the centre, the ellipticity must have been much less. But the ellipticity is intermediate between these extremes, and perhaps coincides with that of a spheroid of equilibrium. The effect of centrifugal motion has evidently affected not only the liquid, but the solid materials of the globe; and this has been adduced by Playfair as a striking proof of the former fluidity of the solid materials of the earth.

The revolution of the earth on its axis is performed in a natural day, or, more strictly speaking, once in $23^h\ 56'\ 4''$; and as its mean circumference is $= 24871$ miles, it follows that any point in its equatorial surface has a rotatory motion of more than 1000 miles per hour. This velocity must gradually diminish to nothing at either pole. Whilst the earth is thus revolving on its axis, it has a progressive motion in its orbit. If we take the length of the earth's orbit at 600,000,000, its motion through space must exceed 68,490 miles in the hour.

Besides these two motions, the refinements of modern astronomy have determined two secular movements of extreme slowness, produced by the attractions of the other heavenly bodies of our system, namely, the motions which cause the *precession of the equinoxes*, and the *nutation of the earth's axis.* These motions, though important astronomical speculations, are little connected with geography; but it is otherwise with the diurnal and annual movements of our planet, the former of which produces the grateful vicissitudes of day and night, the latter the changes of the seasons. Both exercise remarkable influences upon the organized beings inhabiting the earth; and their consequences, therefore, deserve notice in a treatise of physical geography.

Various astronomical phenomena indicate that the density of the earth increases towards the centre. Cavendish endeavoured to estimate the mean density of the earth from the force of gravitation; and, from experiments with spheres of lead, he estimated it at 5·48. The investigations with the pendulum by Maskelyne and more recent observers have given it as equal to 4·71; and perhaps we shall not greatly err, if in round numbers we consider the mean density of the earth as equal to five times that of water. But the average density of the rocky masses which compose the crust of the earth does not exceed 2·5, or 2·8 at the utmost; and therefore the density of the interior parts must be considerably greater than that of the materials on the surface. Laplace considers it as probable that the density increases progressively with the depth, and that the globe may be composed of concentric beds symmetrically arranged round the centre of gravity. From these determinations, some philosophers have conjectured that the interior of the earth must consist of matter as ponderous as the metals, and that probably the metallic veins which we find near the surface may only be small portions of the central masses, expanded and projected through the concentric stony materials by the internal heat of the earth. If, however, we admit that the density of all matter is in the direct ratio of the pressure which it sustains, it has been shown, by a philosopher not less remarkable for the originality and boldness of his theoretical speculations, than for the profundity and sagacity of his philosophical investigations, that the interior of the earth cannot be a solid mass of any material with which we are acquainted, but "that our planet must have a very widely cavernous structure, and that we tread on a crust or shell whose thickness bears but a very small proportion to the diameter of its sphere;"[1] which, since an absolute void is inadmissible, he conjectures to be filled with *elemental heat*, or light in its most concentrated state, shining with the most intense refulgence.

SECT. II.—*General Distribution of the Land and Water.*

On glancing at a map of the world, we are immediately struck with the great extent of its superficies occupied by the waters, which are united into one great *ocean*, filling up the depressions which separate the more elevated portions of the solid crust of the globe, and dividing the land into detached masses of very various extent, which we denominate *continents*, *islands*, or *insulated rocks*. These divisions, however, differ only in size; the continent is but a larger island; and the insulated rock is merely the summit of a mountain, the flanks and base of which are buried below the general level of the sea.

We are in the habit of speaking of the four quarters of the world, and sometimes of its four continents; but it is sufficiently obvious that there are only two great distinct divisions or principal masses of the dry land to which the name of continent should be applied; the eastern, including Europe, Asia, and Africa, which, from being the earliest abodes of civilization, may be termed the *Old Continent;* and the western, or American, which is usually known as the *New Continent.* By confining the designation of continent to these prime divisions of the land, we shall find no difficulty in classing Australia with islands. The old continent includes three of the great divisions of the earth, Europe, Asia, and Africa; the western continent, though chiefly occupied by the descendants of Europeans, is naturally divided into two great portions, which in future ages may become as distinctly marked by political and moral differences as they are by geographical peculiarities.

The vast extent of Australia has induced some geographers to consider it as a continent; but it may more justly be reckoned the first of islands in magnitude; and it might be grouped with the numerous and extensive islands lying to the south-east of the old continent, as a fifth great division of the globe, under the title of the *Oceanic* or *Polynesian.*

The terms employed in describing the various forms of the land, and the subdivisions of the liquid surface of our planet, have been sufficiently noticed under the article GEOGRAPHY, to which the reader is referred.

The slightest glance at a map of the world will show, that there exists a greater accumulation of dry land in the northern than in the southern hemisphere. Recent voyages have indeed proved that this disproportion was over-rated by the geographers of the last age. The late discoveries of the extensive tracts of land to which the names of New Shetland, New Orkney, and Sandwich Land have been given, prove that considerable deductions must be made from what was at one time considered as the domain of the Antarctic Ocean. But the voyages of Cook, Furneaux, Weddell, and others, have shown that these, although extensive groups of islands, do not belong to a great antarctic continent; and even if such existed, the general form of the ancient, as well as of the western continent, towards the north, would still leave a great preponderance of dry land in the northern hemisphere. It is not unworthy of notice, that the proximate sides of the old and new continent seem as if they had mutually influenced the forms of each other; for where any remarkable projection of the one is perceived, we find an indentation nearly opposite in the other. Thus, the principal eastern projection of South America is almost opposite to the vast African *bight*, extending from Cape Palmas to Cape Negro; the great western projection of Africa is opposed to the basin of the Carribbean Sea and the Gulf of Mexico; and the north-eastern trending of the coasts of Europe is balanced by the opposite direction of the shores of North America.

---

[1] Leslie's Elements of Natural Philosophy, note I.

Land.

The general disposition of the land is different in each. In the old continent the principal extension is to the west and east; in the new it is to the north and south. In the former we may draw continuous straight lines of immense extent in different directions without encountering one sea. Thus a line from Cape de Verd in Western Africa will pass through continuous land till it reaches the promontory which separates the Yellow Sea from the Gulf of Leatong, a distance of 7800 geographical miles. One projected from Cape Palmas, on the Gulf of Guinea, to the Asiatic promontory called Tschcoutskoi-nos, will extend 8700; and another, from Tangier to the Cape of Good Hope, will be nearly 5800 geographical miles. The longest straight line which we can project on the land of the new continent is from Cumana to Tierra del Fuego, a distance of 4600 geographical miles; and the next, from Icy Cape to Puerto de los Angelos, on the western coast of Mexico, is about 4100. In the old continent the lines we have described have large portions of the surface on either hand; but in the new continent the greater part of the land is on the eastern side of the imaginary lines.

The greatest extension of each considerable division of the two continents lies in the direction of its principal mountain chains. This is strikingly exemplified in America, where the Rocky Mountains and Western Cordillera of Mexico in the northern, and the gigantic Andes in the southern hemisphere, pursue the general direction of the American continent. The greatest extent of Europe is from west to east, and this is the general direction of the chains of the Pyrenees, the Alps, the mountains which form the northern boundary of Turkey in Europe, and the Carpathians. A similar direction is pursued by Mount Taurus, and other ranges of Central Asia, the Himalaya chain, and the mountains of Thibet. In Africa the position of the mountain chains is less known; but the direction of the rivers, and the notices of travellers, would lead to the inference, that, on its eastern side, a spine of mountains, more or less interrupted, extends from Abyssinia towards the southern extremity of Africa. Even the direction of smaller portions of both worlds, as of islands and peninsulas, coincides with their principal mountain chains. This is well illustrated in Norway, in Italy, in the so-called peninsula of India, in Siam, Cambodia, Florida, and California, and on a smaller scale in the islands of Ceylon, Madagascar, Cuba, and Great Britain.

Ocean.

The expanse of the waters is termed the *Ocean;* but, for the convenience of descriptive geography, it is divided into several, though, strictly speaking, there is but one ocean; and the different seas form but parts of a vast whole, which communicate freely with each other, and can scarcely be considered as marked by definite limits. Most geographers speak of two grand oceans, which have derived their appellations from their position relative to the old continent.

I. *The Western Ocean*, which includes three principal subdivisions. 1. The *Northern Ocean*, of which the southern limits are the British coasts, and a line drawn thence to the southern extremity of Greenland. 2. The *Atlantic Ocean*, which should be limited to the south by the extreme projections of Guinea and Brazil. 3. The *Ethiopic Ocean*, which lies between the limits of the last, and a line joining the southern extremities of Africa and America. All three are sometimes, though less correctly, denominated the *Atlantic.*

II. *The Eastern Ocean*, which is also subdivided into three principal portions. 1. *The Indian Ocean*, comprehending the seas between Southern Africa, Australia, and the Malayan Islands. 2. The *Pacific Ocean*, extending from Behring's Straits to Cape Horn, and the southern side of Australia. It is often subdivided into the Northern and Southern Pacific, of which the limits are not well defined. 3. *The Austral* or *Southern Ocean*, which in general terms may be described as extending southwards from a line passing round the globe and touching Van Diemen's Land, and the Cape of Good Hope, and Cape Horn. With these main oceans various seas communicate, either by narrow straits, as the Persian Gulf, the Red Sea, the Mediterranean, and the Baltic; or by wider channels, as the Sea of Okhotsk, the Yellow Sea, the Sea of Hudson, and of Baffin; or by numerous openings, as the Sea of China, the Carribbean Sea, and the Mexican Gulf. The Euxine, the Caspian, the Sea of Aral, and of Baikal, and the magnificent fresh-water lakes of North America, have many of the characteristics of lakes; but their gigantic scale, and their important influence on the climate of the adjacent countries, entitle them to the designation of Inland Seas.

Propo betwe land a water.

The portions of the earth's surface which are covered by the waters bear a large proportion to the dry land. Dr Halley first suggested the idea of ascertaining the comparative surface of the land and water, by cutting them out of a map, and weighing them separately. It was by this means that he ascertained the relative area of the English counties. The astronomy of Dr Long, published in 1742, contains the application of this principle for ascertaining the relative surface of the land and water on the earth. He describes his having cut out each from the gores of Senex's sixteen-inch globes, and on carefully weighing them he obtained the ratio of the water to the land as 349 to 124, or very nearly as 3 to 1. Dr Long's experiment appears to have been conducted with great nicety; for Professor Rigaud of Cambridge has very lately confirmed it by a laborious and careful repetition upon the great scale. This latter gentleman used the gores printed for Addison's three-feet globes, which contain a superficies of 4071½ square inches. The gores of this magnificent globe are twenty-four in number. The torrid zone was divided at these lines and at the equator, and thus formed into forty-eight divisions; the divisions of the two temperate zones were also forty-eight, and these together made ninety-six divisions, each of which was carefully examined separately, divided into land and water, and accurately weighed in a balance which easily indicated one tenth of a grain.

The southern frigid zone was considered as wholly consisting of water; but the northern frigid zone, from longitude 180° to 270° west, was taken as land, and, from 270° to 360°, was computed to consist, one half of land and one half of water. The whole surface of the earth was supposed to be divided into 1000 parts, and all the estimates of the different regions were expressed in proportions of this standard. Rigaud's paper contains several tables, of which the following are the general results.

	Land.	Water.	Ratio.
North polar zone...	18·0263......	23·4437......	100 to 139
North temperate ...	126·6308......	132·5247......	100 ... 105
North half of torrid	52·5582......	146·8162......	100 ... 279
South ditto..........	46·1592......	158·2156......	100 ... 332
South temperate ...	22·5488......	236·6060......	100 ... 1049
South polar..........	... .	41·4700......	... ...
Whole sphere.......	265·9233......	734·0762......	100 ... 276
North hemisphere...	197·2153......	302·7846......	100 ... 154
South hemisphere...	68·7080......	431·2906......	100 ... 628
Whole torrid zone...	98·7171......	300·0318......	100 ... 204

This differs surprisingly little from the estimate of Dr Long, considering that each was deduced from the works of different geographers, and at a considerable interval of time. If we express the ratios of each determination, we shall have, in

Dr Long's estimate, the land to the water......... = 1 : 2·81
Professor Rigaud's.. = 1 : 2·76

And it is also deserving of notice that Rigaud's last estimate differs but little from his former experiment on Carey's twenty-one-inch globe; but both differ considerably from the calculations of Malte-Brun. As, however, that author has not furnished us with the elements of his calculation, it ought not to be put in competition with the elaborate investigations of Long and of Rigaud.

The dry superficies of each great division of the globe was ascertained by the same method; and the tables of Rigaud enable us to give an accurate comparative view of their relative area in thousandths of the earth's surface.

Europe	=15·6989
Asia	=88·7320
Africa	=59·5764
America	=91·2573
New Holland	= 9·9063
Smaller islands	= 0·7524
	265·9233

If we take the whole superficies of the globe=196,836,658 square miles, as the land is to the water in the proportion nearly of 266 to 734 it follows that the whole land occupies a surface of 52,363,231 square miles, and the ocean an area of 144,473,427 square miles.

Sect. III.—*Variations of the Surface.*

Besides the inequality produced by the oblate figure of the earth, different portions of its surface are at different distances from its centre. The dry land is elevated into mountains, depressed into valleys, or stretched out into plains, varying in extent and elevation above the sea; and the ocean itself must be considered as effused into a vast basin, seemingly diversified, like the dry land, with mountains, precipices, valleys, and plateaux of an infinite variety of shapes and dimensions. In fact, the whole dry land may be considered as a series of islands, or of plains and mountains, elevated above the general surface of the ambient fluid which occupies the deeper valleys that divide them.

The whole surface of the dry land is elevated more or less above the general level of the ocean; with one remarkable exception, which, however, has only of late years been detected. Barometrical measurements have shown that a vast area of Central Asia, no less than 18,000 square leagues, is considerably below the level of the ocean. This tract includes the Caspian and the Aral, the surfaces of which have recently been shown to be 101·2 feet lower than that of the Euxine. Should any convulsion of nature, such as earthquakes are known to produce in other quarters of the earth, depress the low sandy tract which now separates the sea of Azof and the Caspian, the waters of the Euxine, and also of the Mediterranean and the Atlantic, would inundate an enormous extent of the sandy *steppes* of Asia, and entirely change the climate and face of that portion of the earth.

Plains of greater or less extent, with inconsiderable inequalities, are found in every region. The most considerable plain in Europe is that which, commencing on the Northern Ocean, between the extremity of Jutland and the mouths of the Scheldt, extends eastwards through Prussia and Poland into Russia, and constitutes in that empire an almost unbroken plain, from the confines of the Frozen Ocean to the shores of the Euxine and the Caspian, until it meets the Uralian chain, which separates Northern Europe from Northern Asia. In this vast expanse, the surface is scarcely broken by any hills, except the inconsiderable ridge of Valdai, between Toropetz, Smolensk, and Moscow, which nowhere rises to 1200 feet above the sea. This magnificent plateau is divided by the Uralian Mountains from a still more extensive plain, which may be denominated the great plain of Northern Asia, the boundaries of which are the Altaian chain and the Icy Ocean. It commences at the eastern side of the Ural, and inclines towards the north-east until it almost touches the Northern Pacific Ocean. Both plains together form a remarkable feature in the surface of our earth, and being only interrupted by the Ural chain, which never exceeds 4500 feet in height, have been regarded by some geographers as but *one plateau;* which, thus considered, is the most extensive on our planet, with a medium breadth of 1100 miles, a length of 6000, and a surface of about 6,600,000 square miles. The surface of much of these two great plains is fertile; some of it is covered with heaths or swamps, producing dwarf birches, willows, and a stunted vegetation; a considerable part is shrouded in dark pine forests.

Far different in appearance are the enormous wastes of arid sand in Northern Africa and Central Asia, the vast *savannas* of the Mississippi and the Missouri, and the *pampas* and *llanos* of South America.

Deserts.

A prodigious zone of sand stretches like an ocean, in Northern Africa, between the ridges of Mount Atlas and the parallels of the Senegal and the Niger, and from the Atlantic to the narrow valley of the Nile. It may be said to cover a tract across that continent between the eighteenth and thirty-first degrees of north latitude, extending from long. 15° W. to 30° E. This enormous area may be considered as having a length of 2470 miles, a breadth of 900 miles, and consequently a superficies of about 2,200,000 square miles. It is, however, by no means an uniform surface of loose sand. In many parts the dreary waste is broken by low hills of naked sandstone, or by tracts of arid clay; occasionally it is enlivened in a few spots by verdant isles, or *oases,* of various extent, according as water finds its way to the parched surface. The principalities of Fezzan and Darfûr are the most considerable of these islands of the desert; but the most celebrated of these insulated spots is the far less considerable oasis of Siwah, the palms of which still wave over the ruins of the Temple of Ammon, and indicate the most ancient seat of African civilization.

Egypt, Nubia, and Sennaar, the eastern boundaries of this desert, would long ago have been overwhelmed by the moving sands of the western desert, but for the annual inundation of the majestic Nile; and thus the empire of sand would have stretched uninterruptedly into Arabia. As it is, the narrow valley of that river, and the Red Sea, are all that separate the African deserts from those of Asia. Soon after quitting the Nile, the traveller by the route of Suez encounters sand, which is continued into the centre of Arabia, where it forms the Desert of Nedsjed, extending to the valley of the Euphrates. The sandy zone then inclines northwards, enters Persia, and forms the saline deserts of Adjemi, Kerman, and Mekran; it is turned north-east by the valley of the Indus, passes through Caubul and Little Bukharia, till it joins the vast deserts of Cobi and Shamo, which occupy so large a portion of Central Asia between the Altaian and Mustag chains, and reach to the confines of China. The sandy zone thus traced throughout the breadth of the ancient continent, from Western Africa to the 120° of east longitude, has been computed to cover an area of 6,500,000 square miles; but the Asiatic portion of this tract includes many chains of mountains and fertile valleys. It is characterized by the occurrence of arid wastes of sand or clay, sometimes with saline incrustations on the surface, and is remarkably deficient in considerable rivers; except the Nile, the Euphrates, the Indus, and the Oxus, there are no large rivers in a region which embraces almost a fourth part of both Africa and Asia. This portion of Central Asia forms a series of elevated plains six thousand miles in length from west to east. "Some of these plains," says Humboldt, "are covered with herbage; others produce only evergreen saliferous plants, with fleshy and jointed stems; but a great number glitter from afar with a saline efflorescence, that crystallizes in the semblance of lichens, and covers the clayey soil with scattered patches like new-fallen snow."

From these elevated plains have issued the barbarous hordes which at different periods have swept like a whirlwind over the regions where the human intellect had achieved its proudest triumphs, and devastated the seats of Asiatic and European civilization. From this *officina gentium* have successively issued the Huns, the Avars, the Mongols, the Alans, and Uzes—the scourges of humanity; and possibly also the tribes by whom the American continent was originally peopled.

North American plains.

The great valley of the Mississippi is a magnificent plain, covered with primeval forests, or spreading in vast savannahs; but a great portion of it is liable to periodical inundations from the river. At 100 miles from the sea its annual inundation has a breadth of from 80 to 100 miles; and even at the mouth of the Ohio, which is 1000 miles from the sea, the inundating waters have the breadth of thirty miles. This shows the extreme flatness of the soil. The river has been extensively embanked, to rescue a portion of the rich soil from these inundations; but, during the season of the inundations, the greatest part of this extensive plain is still abandoned to the alligator and other reptiles, and to enormous herds of wild animals during the rest of the year.

The banks of the Lower Missouri, for 2500 miles, present a succession of fertile plains beyond the reach of inundations. This district, which may be considered as a continuation of the great valley of the Mississippi, exhibits an agreeable intermixture of natural prairies and forests, abounding in wild animals, which retreat before the rapidly-advancing tide of human colonization.

These immense plains are probably destined to become the abodes of a dense population, and perhaps the seat of a mighty empire, subject to few of the natural vicissitudes that impede the march of improvement, if we except the contingent risk of some mighty convulsion, by which the waters of the extensive fresh-water seas of Canada may be permitted to overwhelm this extensive realm with a far more formidable catastrophe than the deluge of Deucalion. Lake Superior has a depth of about 600 feet, and its surface is more than 300 feet above the level of the plains of the Mississippi. Should earthquakes disrupt the intervening barrier, the waters of that and the other great inland seas would sweep these plains with a devastation quite unparalleled in the history of our planet since the deluge of Noah.

South American plains.

The interior of South America presents plains not less extensive, the peculiarities of which have been sketched with a masterly hand by Humboldt. The first may be termed the valley or plain of the Orinoco. It is bounded on the north by the maritime ridge of Caraccas, on the south by the forests of Guiana, and extends westward to the mountain chain of New Granada, the summits of which are lost in perennial snow. It is a solitude of more than 20,000 square leagues.

The second is divided from the first by the mountain-arm which the Andes sends eastward to separate the waters of the Orinoco from those of the Marañon, an interrupted branch, stretching from the towering ridges of Popayan, to the humbler granitic Sierra de Tumucuraque, on the confines of Guiana. The southern boundary of this second plateau consists of the chains of Santa Cruz de la Sierra, of Chiquito, and Cuyaba, which separate it from the plains of the Paraguay, the Parana, and La Plata. The western boundary is the cordillera of the Andes. This territory includes the *llanos*, extended solitudes, with a scanty soil, destitute of trees, but covered with a luxuriant herbage, the consequence of the periodical inundations, which convert this portion of South America into inland seas; amidst the turbid waters of which, as has been forcibly described by Humboldt, may be seen herds of wild cattle and of horses, swimming from one gradually-diminishing island to another, in search of food, or escaping from the attacks of the jaguar, to become the prey of the alligator, or perhaps to be stunned by the strokes of the electric gymnotus. In the immense tract of country included in this second division, are some detached groups of mountains, indicated on the magnificent map of Olmedilla; but they are generally of inconsiderable elevation, and the face of the country may be considered as one enormous plain, or succession of contiguous plains, little elevated above the general level.

The third system of great South American plains forms the basins of the Paraguay and La Plata. This region includes the vast *pampas* of Buenos Ayres, extending from the foot of the eastern ridge of the Andes to the "sea-like Plata," and stretching southward into the cheerless deserts of Patagonia, presenting to the eye interminable plains, with a surface often as unvaried as the ocean, inhabited by vast herds of wild cattle and droves of horses; while the tall form of the *Rhea Americana*, a species of ostrich, frequently gives local peculiarity to the picture.

Table-lands.

Besides the extensive plains already described, which are either not much elevated above the sea, or rise by imperceptible degrees, there are other plains, with steep acclivities on every side, which have thence been termed *table-lands*. Some of these are very extended, and retain a general level of several thousand feet above the sea. Sometimes they are bordered with chains of mountains, much less elevated on the side towards the table-land than in the opposite direction; sometimes they have surfaces much undulated or broken. There are few table-lands in Europe of sufficient importance to be here noticed. The most considerable is that of Central Spain, embracing the two Castilles, which has a general elevation of nearly 2000 feet above the level of the sea. The barometer at Madrid has a mean height of about twenty-seven English inches, which, supposing the instrument on the shores to have a mean of thirty inches, would give to the capital of Spain an elevation of about 1900 English feet. The thermometer in winter often descends below the freezing point; and the *chæmerops* and the *agave*, which flourish luxuriantly in the plains around the table-land, are unknown at that elevation, though under the fortieth parallel of north latitude. The descent from this table-land on all sides is steep; and the transition from the arid and almost treeless plains of Castille, into the milder climate at the foot of the mountain ridges which support it, is marked by the vegetable productions of a warmer latitude.

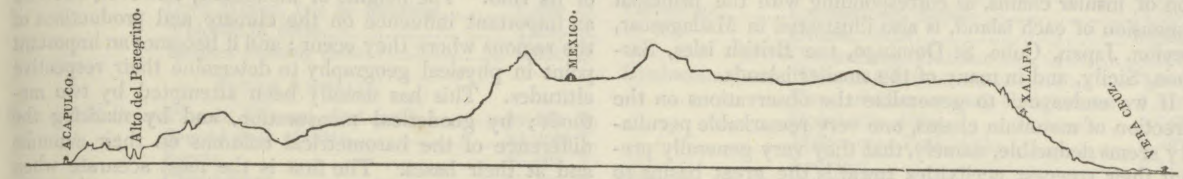
Our imperfect knowledge of Central Asia prevents any accurate notion of the extent and form of these remote regions; but there can be little doubt, that in this quarter there is the most extensive table-land on the face of our globe. The severity of the climate, the direction of the rivers flowing from it on every side, and the scanty information derived from Asiatic caravans, all indicate that there is a prodigious central elevation, supported on the north by the chain of the Altai, on the west by that of Belug Tag, on the south by the mountains of Thibet, and on the east by the chain of Sialki, which divides the country of the Mandshurs from their Tatar brethren of Mongolia. This enormous tract, however, can scarcely be described as consisting of one table-land; for it is intersected by the lofty mountain ranges of Alaki and Mus Tag, which are capped with perennial snows, and it contains the vast, treeless, sandy deserts of Cobi and Shamoo.

The central plateau of Asia, from the severity of its climate, is inferred by Humboldt to have an elevation of not less than 9000 or 10,000 feet above the sea; and this region, including Thibet and the desert of Shamoo, is believed to have a superficies of 1,500,000 square miles.

According to the observations of Olivier, Persia should likewise be considered as a table-land of great elevation. Southern India affords an excellent instance of a table-land, which includes the whole kingdom of Mysore. It stretches from the banks of the Kistna on the north, and is supported by the steep acclivities of the Western, and of the less abrupt Eastern Ghauts. The general elevation of this region is about 3000 feet; but at its southern extremity it abuts against a smaller though much loftier table-land, the district of the Neilgherry Hills, which, till lately, was almost unknown to Europeans. A good account of it has recently been published at Calcutta, by Dr Robert Baikie, from which we learn that the district occupies an area of 600 or 700 square miles, between the eleventh and twelfth degrees of north latitude, and the seventy-sixth and seventy-seventh degrees of east longitude. The general level of its finely-undulated surface is between six and seven thousand feet above the sea. It is connected with the Mysore country by a neck of land about fifteen miles in width; but its northern flank towers above that kingdom by 3500 feet, and it is separated from the subjacent plains of Malabar and Coimbetore by an almost precipitous boundary 7000 feet in perpendicular altitude. The surface is fertile, the climate mild and salubrious; and there the invalid, suffering from the baneful influence of a residence in the sultry plains of India, finds a European climate. The barometer varies from 22·840 to 23·220; whilst the thermometer throughout the year ranges from 73°·51 to 42°, and has a mean of 52°·50. The quantity of rain is = 42·251 inches; heavy rain falls on nineteen days, showers on eighty days, and the clear days are 179 in the year.

The great similarity of this Indian table-land, in elevation, in salubrity, and in climate, to the more extensive table-land of Mexico in North America, is remarkable.

No. 1.



The Mexican plateau (No. 1) has also a general elevation of 7000 feet above the sea; it rises as abruptly as the Neilgherry district, especially from Vera Cruz, and in a single day the European may escape from the pestilential atmosphere of the plains, to an elevation at which the *black vomit* is unknown. The sea-coasts of Mexico are hot and unhealthy at certain seasons, and are known to the natives by the name of *Tierras Calientes*, or burning regions, producing the vegetable riches of the torrid zone. A single day, from Vera Cruz, suffices to reach the height of 4000 feet, where there reigns a perpetual spring; and this region, termed *Tierras Templadas*, though often enveloped in clouds and fogs, is healthy. On ascending to the height of 7000 feet, the traveller gains the *Tierras Frias* of the Mexicans, or great table-land, which has generally a mean temperature of 63° Fahrenheit. It produces the cerealia of Europe, and the vine and the olive flourish on its plains. But its surface is varied by hills; and along its margins, stupendous peaks, such as Orizaba, Popocateptl, and the Sierra Nevada of Mexico, have their summits far above the limits of perpetual snow. There are other plains in Mexico which are more than 1000 feet above the general level of the great plateau. Such is the plain of Toluca, where the climate is severe, and the mean temperature so low that the olive there refuses to ripen its fruit.

Several less extensive table-lands are included between the two lofty parallel chains which constitute the Southern Andes. Thus the plains of Quito and Riobamba are true table-lands; the general level of the first being 8000 feet above the sea, and the city of Riobamba having an elevation of 10,800 feet, so that it is probably the most elevated city in the world.

Mountain chains and ranges of hills are separated by valleys, which have obtained the names of *ravines*, *dells*, *defiles*, or *passes*, when narrow and difficult of access. These chiefly occur among lofty mountains, and sometimes present mural precipices of wonderful sublimity. Narrow valleys often present a striking coincidence in the position of the salient and receding angles of their opposite sides. This has been well described, as observed in the Pyrenees, by Ramond; and some geologists have considered it as a proof that such valleys had been formed by the sudden disruption of continuous strata.

In describing valleys, geologists likewise distinguish them into different kinds, according to their respective relation to the mountain ranges on which they occur. *Principal valleys* are such as run parallel to and separate great chains of mountains. Those which have a direction at a considerable angle with the principal chain, separating the branches or arms of the mountain chain, are termed *lateral valleys;* and the smaller ones, running into these lateral arms, are denominated *subordinate valleys*. The lateral open into the principal, and the subordinate into the lateral valleys.

Sometimes we find a valley, consisting of a chain or succession of basin-shaped cavities, at different levels, separated from each other by narrow gorges. Such appearances are not uncommon among all mountains; and several examples occur in our Highland glens, as in Glen Roy, Glen Gluoy, and Glen Spean, where the fancied parallel roads mark the successive heights at which the waters formerly stood, until the rocky barriers which pent them up were opened.

Sometimes a valley has a circular form, or is *basin-shaped*, and on all hands surrounded with mountains, excepting at a narrow gorge, where the waters of the valley make their escape. Two of the most remarkable instances of this are found in Bohemia and in Cashmere. The former consists of a single circular valley, nearly 200 miles in diameter, which appears at one time to have been a vast lake, until the formation of the defile in the Erzgebirge, through which the Elbe escapes into Saxony. Cashmere is a fertile valley of difficult approach, nearly circular, and ninety miles in diameter, embraced by the arms of the Himalaya Mountains. Native tradition represents it as a lake, until one of the Hindu deities burst the rocky boundary, by the formation of the ravine through which the Vidusta now pours its waters.

Some valleys contain large rivers and lakes, from which there is no issue or outlet. Such valleys have not yet been drained by the giving way of some point of their boundaries. Central Asia affords many instances of this species of valley, as in the districts around the Koko-noi, the Lokenor, the lakes of Zaizan, Kirgha, and Palkati, and the Sea of Aral. A very remarkable instance occurs amidst the loftiest peaks of the Andes, in the valley which contains the great lake of Titicaca, which the ancient Peruvians regarded as sacred, the residence of the founder of their monarchy, and which is sufficiently remarkable, by its extent, and the sublimity of the surrounding scenery.

The most elevated portions of the earth's surface are either connected in extensive mountain chains, or they exist in aggregated groups branching from a common centre, or they form insulated heights, rising more or less abruptly from plains. We have seen that the direction of mountain chains is that of the principal extension of the regions in which they occur; and the same thing holds good in peninsulas and islands, in which we generally find the chains longitudinal. Thus the principal mountains of Europe, Asia, and America form extensive chains in the direction of the greatest extent of each of these divisions of the earth.

The direction of peninsular chains is well seen in Norway, in the Apennines, in the mountains of the western side of Arabia, in the Ghauts of India, and in the mountains of Corea, Kamtschatka, and California. The direction of insular chains, as corresponding with the principal dimension of each island, is also illustrated in Madagascar, Ceylon, Japan, Cuba, St Domingo, the British isles, Sardinia, Sicily, and in many of the smaller islands.

If we endeavour to generalize the observations on the direction of mountain chains, one very remarkable peculiarity seems deducible, namely, that they very generally present their steepest acclivities towards the great basins to which they are contiguous, while they slope more gradually in the opposite direction; and on examining their intimate structure, we find their stratified beds dipping generally *from* the basins to which their escarpments are presented. Thus the ridges of the Scandinavian peninsula present their boldest escarpments to the basin of the Northern Atlantic; while the opposite ranges of Greenland and Iceland also show their steepest acclivities towards that basin. Round the shores of the Mediterranean the same arrangements are especially observable. The lofty ridge of the Atlas is very bold on the northern side, and declines more gradually towards the Sahara. The chain of Spanish mountains which skirt the Mediterranean, from Gibraltar to the Pyrenees, present their escarpments towards that sea; and the Maritime Alps of France, the mountains of Switzerland and the Tyrol, of Istria, Dalmatia, and Thrace, all present their most precipitous sides to the basin of the Mediterranean. We believe that the considerable chain which in Asia Minor extends from Mount Ida to the country around Scanderoon, has the escarpment directed towards the Levant seas; while the mountains of Armenia present their boldest declivities to the basin of the Euxine, and the Caucasus and mountains of Mazanderan towards that of the Caspian. The escarpment of the great chain of Africa, termed that of Lupata, which seems to be prolonged from the lofty mountains of Abyssinia to the south of the Mozambique Channel, would appear, from the little we have learned of its structure, to face the basin of the Indian Ocean; and we know that the steepest declivities of the Western Ghauts of India are directed towards the same basin. The mighty spine of the American continent, from the shores of the Arctic Frozen Ocean to the extremity of South America, through a course of more than 8600 British miles, presents a series of rugged precipices to the vast basin of the Pacific; and, if we might indulge in one sweeping generalization, it would seem that the chains stretching from the Persian Gulf eastward through Thibet, and thence bending to the north-east through Mongolia and Northern China to Tscheoutskoi-nos on the Frozen Ocean, present their fronts also to the Pacific Ocean.

As such coincidences can scarcely be considered as accidental, they afford a wide field for speculation. Can we suppose that appearances, on such an immense scale, have any relation to the operation of the force which caused the elevation of the land, acting towards a central point, and producing the dip of the elevated strata all around, from a common axis of movement? Such speculations, aided by the position of volcanoes, and other mountains of igneous formation, might lead us to infer the direction of the great lines of subterranean disturbances which have modified the appearance of the crust of the earth.

The inequalities of the earth's surface, however considerable they may appear to the eye that contemplates them, bear but a trifling proportion to a sphere of nearly 8000 miles in diameter. The loftiest peaks are not quite five miles in height above the sea; and we may obtain some idea of their effects on its general form, by considering, that such inequalities on the surface of our earth produce no greater proportional deviation from its spherical shape than a roughness equal to $\frac{1}{1600}$th of an inch would on a ball an inch in diameter; not so considerable as the inequalities produced upon the form of an orange by the papillæ of its rind. The heights of mountains, however, exercise an important influence on the climate and productions of the regions where they occur; and it becomes an important point in physical geography to determine their respective altitudes. This has usually been attempted by two methods; by geodesical mensuration, and by marking the difference of the barometrical columns on their summits and at their bases. The first is the most accurate when we can obtain a level base at a moderate distance from the height to be ascertained, and when the measurements of the angles are carefully taken by expert operators, and with good trigonometrical instruments. The use of the barometer is confined to accessible heights; but it is much more easily managed, under such circumstances, and requires little more than attention to the true height of the barometrical column, corrected for the temperature of the instrument and of the ambient air. In variable climates, accuracy would require synchronous observations at the foot and on the summit of the height to be ascertained; but in tropical climates, or even in the south of Europe, the barometer scarcely varies throughout the year at the level of the sea, and therefore such measurements are more easily made. The methods of both kinds of observation are sufficiently detailed in the articles BAROMETRICAL MEASUREMENTS and TRIGONOMETRY.

Accessible heights have also been estimated by the fall of the thermometer on ascending. It has been found that, in our latitudes, an ascent of every 300 feet may be considered as equivalent to a fall of 1° of Fahrenheit's thermometer; but this formula does not answer so well either in high or in low latitudes.

It has also been proposed to measure such elevations by marking the temperature at which water boils at the base and on the summit. A convenient instrument for such observations was invented by the Rev. F. Wollaston, but it is liable to accidents in carriage; and, on the whole, geologists trust either to barometrical or to trigonometrical observations for measuring mountain elevations.

The most lofty mountains in general form parts of extensive chains; but there are many instances of great elevations being attained by isolated peaks. Instances of the former are familiar in the Alps, the Carpathians, the Himalaya, and the Andes; of the latter, in the towering summits of Ætna, Teneriffe, and Mouna Roa in the Sandwich Islands. But such detached elevations are either active or extinct volcanoes.

In the following table we have arranged the heights of mountains, according to the regions in which they occur; and marked the method of determination by the letters B. and T. according as the determination has been made by the barometer or by trigonometrical operations, while E. signifies estimated height.

Physical Geography.

Table of Heights of Mountains, &c.

AFRICA.

Abyssinia	Mountains of Geesh	15,000	E.
	Amid	13,000	E.
	Lamalmon	11,200	E.
	Gondar	8,450	T.
	Taranta	7,800	T.
Morocco	Atlas, two peaks of	11,400	T.
	Abyla or Ape's Hill	3,000?	E.
	Mountains near Fez	10,000?	E.
South Africa	Chain of Lupata	12,000	E.
	Niewveldt, Cape of Good Hope	10,000	E.
	Kom, ditto	5,000	E.
	Khamies, ditto	4,300	E.
	Table Mountains, ditto	3,582	T.
	Devil's Head, ditto	3,315	T.
	Lion's Head, ditto	2,166	T.
African Islands	Teneriffe, the peak	12,236	B.
	Trigo, Canaries	7,400	B.
	Ruivo, Madeira	5,162	T.
	Diana's Peak, St Helena	2,692	T.
	Gros Morne, Isle de Bourbon	9,600	B.
	Volcano in ditto	7,680	B.
	Bonnet Pointu, ditto	6,050	B.

SOUTH AMERICA.

Peru and Bolivia	Pico de Illimani, first peak	24,450	T.
	Second peak of ditto	24,200	T.
	Sorata	25,000	T.
	Chimborazo	21,440	T.
	Antisana, v.	19,150	B.
	Cotopaxi, v.	18,890	B.
	Tunguragua, v.	16,579	B.
	Pichincha, v.	15,940	B.
	Antiquipa, v.	17,800	T.
	Corazon	15,800	T.
	Potosi	16,000	B.
	Defile of Assuay	15,540	B.
	Huancavelica	14,960	T.
	Pass of Quindiu	11,500	B.
	Lake of Titicaca	12,000	B.
	City of Rio Bamba	10,800	B.
	City of Quito	9,356	T.
Columbia	Nevado de Merida	16,420	T.
	Nevado de Sta Martha	15,200	T.
	Volcan de Duida	8,467	T.
	Guadarrama	6,400	T.
	City of Bogota de Sta Fe	8,650	T.
	Mountains of Venezuela	5,000	E.
	Guachano	5,250	B.
	Silla de Caraccas	8,432	T.
	Tumiriquiri	6,250	B.

NORTH AMERICA.

Mexico	Volcan de Popocateptl	17,716	T.
	Pico de Orizaba	17,371	T.
	Nevado de Mexico	15,700	T.
	Nevado de Toluca	15,159	T.
	Coffre de Perote	13,514	T.
	Cerro de Axusco	12,052	B.
	Pico de Tancitaro	10,498	B.
	Volcan de Colima	9,186	B.
	Volcan de Jorullo	4,267	B.
	City of Mexico	7,470	B.
	City of Toluca	8,818	B.

From this table it appears that the loftiest pinnacles of our earth are to be found in the Himalaya range. Some of them attain an elevation a mile higher than Chimborazo, which was long regarded as the loftiest mountain on the globe. Of late years our countryman Mr Pentland has measured several mountains in Upper Peru, especially near the Lake of Titicaca, much higher than Chimborazo; and Sorata, one of these, is only surpassed by a few peaks in the great Indian chain. Although those who first attempted to measure the summits of the Himalaya appear to have exaggerated their real altitude, succeeding observers have shown that we must consider that range as the most elevated on the globe, and the peak of Dhawala-giri as the sovereign of mountains.

Human habitations, and even considerable towns, have been erected in very elevated stations on mountain chains. Dr Gerard states, that in the valley of Sulei, in the Himalaya Mountains, there is a village at the enormous elevation of 14,700 feet above the sea, and that rye is cultivated as high as 14,900 feet. Several travellers have found the revered temple of Kedar-Nath to be elevated not less than 12,000 feet. America presents some extraordinary examples of the same kind.

The mines of Potosi	=	16,080 feet.
Town of Potosi	=	13,350 ...
Shepherds' huts on Antisana	=	13,200 ...
Lake and plain of Titicaca	=	12,700 ...
City of Riobamba	=	10,800 ...
City of Quito	=	9,356 ...
City of Toluca, Mexico	=	8,818 ...
City of Mexico	=	7,470 ...

In Europe we have the following.

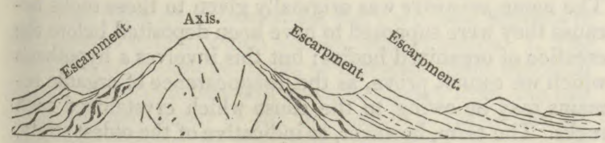
Hospice de St Gothard	=	6,790 ...
Director's house at Leadhills, the highest habitation in Britain	=	1,280 ...

Sect. IV.—*General Arrangement of the Solid Materials of the Globe.*

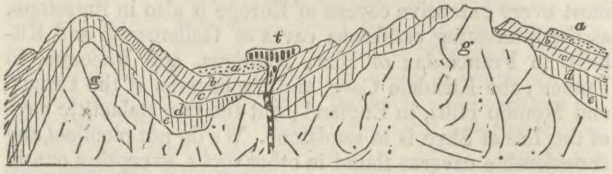
A particular description of the solid materials of our earth has been given under the articles Geology and Mineralogy; but it is our business to present here a brief statement of their general distribution.

Persons unaccustomed to examine the structure of the crust of our earth are apt to imagine that mineral masses present but a confused congeries of stony matter, without any order or particular arrangement. Nothing, however, can be more erroneous. Wherever water-courses, artificial excavations, or abrupt precipices, expose the structure of the crust of the earth, we find very striking appearances of the agency of causes which must have acted with great uniformity over vast portions of its surface, and which have produced a general resemblance between the structure of countries widely distant from each other. A large portion of the solid materials is arranged in beds, varying in extent and thickness, but everywhere indicating the operation of one common agent. These beds are sometimes slightly coherent, as when composed of clay or sand; at other times they are consolidated stony bodies, arranged in parallel layers, which are often subdivided into thinner portions by seams or joints, and preserve their parallelism for a great extent, whether their position be horizontal, or at different degrees of inclination. Such beds are termed *strata*, and the general fact is expressed by the term *stratification.* Sometimes we find a succession of strata of the same rock in juxtaposition; at other times there are strata of different substances interposed or alternating with the principal rock. The position of strata in plains is generally but little inclined towards the horizon; but as we ascend mountains, the strata are usually inclined, sometimes nearly, or even absolutely vertical. When a mountain, or a chain of mountains, is lofty, it is not unusual to find the strata inclined from the centre or axis of the chain towards either hand (No. 2); and in such cases we generally find the strata reposing on a different kind of rock, which has no appearance of having a seamed or stratified structure. Such rocks may also occur in plains; they have frequently a granular or crystalline structure, and form an important class of stony bodies. Hence the distribution of rocks into two great divisions, the stratified and unstratified. Both divisions present instances of rocks which either appear simple or homogeneous to the eye, or consist of stony bodies, which are evidently composed of two or more materials. Instances of the one occur in clay-slate, limestone, quartz-rock, and basalt; of the other in mica-slate, gneiss, granite, and porphyry. The visible axis of a mountain chain is very often some species of unstratified rock, and stratified materials usually form its flanks. In other instances no unstratified material is visible at the axis, as far as we can trace the structure of a mountain. But whenever the mountain is much elevated, or steep, and its sides ploughed by torrents, it is very rare not to find some unstratified material as the nucleus upon which the inclined strata rest (No. 3, *g*). We are not, however, to assume, that in the order of superposition the stratified materials are invariably above the unstratified. Though this holds good in a great number of cases, we frequently observe vast masses of unstratified rock directly resting upon regular strata (No. 3, *t*). In some cases we are able to show such irregular masses connected with other similar materials much lower in the series of rocks, by one or more lines of communication penetrating the strata, which, according to their shape and size, have obtained the name of veins or dykes. Instances of this occur frequently in mountains into the composition of which trap-rocks enter (No. 4).

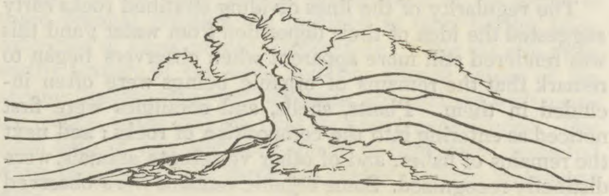
No. 2.



No. 3.



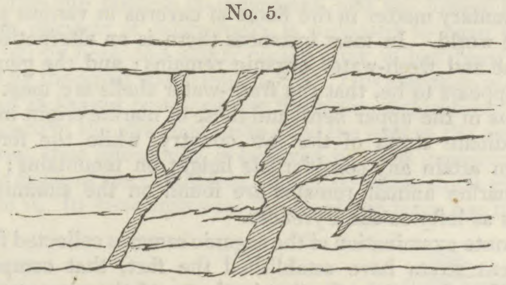
No. 4.



There are, however, other kinds of veins which we cannot so readily trace to larger masses of mineral substances. The most familiar instances of such occur in metallic veins (No. 5). They may often be observed penetrating both stratified and unstratified matter, in the greatest diversity of forms and directions; sometimes in very minute threads, expanding to the dimensions of many feet, or even yards, and repeatedly contracting again to the thickness of a fraction of an inch.

Veins.

No. 5.



Sometimes mineral bodies form irregular masses entirely enclosed in the rocks in which they occur, varying in weight from a few grains to many tons, without any perceptible trace of the mode by which they were so introduced. Occasionally long fissures occur, which are not filled up by any solid material; sometimes also cavities are left in the more solid species of rocks, the sides of which are lined with crystalline bodies of various kinds. Sometimes these fissures and cavities are of enormous extent, forming vast caverns in the bowels of the earth, which are either empty or filled with water. Instances of these on the great scale occur in the limestone strata of many countries, especially of Carniola and North America; and on a less scale in France, Germany, and in our own island. The cavern of Adelsberg, in Carniola, extending to three leagues in its various ramifications, and containing a subterranean lake and river, affords an example of the extent of caverns in limestone rocks; and the no less remarkable Mammoth Cave of Kentucky, which has been traced to the extent of nine or ten miles, is an American example of the same formation. Almost every extensive cavern of Europe is also in limestone, as the interesting ossiferous caves of Gailenreuth and Küloch, in Franconia; of Bize, Somières, and Racogne, in France; the Kirkdale Cave, and the caverns of the Craven and Mendip Hills, in England; but the fine stalactitic cave of the Isle of Skye is in sandstone. We do not recollect any considerable caverns found in other rocks, excepting one in the schist of the island of Thermiæ in the Archipelago, and the vast Icelandic cavern of Surtshellir, in a current of lava which had flowed from the Bald Yökul. This last cavern, as described by Henderson, is nearly a mile in length, and appears to have been formed in the flowing lava by the disengagement of gaseous matters; as it has all the appearance of being the consequence of an enormous air-bubble, having its arched roof ornamented with coralliform projections of black slag. Perhaps we may also give as an exception the small but remarkable columnar cave at Staffa, which is in trap-rock.

Such is the general structure of the solid crust of our earth. But when we examine the rocks more minutely, we find other striking peculiarities belonging to each, which, besides the order of their superposition, mark different eras in their formation.

Basis of Geology.

The regularity of the lines dividing stratified rocks early suggested the idea of their deposition from water; and this was rendered still more apparent when observers began to remark that the remains of organic beings were often included in them. Plants, shells, and corallines were first noticed as entering into the composition of rocks; and next the remains of fishes, and of other vertebrate animals, were distinctly recognized. Some organic remains were observed to pervade limestone rocks at great depths in the earth, and upon very high mountains; and remains of plants, and even stems of trees, were found fossilized, or converted into stone, in the strata of the coal formation. Some remains of marine genera of animals were detected in slaty strata which do not belong to either of these two kinds of rocks; and, lastly, the remains of quadrupeds were recognised in the sandy marl and gypseous deposits which in some countries lie immediately below the soil, or were imbedded in sedimentary matter in the floors of caverns in various parts of the world. In most instances there is an alternation of marine and fresh-water organic remains; and the general fact appears to be, that the fresh-water shells are most numerous in the upper beds, and those of marine origin in the subordinate strata of the low country, while the former seldom attain any considerable height on mountains; but the marine animal remains are found on the summits of ridges as lofty as the Pyrenees.

Minute examination of the organic remains collected from different strata have established the fact, that comparatively but few of the fossil animals are of the same species with those of the same families now living; and we cannot doubt that whole genera and orders have disappeared from the face of the earth. It is only in the upper deposits that any species identical with those now existing have been detected. Where the organic bodies are completely fossilized, very few if any living species can be recognised; and generally the recent species most nearly allied to the fossils are now no longer to be found in the adjacent seas or regions. Thus the fossil-shells and corallines of northern countries, in both continents, have their congeners (when such are known) generally in tropical climates; and the fossil-trees of the British coal-fields have a greater affinity to the *tree-ferns* and *cyacadeæ* of southern regions, than to any sort of European vegetation.

These circumstances are too remarkable not to have suggested theoretical speculations. Accordingly, geology has long been conversant with sublime, but hasty, and sometimes unwarranted generalizations; and though she is still remote from the period when a lasting theory shall safely and satisfactorily embrace the explanation of observed phenomena, yet she has begun to assume a more philosophical aspect. Facts are rapidly accumulating, and the deductions of ingenious men, applying the science of number and calculation to this interesting study, have already established a basis on which future observers may erect a philosophical theory of the earth.

The crystalline arrangements of the particles of a considerable portion of the solid materials of the earth's crust, indicate, beyond doubt, that the particles have been once in a state of such freedom of movement as to assume a determinate order, that is, in a certain degree of fluidity; and hence the geologist assumes that such minerals must have either been softened, or melted by heat, or have been suspended in a fluid medium. The phenomena of stratification, and the incorporation of organized bodies in different rocks, are not less certain indications that a large portion of stony matter has obtained its present form by subsidence from water; and this constitutes the grand basis of geological reasoning. The second link in the chain, the relative age of the different strata, is derived from the order of their succession. As the strata bear the marks of deposition from water, it is obvious that the lowest in the series must have been the first deposited, and the upper beds the most recent formations. No such chronological data are afforded by the unstratified rocks, though their relations to stratified materials afford just inferences respecting their true era; but it is from the examination of the strata of any country that we can arrive at a just conception of its geological history.

Geolo epoch

Relative geological age, then, is to be sought by a careful examination of the superposition of the strata; and as the observation of organic remains has shown a succession of living forms to be peculiar to each series of rocks, the knowledge of such remains forms an important feature in modern geology. Certain fossils are peculiar to certain formations, and we are sometimes able to identify particular rock formations by their included organized remains. It is on such a basis that the most generally received classification of strata has been established; and geologists now usually divide them into three great classes, *the primary*, *secondary*, and *tertiary*.

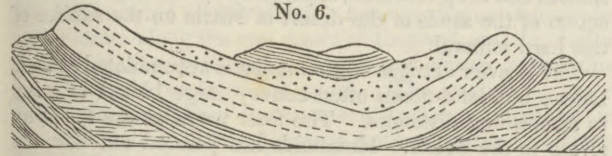
Prima strata.

The primary strata are such as do not include any organic bodies. They are the lowest in the series of strata, and are found to repose on crystalline unstratified rocks, generally on granite, which, as far as we have penetrated the crust, has the appearance of being the general fundamental rock. The name *primitive* was originally given to these rocks because they were supposed to have been deposited before the creation of organized bodies; but this involves a hypothesis which we cannot prove, as the disappearance of organic remains may be owing to the cause which crystallized such rocks. The term, however, as indicative of the oldest strata, is convenient, although the theory which suggested it may be exploded.

Secon strata.

The secondary strata are generally less crystalline in structure, and in their lower beds the organic remains are few, being chiefly marine productions; but these increase in number and variety in the upper beds, which may be said to end with the chalk formation. The organized bodies are chiefly marine productions, as zoophyta, crustacea, shells, fishes; sometimes reptiles, amphibia, and plants are also found in secondary strata. During the deposition of the secondary strata the land appears to have been gradually rising above the level of the waters which once covered it; and during the same period there are marks of more sudden changes or disturbances among them, which are most probably to be accounted for by the forcible irruption of ignigenous rocks from the bowels of the earth. The land appears to have attained extensive elevations above the waters after the deposition of the cretaceous formation, the newest of the secondary rocks; and another system of deposits now begins to be developed. Stratified rocks appear now also to have been formed by deposition from fresh water, as is proved by the abundant remains of animals inhabiting that element; and this is one characteristic of the *tertiary strata.* It is true, that in the coal-fields of the secondary rocks, we occasionally find alternations of sea and fresh water animals; which may be explained by such formations having taken place in extensive estuaries, into which rivers have flowed. But the decided alternations of fresh and salt water deposits are peculiarly characteristic of the tertiary period; and this, with the limitation of such formations to particular basins or circumscribed hollows, enables us to recognise them. Some of the best recognised of these beds are the Paris Basin, the London Basin (No. 6), and that of the Isle of Wight and the opposite coast of Hampshire. Tertiary beds appear to be entirely wanting in Scotland and in Ireland; but they occur in Germany, in Spain, in Italy, and in different parts of Asia and America. In the upper strata of the tertiary period we find many shells similar to living animals in the adjacent seas; and bones of extinct mammalia also occur among their beds. Sometimes the remains belong to genera of which no species now exists; at other times to genera of which we still possess living types.

No. 6.



M. Deshayes has attempted to ascertain the dates of tertiary deposits by the number of living species they contain, considering that which contains the greatest number of existing species the most recent. He distinguishes three tertiary epochs. The most ancient is that of the Paris, London, and Hampshire Basins, in which he finds 3·5 per cent. of living shells, corresponding to the Eocene deposits of Mr Lyell. The middle group includes the basins of the south-west of France, of Baden, Vienna, Hungary, and Moravia. Among these he found 15·2 per cent. of living shells; and this corresponds to Lyell's Miocene period. The most recent strata include the tertiary beds of Italy, Sicily, Spain, of the south-east of France, the Morea, and the *crag* formation of England. In it he detected 45·4 per cent. of living shells; and it corresponds to the Pliocene formation of Mr Lyell.

Besides these great formations, there are local deposits of more limited extent, which we may slightly notice. 1. The formations at present going on, or elevated within historical periods, by earthquakes and volcanic agency from the bed of the sea, and added to the dry land. 2. Lacustrine deposits, now forming the rock called *travertino*, or giving rise to marly sediments. This last deposit, at Big-bone-Lick, in Kentucky, contains bones of the mastodon and other mammalia, with fresh-water shells; and at Market Weighton, in Yorkshire, the bones of the elephant, with those of the lion and the wolf. 3. The incrustations of calcareous matters cementing fragments of other rocks, as in the *nagelfluhe* of the Germans; or including bones of living species, which have fallen or have been washed into caves and fissures. 4. Superficial deposits of gravel and sand, evidently the produce of rivers or of floods, which sometimes contain bones of elephants, the rhinoceros, &c., and are distinguished by the name of diluvian. 5. Erratic blocks of different rocks, which have been removed from their original beds, and scattered over extensive tracts. The most remarkable instances of this transportation are the profusion of large blocks of the zircon syenite of Norway, scattered over all the north of Germany, to the very foot of the Jura chain; of the granites of the Alps on the summit of the Jura, and beyond it into France; and of the granite of Shap Fell, over the intervening mountains, into Lancashire and Yorkshire. 6. The deposits formed by volcanoes at present in activity, consisting either of ashes, mud, or lava; to which we may add the obsidian, pumice beds, trachyte, and basalts of extinct volcanoes. The best characterized and most remarkable of the former are the ashes which have buried Pompeii, the mud eruptions of Tunguragua in 1797, the enormous lava streams of the Skaptàr Yökul in 1783, and of Vesuvius and of Ætna at numerous periods: of the latter, we have examples in the obsidian of Lipari, Ascension Island, and Teneriffe; in the pumice beds of Lipari and of Auvergne; in the trachytes of the latter country, of Germany, and Italy; and in the basalts of almost every region.

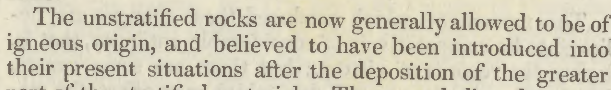
Stratified rocks.

The general opinion now entertained by geologists is, that the stratified materials of the earth's crust have been horizontally deposited from water at different eras, but that the unstratified rocks have been produced by the action of a high temperature. The consolidation of the older strata is supposed to have been accomplished by heat, produced either by internal changes among the elements of which they consist, or derived from a source of heat deep seated in the earth. The less crystalline state of the secondary strata, with the more perfect preservation of the forms of these organic remains, are ascribed to their having been subjected to a less intense temperature; while the still more earthy texture of the beds, and less altered nature of the organic bodies among tertiary strata, are ascribed, with seeming justice, to the still less heat they have experienced. The loose beds of clay and sand appear to have been deposited when the crust of our earth was cooled down to its present state.

Unstratified rocks.

The unstratified rocks are now generally allowed to be of igneous origin, and believed to have been introduced into their present situations after the deposition of the greater part of the stratified materials. These are believed to have been liquefied by heat in the bowels of the earth, and forced upwards by the expansion of elastic matter, either in a softened state, or, in some instances, after they had been melted and again consolidated. In this view, granite, which so often forms the nucleus of mountains, and the lowest basis we can discover of other rocks, is supposed to have been acted on by heat, and slowly cooled after it had been elevated by the agent which liquefied it. This elevation is considered as having produced the fractures, dislocations, and elevations of the stratified rocks; and the heat of the melted material, thus introduced, is believed by most geologists to be the cause of the crystalline state of the older strata which rest on it. In some instances the elevating force has tilted the strata to an absolutely vertical position; at other times it has carried up detached portions of the strata, and separated them from the principal bed, or even inverted the order of their superposition in considerable masses (No. 7). The injection of the fluid matter of granite between some of the strata, has given rise to the rare appearance of beds of this

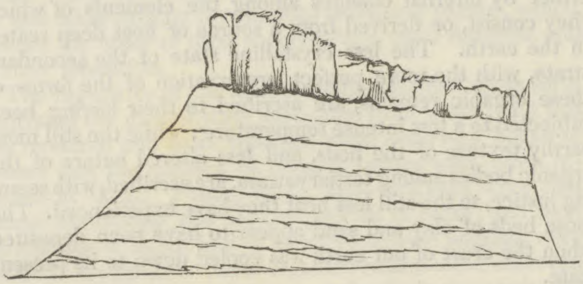
No. 7.



material; and when the force applied has rent or fissured the different strata, some of the liquefied matter has formed granitic veins, penetrating the stratified matter in different directions.

Trap-rocks, in like manner, are now generally considered as the immediate progeny of fire. They are occasionally found as interposed beds, or sometimes alternate with other matter, in distinct but thick beds, though not exhibiting the seams of true stratification. Most geologists regard such appearances as the consequence of subaqueous volcanic eruptions, in which liquid matter had flowed out of craters, spread over the adjacent strata, and been covered by aqueous depositions; after which a repetition of the same process may have given rise to such alternations. The more ordinary appearance of trap-rocks, especially of greenstone and basalt, is either in the form of veins penetrating stratified rocks, or as forming mountain caps, or huge beds superimposed on secondary, or sometimes on tertiary strata. Familiar instances of these veins occur in all coal-fields, more especially in the vicinity of the great coal deposits around Edinburgh and Glasgow. Arthur's Seat, near the former, affords a good example of a mountain capped by trap reposing on sandstone strata; and Salisbury Craig, of a vast bed of greenstone overlying the same strata (No. 8). The chalk of Antrim is in the same manner covered by greenstone and basalt; and the tertiary strata of Auvergne are often concealed by beds of trachyte or other ignigenous rocks.

No. 8.



The movements which produced these changes are believed to be comparatively of considerable antiquity, that is, before the records of history; but there are some causes, in operation at the present day, which may affect the stability of those more ancient arrangements, and which therefore we must now briefly consider.

Sect. V.—*Circumstances affecting the present Order of Geological Phenomena.*

These may be considered as four: Atmospherical action; the effect of the waters of the ocean and of floods; disturbances occasioned by earthquakes; and the influence of volcanoes.

Action of the elements.

1. Atmospherical action is slow, but constant. The united influences of winds and rains serve to form *detritus*, by which the higher portions of the earth's surface are gradually lowered, and the materials thus abraded carried by streams and rivers to the sea. The consequence must be, a very gradual change in the relative level of the land and the ocean. The abrasion of mountains by torrents and impetuous rivers produces deposits of gravel, sand, and mud in plains at their feet. These effects are increased by the sudden bursting of water long pent up in the bowels of a mountain, or dammed up in an alpine lake; thus giving rise to the phenomena which are termed *debacles*. Instances of the fall of mountains have been frequently afforded in the Alps and other lofty mountains. The fall of the Rossberg was foretold by General Pfeffer, several years before it happened, from the existence of enormous collections of water in its bowels; and in the recent fall of one of the *Aiguilles*, which border the southern side of the valley of Chamouni, a vast torrent of liquid mud, bearing before it woods and vast masses of rock, proved the influence which dammed-up water had in the catastrophe. The fall of the mountain of Chiavenna, which in 1618 buried the town of Pleurs and all its inhabitants, appears to have been produced by water insinuating itself among the shaly strata which underlie the limestone beds in the Italian Alps. Among lofty mountains, another cause of disintegration is perpetually at work. The accumulation of snow, and the formation of glaciers on their steep acclivities, where there is a considerable difference between the summer and winter temperature of the climate, is a powerful cause of the degradation of these elevations. The fall of the thundering avalanche, and the movements of the increasing glacier, from its own weight, detach vast masses of rocks, and hurl them into the valleys below. Even the action of minute particles of sand, moved by the winds for a succession of ages, is capable of wearing the hardest stones. Thus the polished surface of the granite of Sinai has been, with great probability, attributed to the perpetual descent of quartz sand over the rock; and we have in our possession nodules of Egyptian jasper, the exterior of which has been worn into smooth and deep channels, apparently by the long-continued action of the sands of the desert of Nitria on the surface of this hard mineral.

The heavier detritus of mountains is accumulated at their bases; but land-floods often convey large blocks of stone to astonishing distances. The finer particles are swept by rivers to the ocean. Humboldt has pointed out how the Gulf of Mexico is rapidly filling up by the sedimentary deposits from the waters of the Mississippi and other rivers which fall into that inland sea. The turbid waters of the Orinoco and the Marañon discolour the ocean to the distance of 300 miles from their mouths; and there can be no doubt that the formation of the flat land of Guiana, now about 100 miles in width, from the most eastern ridge of hills, is principally the alluvial deposition of these mighty rivers. The waters of the Ganges, at the highest inundation, are stated by Rennell to contain an enormous quantity of sedimentary matter; and we can hence conceive how the flat shores of the Hoogly, and the other branches, have originally been formed, and how the Bay of Bengal may, in process of time, be materially altered in its depth. Another striking instance of the effect of rivers in *silting* up a confined sea is to be observed in the Gulf of Leaotong, or upper part of the Yellow Sea, into which a great part of the detritus of Northern China is deposited by its numerous large rivers, and by the effects of the strong currents in that inland sea. Staunton has calculated that the Yellow River alone discharges into the Yellow Sea more than 2,000,000 of cubic feet of earthy matter every hour. The matter carried down by the Nile and the Po is well known to affect the extent and deepness of the adjacent seas; and the distance of Ravenna from the present shores of the Mediterranean (between three and four miles) proves how a comparatively small river like the Montone, pouring its sediment into a still bay, has altered the situation of a port, where, in the ages even of the lower empire, the Roman fleets used to anchor. These facts would lead to the supposition that the land was gaining upon the sea; but there are other circumstances which are at least equivalent to this change.

The natural consequence, as was well pointed out by Playfair in his Illustrations of the Huttonian Theory, and previously noticed by Manfredi, must be to elevate the surface of the ocean, by the deposits of detritus in its bed. This rise is most conspicuous in inland seas. Thus, on the western side of Italy, the ruins of the palace of Tiberius at Capræ are now wholly covered by the sea; and the far-famed temple of Serapis, situated on the Bay of Baiæ, has its pavement below the present level of the Mediterranean. Manfredi states, that when the ancient pavement of the cathedral of Ravenna was discovered in 1731, it was found to be a foot below the present high-water mark; from which we must infer that the level of the Adriatic had risen at least as much in 1500 years. The shores of Baiæ may have had the level altered by the vicinity of an active volcano, and the temple alluded to shows indications of more than one upheaving and depression of the land; but the district of Ravenna is all alluvial; and a similar rising was noticed at Venice by Zendrini.

The same fact is attested by observations along our own coasts. The submarine forest on the coast of Lincoln, first described by Correa de Serra in the Philosophical Transactions, 1799, proves a rise in the level of the sea; and the tradition, that the Godwin Sands once formed part of the fertile domain of the Saxon earl of that name, has probably a fair claim to be arranged with the same phenomenon.

ct. of
e

2. The wasting of the land by the waves of the ocean, and the overwhelming of large tracts by the sea, are nearly allied facts. The changes on our own coasts, and on the countries between the Rhine and the Elbe, afford striking instances of the encroachments of the ocean on the land. Even where the rocky boundaries are the most solid, the ceaseless action of the waves has wasted and disintegrated the cliffs around all our shores; but the destruction of the softer strata along the east coasts of England, and the chalky heights of Dover, is still going on, and affords undeniable proofs of the power of this agent. The swallowing up of whole districts along the coasts of Yorkshire is shown in the annihilation of the villages of Auburn, Hyde, and Hartburn, and in the ravages of the sea on the neck of land uniting the Spurnhead with the rest of the country. We have authentic records of the destruction of Dunwich, on the coast of Suffolk; and near Harwich, in Essex, the sea is annually encroaching. The Start islet was within the memory of man a part of the island of Sandey, in the Orkneys.

Still more remarkable changes have taken place on the coasts of Holland and Friesland within historical periods. Well-known instances of this occurred in the devastation which accompanied the formation of the Zuyder Zee in the beginning of the thirteenth century; in the successive encroachments of the ocean, which formed the islands near the Texel in 1251; and in the disappearance of the once fertile district of North Friesland, the only remnants of which, since the disastrous 11th of October 1634, are the three small islets of Noordstrand.

Such changes have occurred in various parts of the earth. Some of them, especially the overwhelming of low sea-coasts, may be owing to the gradual elevation of the level of the sea by detritus washed into it; but probably still more is due to changes in the level of the land by unequal subsidence, the consequence of earthquakes.

Acti of
earth

3. The terrible effects of earthquakes have attracted attention in every age, and records of some of such convulsions have descended to us from very remote ages. No period of our earth's history has been more noted for the violence and extent of earthquakes than that between the first, third, and the middle of the fourteenth century. China was terribly convulsed for ten years from 1333, when Kiang-si, its capital, was swallowed up; mountains were engulfed, and floods, occasioned by the obstruction of the course of rivers, destroyed vast multitudes of human beings. The succussions extended westwards, and Asia Minor and Egypt were violently shaken in 1346; while in the following year severe earthquakes were experienced in Cyprus, Greece, and Italy. In 1692, the island of Jamaica was visited by a most terrible earthquake, in which enormous masses of earth and rock were detached from the Blue Mountains, and vast quantities of timber, hurled from their flanks, covered the adjacent sea like floating islands. It was during this earthquake that the city of Port Royal, with a tract of adjacent land, estimated at 1000 acres, sunk, in one minute, into the deep. In the succeeding year great earthquakes in Sicily destroyed the city of Catania, and a hundred and forty other towns and villages in that island, where upwards of 100,000 persons perished. In 1746, Lower Peru suffered severely from this calamity. The ocean burst in upon the land with irresistible force, when the barrier of land sunk into the sea, Lima was overwhelmed, and the present port of Callao formed. These convulsions were accompanied by eruptions of water and mud from several volcanoes among the Andes. In 1750, the city of Conception, in Chili, disappeared during an earthquake, and the sea rolled over it. In 1755, Lisbon was in a great measure destroyed by one of the most terrible earthquakes that ever visited Europe. The mountain chains between the Douro and the Tagus were most dreadfully convulsed. The new mole at Lisbon, to which multitudes had fled, as to a place of safety, suddenly sunk into an hideous abyss, and not one body floated to the surface, nor were any fragments of the vessels sucked into the chasm rendered up, and on the spot there is now an hundred fathoms of water. In this awful convulsion at Lisbon sixty thousand persons perished in about six minutes. A violent shock threw down the greatest part of the city, and the sea retired, leaving the bar momentarily dry; but suddenly a mighty wave, fifty feet high, rolled in on the devoted city. The extent of the *terræ motus*, on this occasion, is very remarkable. The violence of the shocks, which were accompanied by a fearful subterranean noise, like the loudest thunder, was chiefly felt in Portugal, Spain, and Northern Africa; but its effects were perceived over a considerable part of Europe, and were even experienced in the West Indies. Our Scottish lakes, particularly Loch Ness and Loch Lomond, rose and fell repeatedly on that dreadful day. Ships at sea were affected by the shocks, as if they had struck on rocks, and their crews were in some instances thrown down by the violence of the concussions. In 1766, the island of Trinidad, and great part of Colombia, were violently agitated by earthquakes; an islet in the Orinoco disappeared, and land in other parts of the coast was raised above the waters. In 1772, the lofty volcano of Papandayang (the loftiest mountain in Java) disappeared, and an area around, fifteen miles by six, was swallowed up. Most terrible earthquakes desolated Calabria in 1783. This calamity has been admirably described by several writers, among whom we may mention Dr Vivenzio, Grimaldi, Sir William Hamilton, Dolomieu, and the commission of the Royal Academy of Naples. The violence of the shocks was chiefly felt in the Farther Calabria, and in the neighbourhood of Messina. The principal agitation was felt over an area of five hundred square miles. Many sudden sinkings of the land were perceived, numerous fissures were formed, and partial elevations were effected in some places. The greatest depressions happened at Terra Nuova, Oppido, Sinopoli, and Santa Christina: a fissure a mile in length, a hundred and five feet in width, and thirty feet in depth, opened at Plaisano; another about the same length, and a hundred feet in depth, was formed at Cerzulle; and at La Fortuna a chasm a quarter of a mile in length, thirty feet in width, and two hundred and twenty-five feet in depth, suddenly opened in the ground. In some districts considerable mountain-slips, or the separation of huge masses of earth and rock, took place; and along the Straits of Messina, in the neighbourhood of Scylla, the cliff of Gian-Greco, a mile in length, was precipitated on the subjacent houses and gardens. A fragment detached by the earthquake from Monte Jaci crushed multitudes who had fled to the shore for safety; and at the same moment a wave broke on the devoted shore, and swept away the aged prince of Scylla, and numbers of his people.

In the year 1797, Upper Peru was terribly convulsed. The shocks of earthquakes continued with great violence for three months, and the face of the country in the centre of the convulsion was totally changed. In 1811, violent earthquakes shook the valley of the Mississippi, by which lakes of considerable extent disappeared, and new ones were formed; but these were less terrific than the catastrophe which destroyed the city of Caraccas in 1812. On the 26th of March there were heard subterraneous thunderings; the ground undulated, as if agitated by a boiling liquid, and at one shock this fine city entombed in its ruins 10,000 of its inhabitants. During the earthquake the great lake of Maracaibo had its level lowered, and the riven earth at Puerto Cabello and Valencia poured forth enormous torrents of water. It is remarkable, that the volcano of St Vincent, which had been perfectly quiescent for a century, burst out with prodigious violence on the 27th of April in the same year, and threw out clouds of ashes, which rose to an immense height into the air. Much of the island was ruined by showers of scoriæ and ashes; and such was the violence of the eruption, that the decks of vessels 200 miles to windward of St Vincent were covered with an impalpable dust. On the day of this eruption subterranean thunderings were distinctly heard at Caraccas, and even on the Rio Apure, 210 leagues in a right line from St Vincent. In the eruption of Tomboro, about to be noticed, the earthquakes extended throughout an area a thousand miles in diameter, a considerable tract of land at the foot of the mountain disappeared in the waves, and the port of Bima, where ships of war could formerly anchor, was ruined by the upraising of a shoal. On the 19th of November 1822, Chili was visited by a most destructive earthquake. The shock was strongly felt at the same time throughout a line of coast 1200 miles in extent. It is stated, on good authority, that the coast for one hundred miles sustained an elevation of from two to four feet; and about a mile inland from Valparaiso it was raised from six to seven feet. The sudden elevation of the coast was indicated by shell-fish being found adherent to the rocks considerably above high-water mark. The shocks continued until the end of September in the following year; and the area over which the permanent alteration of level extended is believed to embrace the country from the base of the Andes to the sea, a surface of not less than 100,000 square miles. In 1827 Popayan and Bogota suffered most severely from earthquakes, during which vast fissures opened in the elevated plains around the latter city.

The last earthquake in Europe occurred in Murcia in 1829, near Alicante. Several villages in an area of above four square miles were thrown down by vertical movements in the valley through which the Rio Segura flows, and many small fissures were formed in the alluvial soil; while black mud, sand, and marine shells were thrown up from small cavities formed near the sea. Such are some of the severer earthquakes on record; but less considerable shocks are of frequent occurrence in various countries, especially in South America and in Italy. Smart shocks are occasionally felt in Scotland. They have often occurred at Comrie in Perthshire. A smart shock rent the spire on the town-hall of Inverness in the year 1816; and another earthquake was felt at Lancaster in 1834, which shattered chimneys, and alarmed the inhabitants. But all the shocks experienced in our island have fortunately been insignificant compared to those which have been felt in many other countries.

Action of volcanoes.

4. The alterations produced on our earth's surface by volcanoes in activity within historical periods appear to be underrated by some writers. Few geologists now will be disposed to doubt that most of the phenomena of earthquakes are the consequences of volcanic fire. The coincidence of those formidable shakings of the earth with volcanic eruptions, and the distance to which such agitations have been felt, show that the causes of both are deep-seated in the earth, and that they are probably the consequences of elastic matter formed by subterranean heat. We shall say nothing of the almost universal diffusion of trap-rocks, which, under the name of trachyte, basalt, greenstone, and trap-tuffa, are now generally admitted to be of igneous origin, nor of the true craters of extinct volcanoes which abound in France, Germany, and many other parts of the earth, but which have ceased to emit any eruption within known periods, and confine our attention to those mountains now either in active combustion, or which have been so within historical periods. Gay-Lussac enumerates 163 volcanoes active at the present time; and Professor Jameson gives the following distribution of 193 volcanoes in a state of present activity:

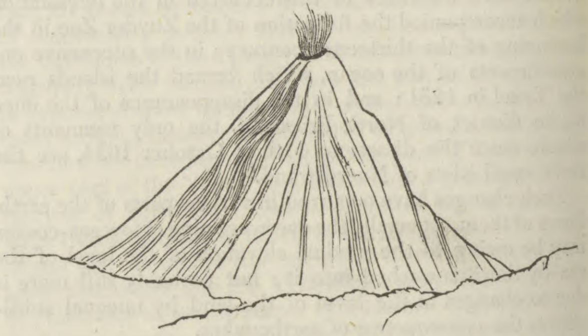
Continent of Europe	1	Continent of Amcrica	87
European islands	12	American islands	19
Continent of Asia	8		
Asiatic isles	58		193
African islands	8		

To these we may add the gigantic crater of Kirauea, in Hawaiah, one of the Sandwich Islands; the volcano of Tomboro, in the isle of Sumbawa; the volcano of Tofua, in the Friendly Islands; that of Barren Island, one of the Andamans, in the Bay of Bengal; to which we may perhaps add the submarine volcanoes which have suddenly risen from the bosom of the deep, but soon afterwards have again disappeared, as that of Nyoë, off the coast of Iceland; Sabrina, off St Michaels, in the Azores; and Graham's Island, not far from the east coast of Sicily.

The substances ejected by volcanoes consist either of melted stony matter termed *lava*, of *scoriæ*, of ashes, of sand, of muddy eruptions, or of vast quantities of hot and fetid water, always accompanied by earthquakes and subterranean thunderings, and generally by columns of flame or of dense smoke.

The general form of a volcano is a truncated cone, often isolated, and having a circular depression or spiracle on or near its summit, which is named a *crater*. From this crater smoke is perpetually issuing; sometimes flame appears, or volleys of ignited stones are projected into the air. From the dark cloud of smoke emitted during eruptions, vivid lightnings are usually seen to dart; and the vapours of sulphur, ammonia, or of muriatic acid, are often emitted. Sometimes the boiling lava is elevated from the bowels of the mountain to its terminal crater, fills that cavity entirely, and descends from the cone in streams of liquid fire, which concretes as it cools on the surface, but continues to move on with resistless force till it congeals into stone, though it often retains its heat for long periods. At other times the elasticity of the pent-up matter is incapable of forcing the lava to the highest crater; but the liquefied material bursts through the flanks of the mountain, and pours into the plains. Sometimes the volcanic cone is included in an exterior one; a circumstance on which Von Buch has founded his theory of *craters of elevation* (No. 10). The strata or beds in both concs are inclined from the general axis. The projectile power of volcanoes is prodigious. The dust of the volcano of St Vincent was carried more than 200 miles

No. 9.



No. 10.

eastward of that island, and must have attained a vast elevation, to obviate the effect of the trade-wind in its descent. It is stated, on credible authority, that Vesuvius has projected large stones 3600 feet above its summit; and Cotopaxi was ascertained by the French academicians to have hurled a rock, calculated to weigh 200 tons, to the distance of three leagues, or more than ten English miles.

Instances of volcanic eruptions are by no means rare. There are fifty-nine or sixty eruptions of Ætna recorded by historians, and about fifty-two of Vesuvius. The first eruptions of Ætna are lost in the remoteness of antiquity. Vesuvius was not in existence as an active volcano till the year seventy-nine of the Christian era, when the ancient crater presented a slight circular hollow, the sides of which were overgrown with wild vines, and the exterior of the cone was well cultivated. In the eruption which then took place, Stabiæ, Herculanum, and Pompeii were destroyed, and the elder Pliny lost his life. Stromboli appears to have been an active volcano from 300 years before Christ, and is still in a state of incessant activity, ejecting flame and red-hot stones in quick succession. The most noted eruption of Ætna was probably that of 1699, when, from a long rent on its flank, it poured out a stream of lava, which in its course to the sea destroyed fourteen towns and villages, some of which contained three or four thousand inhabitants. This current is fifteen miles in length, about 600 yards at its broadest part, and there it is forty feet deep. Vesuvius has more frequently been active in our own times than Ætna. One of its most terrible eruptions was that of 1538, when Monte Nuovo was forced up in two days to the height of 413 feet, and with a circumference of 8000 feet. Another happened in 1631, which covered with lava most of the villages at its foot, and sent forth torrents of boiling water. In little more than a century it has had eighteen eruptions. The eruption of 1794 has been well described by Breislac, who estimates one of its streams of lava on that occasion as containing upwards of forty-six millions of cubic feet. It again burned with great fury in 1805, 1813, and in 1822. We possess lavas of this latter period so strongly impregnated with sulphuric and muriatic acids, that they destroy every species of vegetable material they rest on; and, when recent, the specimens smelled strong of the latter acid. The volcanoes of Iceland have been in activity ever since the island was discovered, in the ninth century. Hekla, though not the most considerable of these, from its position and its former activity, is the best known. It has had many formidable eruptions, twenty-two of which have been noted in about 800 years; and in the same period we have notices of twenty eruptions from five other Icelandic volcanoes. A succession of eruptions of Hekla lasted for six years; but the most severe convulsions of that country happened in 1783, when the dreadful eruption of the Skaptàr Yökul burst forth, and did not cease till the following year. About a month before this terrible catastrophe a submarine volcano elevated the crater of Nyoë, seventy miles south-west of Cape Reikianes, and threw out such an immense quantity of scoriæ as to cover the sea, to the distance of 150 miles, with a stream which impeded the progress of ships making the island; and portions of this eruption floated as far as the Shetland and Orkney Islands. Nyoë emitted smoke and scoriæ from several apertures; but within a year the island disappeared, and a shoal marks its former site. On the 8th of June the Skaptàr Yökul threw out smoke; on the 10th an enormous current of molten lava flowed from numerous cones on the Yökul, which, dividing into two main streams, pursued its course to the sea, filling up the beds of two large rivers, and covering an immense extent of once productive country. The horrors of the scene were aggravated by the enormous torrents of boiling water produced by the liquefaction of the glaciers that covered the Yökul, and by incessant showers of ashes which darkened the sun; stream of lava succeeded stream from the 10th of June to the end of August, at short intervals; and noxious emanations destroyed numbers of those whom fire and water had spared. From this calamity Iceland has never recovered; for within the space of two years the island, in consequence of this eruption, lost 9336 persons, 11,460 head of cattle, 28,000 horses, and 190,480 sheep. The extent of the principal stream of lava is fifty miles in length; its greatest breadth is from twelve to fifteen miles; in the plains its general depth is 100 feet, but in the channel of the Skaptà River, which it dried up, it is 600 feet in perpendicular depth. The south-western side of Iceland appears to be one vast focus of subterranean fire; for the several eruptions of the Oræfa, the Skeiderà, Sida, and Skaptàr Yökuls, seem but as occasional *outbreakings* from one immense volcanic fissure, which really belongs to the same chain of icy mountains.

Volcanoes of Eastern Islands.

The volcanic formations of Java have been well examined by Dr Horsfield, who describes them as extending throughout the centre of that noble island. They form a chain, in which thirty-eight large mountains, evidently volcanic, are conspicuous, and attain an elevation of from 5000 to 12,000 feet. Most of them are no longer in activity. Tankuban Prahu has been quiescent for a series of ages; but its crater contains a large lake, a mile and a half in circumference, and 250 feet deep, from one side of which sulphureous vapour issues with great violence. Papandayang was once the largest of the Javan volcanoes; but in August 1772 the greatest part of it was swallowed up during an eruption. A luminous cloud at first seemed to envelope the mountain, prodigious quantities of ashes were ejected, which destroyed forty villages, and an area of fifteen miles by six was entirely swallowed up.

The eruption of Tomboro, in the island of Sumbawa, in the year 1815, described by Sir Stamford Raffles, is one of the most violent on record. The earthquakes caused by this eruption were felt over a circle with a radius of 1000 miles; and all around to the distance of 300 miles the quantity of ashes excited terror and dismay. In Java, though 300 miles in a direct line from Sumbawa, the sky at mid-day was darkened by dense clouds of fine dust ejected from the volcano. In Sumbawa it was attended by a whirlwind of surprising fury, which lasted for an hour, sweeping away trees and houses in its career. The explosions commenced on the ceasing of the whirlwind. They began on the 5th of April, and continued until the 15th of July. Whole villages were swept away, and upwards of 12,000 persons perished in this eruption. Vast numbers of trees, torn up by the whirlwind, strewed the ocean to a considerable extent. Raffles states that the explosions of Tomboro were distinctly heard in a circle with a diameter of 1700 miles; and that the quantity of light scoriæ and pumice it threw out within a week formed a bed on the ocean two feet in thickness, and many miles in extent, which impeded ships in approaching Sumatra.

Volcanoes of South America.

The volcanoes of America claim notice, not only from their magnitude and number, but from the peculiarities of their position. Several of the most lofty mountains of the South American Andes are active volcanoes. Cotopaxi has an elevation of 16,800 feet above the sea; the volcanoes of Mecas and Antisana equal 17,000 feet, and Tunguragua 16,500 feet. Humboldt considers these enormous cones as the spiracles of one prodigious volcanic vault, stretching from south to north, which presents an area of 600 square leagues; and he regards them as merely different summits of the same volcanic mass. "The fire issues sometimes from one, sometimes from another, of these summits. The obstructed craters appear to us to be extinguished volcanoes; but we may presume, that while Cotopaxi or Tunguragua have only one or two eruptions in the course of a century, the fire is not less active under the city of Quito, under Pichincha, and Imbaburu."

The connection of the volcano of Pasto, in New Granada, with the volcanoes of Quito, was strikingly displayed in 1797. A column of black smoke had continued for several months to issue from the Volcan de Pasto; but, to the surprise of the inhabitants, this smoke suddenly disappeared on the 4th of February 1797, at the precise moment when, at sixty-five leagues from the city of Pasto, the city of Riobamba, near Tunguragua, was destroyed by a terrific earthquake.

The eruption of Tunguragua, on the 4th of February 1797, was of a very extraordinary nature. The country around, to the extent of forty leagues from south to north and twenty leagues from east to west, sustained an undulatory movement of extreme violence, which lasted four minutes. In the district around the mountain every town was levelled with the ground, and the cities of Riobamba and Quero were buried under the ruins of the impending mountains. The base of Tunguragua was riven asunder, and poured out, from numerous apertures, streams of water and mud, which accumulated in the valleys to 600 feet in depth. The mud covered everything, blocked up the channels of the rivers, forming lakes which remained for more than eighty days. Fetid, suffocating exhalations were emitted by the lake Quilotoa, and it is said that flames also issued. The covering of mud, and the levelling of elevated portions of the country, totally changed its face. The shocks continued to be violent for upwards of three months, and were felt over a district 170 leagues from south to north, and 140 from west to east. It was during this eruption that the curious fishes, *Pimelodes Cyclopum*, were discovered in the ejected water of the volcano. They are supposed to be generated in subterranean lakes in the bowels of the mountain, and only to be brought to light by such an explosion. There are no less than sixteen active volcanoes in Chili, the eruptions of which are confined to the valleys of the Andes. A line of volcanoes in South America may be distinctly traced from 5° to 6° of south latitude, running parallel to the ocean, and occupying the highest ridges of the Andes.

Volcanoes of North America.

In North America, Mexico presents a chain of active volcanoes crossing the general direction of the cordillera of Anahuac from east to west. It commences on the coasts of the Mexican Gulf, with the small but energetic Volcan de Tuxtla, which lies a little to the southward of a line joining the rest; next is the vast cone of the peak of Orizaba (No. 9), which attains an elevation of 16,365 feet; and then the still loftier Popocateptl, rising to 17,060 feet. These lie to the east of the city of Mexico; and on its west are the cones of Jorullo and Colima. They are all active; but at no very distant period the snow-clad summits of Iztaccihuatl, of Toluca, and of Tancitara, lying in the same line, were also burning. This chain extends for 140 leagues; and perhaps the volcanoes should be considered as spiracles, all connected with an huge ignited fissure, passing throughout the table-land of Mexico. Five of these mountains penetrate far into the region of perpetual congelation; and from the inaccessible summits of Orizaba and Popocateptl are pinnacles of frozen snow, from which smoke continually issues.

The extent of these eruptions is attested by the prevalence of volcanic rocks over the whole table-land; and the present form of this magnificent plateau would seem to be derived from the accumulation of ignigenous formations in a series of valleys among primary rocks. Tuxtla had a strong eruption in 1793, which covered the roofs of the houses at Oaxaca, Vera Cruz, and Perote, with ashes; and at the latter, which is 196 miles distant, the subterranean noises resembled heavy discharges of artillery.

The formation of the volcano of Jorullo dates not farther back than the year 1759. Until that period, the present site of the volcano was a fertile plain, well cultivated, and producing indigo and the sugar-cane. In the month of June in 1759 subterranean thunderings commenced, accompanied by frequent shocks of earthquakes; and these alarming phenomena continued to terrify the inhabitants for fifty or sixty days. About the beginning of September everything seemed to announce the re-establishment of tranquillity; but on the night of the 28th the horrible subterranean explosions were renewed, and an area of four square miles rose up, like an enormous bladder, to the height of above 500 feet. Those who gained the mountains around saw flames shoot up, from a surface of a square league in extent, and huge fragments of ignited rock hurled into the air through a dense cloud of ashes. The softened surface was seen to undulate like an agitated ocean. The waters of two streams precipitated themselves into the burning chasm, and this seemed to add fresh fury to the flames. Thousands of small burning cones, from six to eight feet high, issued from the softened and inflated surface; and in the midst of these *hornitos* or ovens, which still pour out steam, and emit the sounds of internal ebullition, six vast mountain masses arose, to a height varying from 300 to 1690 feet above the former plain. The most elevated of these is the *Volcan de Jorullo*, which is perpetually burning, and has ejected a vast quantity of ashes and scoriaceous lava, often mingled with fragments of primary rocks. The ashes of this eruption were scattered to a distance of 160 miles. The eruptions of the Jorullo continued till February 1760 without intermission, but they have since become less and less frequent. On this catastrophe Humboldt justly remarks, that an event, "by which so considerable an extent of country entirely changed its appearance, is perhaps one of the most remarkable physical revolutions in the annals of our globe. Geology indicates parts of the ocean where, within the last two thousand years, several small volcanic islands have been formed; but it gives no other example of the formation, from the centre of a thousand burning cones, of a mountain of scoriæ and ashes 1695 feet above the level of the adjoining plain, upwards of thirty-six leagues from the sea, and forty-two leagues from every other active volcano;" and he adds, that though within six days' journey of the Mexican capital, this wonderful event had remained unknown in Europe until the period of his journey (No. 11).

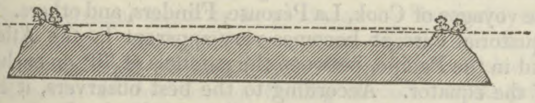
No. 11.

In the works of the South Sea missionary Ellis there is an interesting account of the volcano of Kiraueа, in the Sandwich Islands. The devastating effect of volcanic fire in the island of Hawaiah had been noticed by Captain Cook, but it has been particularly described by Mr Ellis. The route to the present volcano is over a vast waste of naked lava. Instead of a mountain-crater, however, Kiraueа presents a chasm in a plain, perhaps occasioned by the engulfing of the previous elevation. He describes it as a flat area of fifteen or sixteen miles in circumference, sunk from 200 to 400 feet below the level of the country by which he approached Kirauea. In the bottom of this area yawns an immense abyss, in the form of a crescent, about two miles in length from north-east to south-west, and about a mile in breadth at its widest part. One portion presents a flood of glowing matter in a state of terrific ebullition. Fifty-one conical islets, containing as many craters, rise around the edges, or from the surface of the burning lake. Some of them emit flame and smoke, and others occasionally vomit streams of lava, which roll in blazing torrents down their black sides into the boiling flood below. The sides of the gulf just described are perpendicular, and rise from a wide horizontal ledge of solid lava of irregular breadth, but extending completely round the chasm; and beneath this ledge the sides slope to the burning lake, the surface of which appears to be from three hundred to four hundred feet lower.

Besides this volcano, there are several others now extinguished in the island. Of these, one is Mouna Roa, which Captain King calculated, from the position of its perennial line of snow, to be 16,020 feet in height; and the same navigator assigns to another, Mouna Kaah, the vast elevation of 18,000. In a word, the researches of Mr Ellis would lead us to infer that the whole island of Hawaiah, an area of about 4000 square miles, is covered by lavas and other volcanic matters in various stages of decomposition.

The whole islands in the Pacific are divided by Kotzebue into two classes; the *low* and the *elevated*. The former are coral reefs, of which the formation has been so well described by Captains Flinders and Beechy. Their bases would appear to be submarine mountains, which are brought to the surface of the waters by the depositions of the coral animalcules. Captain Beechy examined thirty-two of these islands, the largest of which was thirty miles, the smallest one mile, in diameter. Twenty-nine had lagoons within their centres, which seem once to have existed in them all, until they had been filled up by the operations of the zoophytes. These low coral islands present a singular appearance. (No. 12, a section.) They often form chains, extending for hundreds of miles with little interruption. Their exterior is a border of dead coral rock, and stands a few feet above the waves, on which the seeds of plants, wafted by the sea, soon fix their roots, and speedily a verdant wood encircles the island, whilst its central lagoon is still the habitation of living zoophytes. The elevated islands of the Pacific very generally abound in volcanic products, and numbers of them are still the seats of active volcanoes. Many of them have the appearance of having been raised from the deep by submarine volcanoes; and Mr Lyell has with much force of reasoning contended, that numerous coral islands ought to be considered as the cones of extinguished submarine volcanoes covered over by coralline formations. If we adopt this idea, and extend it to the enormous coral reefs described by Flinders, King, Horsburgh, and Chamisso, the surface of the Pacific must repose upon a prodigious magazine of volcanic energy, which is from time to time destined to increase the surface of the habitable globe. A very extensive line of active volcanoes exists in the Great Eastern Ocean, which has been noticed by Lyell, and forms too remarkable a feature on our globe to be omitted in a sketch of physical geography. It commences in Barren Island, off the coast of the Malayan peninsula; is continued by a chain of active volcanoes through Sumatra, Java, Sumbawa, and Flores; it then turns northward through the Moluccas, the Philippines, Formosa, and Loo-Choo; it passes through Japan, Jesso, and the Kuriles; reaches the peninsula of Kamtschatka, and terminates in the Aleutian Islands, after a course of between 9000 and 10,000 miles, besides the several branches which are sent off to the eastward in the directions of Papua and the Ladrone Islands.

No. 12.



Cause of volcanoes.

The cause of volcanic phenomena is involved in obscurity; but various conjectures have been proposed by geologists. The Neptunian hypothesis has ascribed them to the inflammation of beds of coal, or of other combustibles, in the burning mountain; regarding them as local, or very limited in their range. Lemery's experiment on the heat extricated by moistening a mixture of iron filings and sulphur, and burying it in the earth, was supposed to afford a satisfactory explanation of the manner in which the fire might originally be kindled; and the extinction of volcanoes was supposed to give probability to the local nature of the heating cause. Abbé Breislac modified this hypothesis, by supposing that volcanic fires were fed by collections of petroleum collected in caverns, and set on fire by the chemical action of several other substances. Both these views seem to afford too narrow a basis for the extent of volcanic energy, the apparent connection between distant volcanoes, and the great length of time that some of them are known to have remained in activity. The Huttonians consider volcanoes as spiracles connected with the great source of central heat. (Playfair, 86.)

Another hypothesis has been suggested by the discovery of the metallic bases of the alkalis and earths. Their bases have been supposed to constitute the interior of the earth; and when water finds its way to them, through fissures in its crust, it will be rapidly decomposed, with the extrication of intense heat and the evolution of elastic gases, and thus the phenomena of earthquakes and volcanoes may be produced. This view, originally suggested by Sir Humphry Davy, has been illustrated by Humboldt, and especially by Daubeny, with great ingenuity; and although it has not yet arrived at the state in which, perhaps, we are entitled to denominate it a *theory*, it is an hypothesis which affords a satisfactory explanation of the observed phenomena.

All the enumerated causes have produced and are still producing changes upon the surface of the globe; some of which are general, though slow in their operation, whilst others act much more violently, but are more local in their effects.

Mud and air volcanoes.

Mud and air volcanoes, as they have been termed, appear to owe their existence partly to the disengagement of gases by subterranean fire, but in a great measure to water from a higher level, compelled to pursue a subterranean course, by a thick bed of tenacious clay suddenly escaping by a perpendicular fissure, with a force proportional to the height of the aqueous column. An ingenious explanation of the phenomena of the mud eruptions of Sicily and Italy, on this principle, is given by Dr Daubeny. One of the most noted eruptions of this sort is that of *Macaluba* in Sicily, which in 1777 threw up a vast column of mud, mixed with stones and naphtha, and the disengagement of sulphureous vapours, with much hydrogenous gases. Similar eruptions occur near Catania, and also near Modena. The gaseous exhalations of the *Grotta del Cane* and of the lake of *Ansanto* in the kingdom of Naples, are probably disengaged from mineral bodies by heat. The inflammable air of *Pietra Mala* near Bologna, and of the *petroleum wells* of the country around Baku, on the western shores of the Caspian, are evidently connected with subterranean fire. In the latter district there are strong proofs of volcanic agency still active in the bowels of the earth. The singular eruption which M. Figalgo saw at the northern extremity of Prince William's Sound in North America, belongs to the same class. "The Indians conducted him into a plain covered with snow, where he saw great masses of ice and stones thrown up to prodigious heights in the air with a dreadful noise." (Humboldt.)

Sect. VI.—*Distribution of the Waters of the Globe.*

Natural water never exists in a state of absolute purity. When collected as it descends from the atmosphere, it always contains air; and when derived from springs, lakes, or rivers, it invariably contains more or less of saline ingredients. Dr Henry found in spring-water between four and five per cent. of its bulk of gas, of which nearly three and a half consisted of carbonic acid, and the rest of atmospheric air. Besides the gases, natural waters contain the following salts; muriate of soda, muriate of lime, sulphate of potassa, sulphate of lime or of magnesia, carbonate of lime, and sometimes carbonate of soda. Hail and snow water, when collected at a distance from habitations, contains scarcely any trace of these salts. Rain-water is next in purity; but dew-water is generally contaminated with vegetable matter, as well as with salts. The water of springs usually abounds with these salts, and often with other ingredients. River-water differs much in its purity; but when it flows through a siliceous rock it is often very pure. Lake-water is subject to much contamination; but often, when the lakes are deep and extensive, the water is depurated by subsidence and rest; though stagnant water, when shallow, becomes contaminated with vegetable and animal matter. The water of the ocean contains about three per cent. of saline contents, or one thirty-third part of its weight. The quantity of saline matter appears to increase slightly from the highest latitudes towards the equator. The ocean, from its extent, claims our first attention.

Ocean.
